1 If the best viable function resolves to a function for which multiple declarations were found, and if at least two of these declarations — or the declarations they refer to in the case of *using-declarations* — specify a default argument that made the function viable, the program is ill-formed. [*Example:*

```
namespace A {
  extern "C" void f(int = 5);
}
namespace B {
  extern "C" void f(int = 5);
}

using A::f;
using B::f;

void use() {
  f(3);                           // OK, default argument was not used for viability
  f();                            // Error: found default argument twice
}
```

— *end example*]

13.779.0.1 Implicit conversion sequences [over.best.ics]

1

An *implicit conversion sequence* is a sequence of conversions used to convert an argument in a function call to the type of the corresponding parameter of the function being called. The sequence of conversions is an implicit conversion as defined in Clause 4, which means it is governed by the rules for initialization of an object or reference by a single expression (8.821, 8.2156.1).

1

Implicit conversion sequences are concerned only with the type, cv-qualification, and value category of the argument and how these are converted to match the corresponding properties of the parameter. Other properties, such as the lifetime, storage class, alignment, or accessibility of the argument and whether or not the argument is a bit-field are ignored. So, although an implicit conversion sequence can be defined for a given argument-parameter pair, the conversion from the argument to the parameter might still be ill-formed in the final analysis.

1

A well-formed implicit conversion sequence is one of the following forms:

— a *standard conversion sequence* (13.837.0.0.1),

— a *user-defined conversion sequence* (13.844.0.0.1), or

— an *ellipsis conversion sequence* (13.868.0.0.1).

1

However, if the target is

— the first parameter of a constructor or

— the implicit object parameter of a user-defined conversion function

and the constructor or user-defined conversion function is a candidate by

— 13.354.0.1, when the argument is the temporary in the second step of a class copy-initialization,

— 13.368.0.1, 13.396.0.1, or 13.413.0.1 (in all cases), or

— the second phase of 13.425.0.1 when the initializer list has exactly one element, and the target is the first parameter of a constructor of class `X`, and the conversion is to `X` or reference to (possibly cv-qualified) `X`,

user-defined conversion sequences are not considered. [*Note:* These rules prevent more than one user-defined conversion from being applied during overload resolution, thereby avoiding infinite recursion. — *end note*] [*Example:*

```
struct Y { Y(int); };
struct A { operator int(); };
Y y1 = A();  // error: A::operator int() is not a candidate

struct X { };
struct B { operator X(); };
B b;
X x({b});    // error: B::operator X() is not a candidate
```

— *end example*]

1

For the case where the parameter type is a reference, see 13.870.0.0.1.

1

When the parameter type is not a reference, the implicit conversion sequence models a copy-initialization of the parameter from the argument expression. The implicit conversion sequence is the one required to convert the argument expression to a prvalue of the type of the parameter. [*Note:* When the parameter has a class type, this is a conceptual conversion defined for the purposes of Clause 13; the actual initialization is defined in terms of constructors and is not a conversion. — *end note*] Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion. [*Example:* a parameter of type `A` can be initialized from an argument of type `const A`. The implicit conversion sequence for that case is the identity sequence; it contains no "conversion" from `const A` to `A`. — *end example*] When the parameter has a class type and the argument expression has the same type, the implicit conversion sequence is an identity conversion. When the parameter has a class type and the argument expression has a derived class type, the implicit conversion sequence is a derived-to-base Conversion from the derived class to the base class. [*Note:* There is no such standard conversion; this derived-to-base Conversion exists only in the description of implicit conversion sequences. — *end note*] A derived-to-base Conversion has Conversion rank (13.837.0.0.1).

1 In all contexts, when converting to the implicit object parameter or when converting to the left operand of an assignment operation only standard conversion sequences that create no temporary object for the result are allowed.

2

If no conversions are required to match an argument to a parameter type, the implicit conversion sequence is the standard conversion sequence consisting of the identity conversion (13.837.0.0.1).

1

If no sequence of conversions can be found to convert an argument to a parameter type or the conversion is otherwise ill-formed, an implicit conversion sequence cannot be formed.

1

If several different sequences of conversions exist that each convert the argument to the parameter type, the implicit conversion sequence associated with the parameter is defined to be the unique conversion sequence designated the *ambiguous conversion sequence*. For the purpose of ranking implicit conversion sequences as described in 13.946.0.1, the ambiguous conversion sequence is treated as a user-defined sequence that is indistinguishable from any other user-defined conversion sequence[134]. If a function that uses the ambiguous conversion sequence is selected as the best viable function, the call will be ill-formed because the conversion of one of the arguments in the call is ambiguous.

1 The three forms of implicit conversion sequences mentioned above are defined in the following subclauses.

13.837.0.0.1 Standard conversion sequences [over.ics.scs]

1

Table 12 summarizes the conversions defined in Clause 4 and partitions them into four disjoint categories: Lvalue Transformation, Qualification Adjustment, Promotion, and Conversion. [*Note:* These categories are orthogonal with respect to value category, cv-qualification, and data representation: the Lvalue Transformations do not change the cv-qualification or data representation of the type; the Qualification Adjustments do not change the value category or data representation of the type; and the Promotions and Conversions do not change the value category or cv-qualification of the type. — *end note*]

1

[*Note:* As described in Clause 4, a standard conversion sequence is either the Identity conversion by itself (that is, no conversion) or consists of one to three conversions from the other four categories. At most one conversion from each category is allowed in a single standard conversion sequence. If there are two or more conversions in the sequence, the conversions are applied in the canonical order: **Lvalue Transformation**, **Promotion** or **Conversion**, **Qualification Adjustment**. — *end note*]

1

Each conversion in Table 12 also has an associated rank (Exact Match, Promotion, or Conversion). These are used to rank standard conversion sequences (13.946.0.1). The rank of a conversion sequence is determined by considering the rank of each conversion in the sequence and the rank of any reference binding (13.870.0.0.1).

---

134) The ambiguous conversion sequence is ranked with user-defined conversion sequences because multiple conversion sequences for an argument can exist only if they involve different user-defined conversions. The ambiguous conversion sequence is indistinguishable from any other user-defined conversion sequence because it represents at least two user-defined conversion sequences, each with a different user-defined conversion, and any other user-defined conversion sequence must be indistinguishable from at least one of them.

This rule prevents a function from becoming non-viable because of an ambiguous conversion sequence for one of its parameters. Consider this example,

```
class B;
class A { A (B&);};
class B { operator A (); };
class C { C (B&); };
void f(A) { }
void f(C) { }
B b;
f(b);                          // ambiguous because b → C via constructor and
                               // b → A via constructor or conversion function.
```

If it were not for this rule, `f(A)` would be eliminated as a viable function for the call `f(b)` causing overload resolution to select `f(C)` as the function to call even though it is not clearly the best choice. On the other hand, if an `f(B)` were to be declared then `f(b)` would resolve to that `f(B)` because the exact match with `f(B)` is better than any of the sequences required to match `f(A)`.

If any of those has Conversion rank, the sequence has Conversion rank; otherwise, if any of those has Promotion rank, the sequence has Promotion rank; otherwise, the sequence has Exact Match rank.

Table 12 — Conversions

Conversion	Category	Rank	Subclause
No conversions required	Identity	Exact Match	
Lvalue-to-rvalue conversion	Lvalue Transformation		4.127
Array-to-pointer conversion			4.180
Function-to-pointer conversion			4.220
Qualification conversions	Qualification Adjustment		4.246
Integral promotions	Promotion	Promotion	4.262
Floating point promotion			4.389
Integral conversions	Conversion	Conversion	4.397
Floating point conversions			4.516
Floating-integral conversions			4.532
Pointer conversions			4.579
Pointer to member conversions			4.710
Boolean conversions			4.732

13.844.0.0.1 User-defined conversion sequences [over.ics.user]

1

A user-defined conversion sequence consists of an initial standard conversion sequence followed by a user-defined conversion (12.659) followed by a second standard conversion sequence. If the user-defined conversion is specified by a constructor (12.708.1), the initial standard conversion sequence converts the source type to the type required by the argument of the constructor. If the user-defined conversion is specified by a conversion function (12.742.1), the initial standard conversion sequence converts the source type to the implicit object parameter of the conversion function.

1

The second standard conversion sequence converts the result of the user-defined conversion to the target type for the sequence. Since an implicit conversion sequence is an initialization, the special rules for initialization by user-defined conversion apply when selecting the best user-defined conversion for a user-defined conversion sequence (see 13.562.1 and 13.779.0.1).

1

If the user-defined conversion is specified by a specialization of a conversion function template, the second standard conversion sequence shall have exact match rank.

1

A conversion of an expression of class type to the same class type is given Exact Match rank, and a conversion of an expression of class type to a base class of that type is given Conversion rank, in spite of the fact that a constructor (i.e., a user-defined conversion function) is called for those cases.

13.868.0.0.1 Ellipsis conversion sequences [over.ics.ellipsis]

1

An ellipsis conversion sequence occurs when an argument in a function call is matched with the ellipsis parameter specification of the function called (see 5.955.1).

13.870.0.0.1 Reference binding [over.ics.ref]

1

When a parameter of reference type binds directly (8.2156.1) to an argument expression, the implicit conversion sequence is the identity conversion, unless the argument expression has a type that is a derived class of the parameter type, in which case the implicit conversion sequence is a derived-to-base Conversion (13.779.0.1). [*Example:*

```
struct A {};
struct B : public A {} b;
int f(A&);
int f(B&);
int i = f(b);                    // calls f(B&), an exact match, rather than
                                 // f(A&), a conversion
```

— *end example*] If the parameter binds directly to the result of applying a conversion function to the argument expression, the implicit conversion sequence is a user-defined conversion sequence (13.844.0.0.1), with the second standard conversion sequence either an identity conversion or, if the conversion function returns an entity of a type that is a derived class of the parameter type, a derived-to-base Conversion.

1

When a parameter of reference type is not bound directly to an argument expression, the conversion sequence is the one required to convert the argument expression to the underlying type of the reference according to 13.779.0.1. Conceptually, this conversion sequence corresponds to copy-initializing a temporary of the underlying type with the argument expression. Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion.

1

Except for an implicit object parameter, for which see 13.133.1, a standard conversion sequence cannot be formed if it requires binding an lvalue reference other than a reference to a non-volatile `const` type to an rvalue or binding an rvalue reference to an lvalue other than a function lvalue. [*Note:* This means, for example, that a candidate function cannot be a viable function if it has a non-`const` lvalue reference parameter (other than the implicit object parameter) and the corresponding argument is a temporary or would require one to be created to initialize the lvalue reference (see 8.2156.1). — *end note*]

1

Other restrictions on binding a reference to a particular argument that are not based on the types of the reference and the argument do not affect the formation of a standard conversion sequence, however. [*Example:* a function with an "lvalue reference to `int`" parameter can be a viable candidate even if the corresponding argument is an `int` bit-field. The formation of implicit conversion sequences treats the `int` bit-field as an `int` lvalue and finds an exact match with the parameter. If the function is selected by overload resolution, the call will nonetheless be ill-formed because of the prohibition on binding a non-`const` lvalue reference to a bit-field (8.2156.1). — *end example*]

13.903.0.0.1 List-initialization sequence [over.ics.list]

1

When an argument is an initializer list (8.2435.1), it is not an expression and special rules apply for converting it to a parameter type.

1

If the parameter type is `std::initializer_list<X>` and all the elements of the initializer list can be implicitly converted to `X`, the implicit conversion sequence is the worst conversion necessary to convert an element of the list to `X`, or if the initializer list has no elements, the identity conversion. This conversion can be a user-defined conversion even in the context of a call to an initializer-list constructor. [*Example:*

```
void f(std::initializer_list<int>);
```

```
f( {} );                    // OK: f(initializer_list<int>) identity conversion
f( {1,2,3} );               // OK: f(initializer_list<int>) identity conversion
f( {'a','b'} );             // OK: f(initializer_list<int>) integral promotion
f( {1.0} );                 // error: narrowing

struct A {
  A(std::initializer_list<double>);           // #1
  A(std::initializer_list<complex<double>>);  // #2
  A(std::initializer_list<std::string>);      // #3
};
A a{ 1.0,2.0 };             // OK, uses #1

void g(A);
g({ "foo", "bar" });        // OK, uses #3

typedef int IA[3];
void h(const IA&);
h({ 1, 2, 3 });             // OK: identity conversion
```

— *end example*]

1

Otherwise, if the parameter type is "array of `N X`"[135], if the initializer list has exactly `N` elements or if it has fewer than `N` elements and `X` is default-constructible, and if all the elements of the initializer list can be implicitly converted to `X`, the implicit conversion sequence is the worst conversion necessary to convert an element of the list to `X`.

1

Otherwise, if the parameter is a non-aggregate class `X` and overload resolution per 13.425.0.1 chooses a single best constructor of `X` to perform the initialization of an object of type `X` from the argument initializer list, the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion. If multiple constructors are viable but none is better than the others, the implicit conversion sequence is the ambiguous conversion sequence. User-defined conversions are allowed for conversion of the initializer list elements to the constructor parameter types except as noted in 13.779.0.1. [*Example:*

```
struct A {
  A(std::initializer_list<int>);
};
void f(A);
f( {'a', 'b'} );            // OK: f(A(std::initializer_list<int>)) user-defined conversion

struct B {
  B(int, double);
};
void g(B);
g( {'a', 'b'} );            // OK: g(B(int,double)) user-defined conversion
g( {1.0, 1.0} );            // error: narrowing

void f(B);
f( {'a', 'b'} );            // error: ambiguous f(A) or f(B)

struct C {
```

135) Since there are no parameters of array type, this will only occur as the underlying type of a reference parameter.

```
  C(std::string);
};
void h(C);
h({"foo"});                 // OK: h(C(std::string("foo")))

struct D {
  D(A, C);
};
void i(D);
i({ {1,2}, {"bar"} });      // OK: i(D(A(std::initializer_list<int>{1,2}),C(std::string("bar"))))
```

— *end example*]

1

Otherwise, if the parameter has an aggregate type which can be initialized from the initializer list according to the rules for aggregate initialization (8.1817.1), the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion. [*Example:*

```
struct A {
  int m1;
  double m2;
};

void f(A);
f( {'a', 'b'} );            // OK: f(A(int,double)) user-defined conversion
f( {1.0} );                 // error: narrowing
```

— *end example*]

1

Otherwise, if the parameter is a reference, see 13.870.0.0.1. [*Note:* The rules in this section will apply for initializing the underlying temporary for the reference. — *end note*] [*Example:*

```
struct A {
  int m1;
  double m2;
};

void f(const A&);
f( {'a', 'b'} );            // OK: f(A(int,double)) user-defined conversion
f( {1.0} );                 // error: narrowing

void g(const double &);
g({1});                     // same conversion as int to double
```

— *end example*]

1

Otherwise, if the parameter type is not a class:

— if the initializer list has one element, the implicit conversion sequence is the one required to convert the element to the parameter type; [*Example:*

```
void f(int);
f( {'a'} );                 // OK: same conversion as char to int
f( {1.0} );                 // error: narrowing
```

— *end example*]

— if the initializer list has no elements, the implicit conversion sequence is the identity conversion. [*Example:*

```
void f(int);
f( { } );                    // OK: identity conversion
```

— *end example*]

1

In all cases other than those enumerated above, no conversion is possible.

13.946.0.1 Ranking implicit conversion sequences [over.ics.rank]

1

13.946.0.1 defines a partial ordering of implicit conversion sequences based on the relationships *better conversion sequence* and *better conversion*. If an implicit conversion sequence S1 is defined by these rules to be a better conversion sequence than S2, then it is also the case that S2 is a *worse conversion sequence* than S1. If conversion sequence S1 is neither better than nor worse than conversion sequence S2, S1 and S2 are said to be *indistinguishable conversion sequences*.

1

When comparing the basic forms of implicit conversion sequences (as defined in 13.779.0.1)

— a standard conversion sequence (13.837.0.0.1) is a better conversion sequence than a user-defined conversion sequence or an ellipsis conversion sequence, and

— a user-defined conversion sequence (13.844.0.0.1) is a better conversion sequence than an ellipsis conversion sequence (13.868.0.0.1).

1

Two implicit conversion sequences of the same form are indistinguishable conversion sequences unless one of the following rules applies:

— Standard conversion sequence `S1` is a better conversion sequence than standard conversion sequence `S2` if

  — `S1` is a proper subsequence of `S2` (comparing the conversion sequences in the canonical form defined by 13.837.0.0.1, excluding any Lvalue Transformation; the identity conversion sequence is considered to be a subsequence of any non-identity conversion sequence) or, if not that,

  — the rank of `S1` is better than the rank of `S2`, or `S1` and `S2` have the same rank and are distinguishable by the rules in the paragraph below, or, if not that,

  — `S1` and `S2` are reference bindings (8.2156.1) and neither refers to an implicit object parameter of a non-static member function declared without a *ref-qualifier*, and `S1` binds an rvalue reference to an rvalue and `S2` binds an lvalue reference.

  [*Example:*

```
int i;
int f1();
int&& f2();
int g(const int&);
int g(const int&&);
int j = g(i);                    // calls g(const int&)
int k = g(f1());                 // calls g(const int&&)
int l = g(f2());                 // calls g(const int&&)
```

```
struct A {
  A& operator<<(int);
  void p() &;
  void p() &&;
};
A& operator<<(A&&, char);
A() << 1;                       // calls A::operator<<(int)
A() << 'c';                     // calls operator<<(A&&, char)
A a;
a << 1;                         // calls A::operator<<(int)
a << 'c';                       // calls A::operator<<(int)
A().p();                        // calls A::p()&&
a.p();                          // calls A::p()&
```

— *end example*] or, if not that,

— `S1` and `S2` are reference bindings (8.2156.1) and `S1` binds an lvalue reference to a function lvalue and `S2` binds an rvalue reference to a function lvalue. [*Example:*

```
int f(void(&)());               // #1
int f(void(&&)());              // #2
void g();
int i1 = f(g);                  // calls #1
```

— *end example*] or, if not that,

— `S1` and `S2` differ only in their qualification conversion and yield similar types `T1` and `T2` (4.246), respectively, and the cv-qualification signature of type `T1` is a proper subset of the cv-qualification signature of type `T2`. [*Example:*

```
int f(const volatile int *);
int f(const int *);
int i;
int j = f(&i);                  // calls f(const int*)
```

— *end example*] or, if not that,

— `S1` and `S2` are reference bindings (8.2156.1), and the types to which the references refer are the same type except for top-level cv-qualifiers, and the type to which the reference initialized by `S2` refers is more cv-qualified than the type to which the reference initialized by `S1` refers. [*Example:*

```
int f(const int &);
int f(int &);
int g(const int &);
int g(int);

int i;
int j = f(i);                   // calls f(int &)
int k = g(i);                   // ambiguous

struct X {
  void f() const;
  void f();
};
void g(const X& a, X b) {
  a.f();                        // calls X::f() const
  b.f();                        // calls X::f()
}
```

— *end example*]

— User-defined conversion sequence `U1` is a better conversion sequence than another user-defined conversion sequence `U2` if they contain the same user-defined conversion function or constructor or they initialize the same class in an aggregate initialization and in either case the second standard conversion sequence of `U1` is better than the second standard conversion sequence of `U2`. [*Example:*

```
struct A {
  operator short();
} a;
int f(int);
int f(float);
int i = f(a);                    // calls f(int), because short → int is
                                 // better than short → float.
```

— *end example*]

— List-initialization sequence `L1` is a better conversion sequence than list-initialization sequence `L2` if

  — `L1` converts to `std::initializer_list<X>` for some `X` and `L2` does not, or, if not that,

  — `L1` converts to type "array of `N1 T`", `L2` converts to type "array of `N2 T`", and `N1` is smaller than `N2`.

1

Standard conversion sequences are ordered by their ranks: an Exact Match is a better conversion than a Promotion, which is a better conversion than a Conversion. Two conversion sequences with the same rank are indistinguishable unless one of the following rules applies:

— A conversion that does not convert a pointer, a pointer to member, or `std::nullptr_t` to `bool` is better than one that does.

— A conversion that promotes an enumeration whose underlying type is fixed to its underlying type is better than one that promotes to the promoted underlying type, if the two are different.

— If class `B` is derived directly or indirectly from class `A`, conversion of `B*` to `A*` is better than conversion of `B*` to `void*`, and conversion of `A*` to `void*` is better than conversion of `B*` to `void*`.

— If class `B` is derived directly or indirectly from class `A` and class `C` is derived directly or indirectly from `B`,

  — conversion of `C*` to `B*` is better than conversion of `C*` to `A*`, [*Example:*

```
struct A {};
struct B : public A {};
struct C : public B {};
C* pc;
int f(A*);
int f(B*);
int i = f(pc);                   // calls f(B*)
```

  — *end example*]

  — binding of an expression of type `C` to a reference to type `B` is better than binding an expression of type `C` to a reference to type `A`,

  — conversion of `A::*` to `B::*` is better than conversion of `A::*` to `C::*`,

  — conversion of `C` to `B` is better than conversion of `C` to `A`,

  — conversion of `B*` to `A*` is better than conversion of `C*` to `A*`,

— binding of an expression of type `B` to a reference to type `A` is better than binding an expression of type `C` to a reference to type `A`,

— conversion of `B::*` to `C::*` is better than conversion of `A::*` to `C::*`, and

— conversion of `B` to `A` is better than conversion of `C` to `A`.

[*Note:* Compared conversion sequences will have different source types only in the context of comparing the second standard conversion sequence of an initialization by user-defined conversion (see 13.562.1); in all other contexts, the source types will be the same and the target types will be different. — *end note*]

13.1084 Address of overloaded function [over.over]

1

A use of an overloaded function name without arguments is resolved in certain contexts to a function, a pointer to function or a pointer to member function for a specific function from the overload set. A function template name is considered to name a set of overloaded functions in such contexts. The function selected is the one whose type is identical to the function type of the target type required in the context. [*Note:* That is, the class of which the function is a member is ignored when matching a pointer-to-member-function type. — *end note*] The target can be

— an object or reference being initialized (8.821, 8.2156.1, 8.2435.1),

— the left side of an assignment (5.3483),

— a parameter of a function (5.955.1),

— a parameter of a user-defined operator (13.1122),

— the return value of a function, operator function, or conversion (6.270.2),

— an explicit type conversion (5.1108.1, 5.1443.1, 5.2765), or

— a non-type *template-parameter* (14.364.1).

The overloaded function name can be preceded by the `&` operator. An overloaded function name shall not be used without arguments in contexts other than those listed. [*Note:* Any redundant set of parentheses surrounding the overloaded function name is ignored (5.398). — *end note*]

1

If the name is a function template, template argument deduction is done (14.2407.0.1), and if the argument deduction succeeds, the resulting template argument list is used to generate a single function template specialization, which is added to the set of overloaded functions considered. [*Note:* As described in 14.2075.1, if deduction fails and the function template name is followed by an explicit template argument list, the *template-id* is then examined to see whether it identifies a single function template specialization. If it does, the *template-id* is considered to be an lvalue for that function template specialization. The target type is not used in that determination. — *end note*]

1

Non-member functions and static member functions match targets of type "pointer-to-function" or "reference-to-function." Nonstatic member functions match targets of type "pointer-to-member-function". If a nonstatic member function is selected, the reference to the overloaded function name is required to have the form of a pointer to member as described in 5.1898.1.

1

If more than one function is selected, any function template specializations in the set are eliminated if the set also contains a function that is not a function template specialization, and any given function

template specialization F1 is eliminated if the set contains a second function template specialization whose function template is more specialized than the function template of F1 according to the partial ordering rules of 14.992.0.1. After such eliminations, if any, there shall remain exactly one selected function.

1 [*Example:*

```
int f(double);
int f(int);
int (*pfd)(double) = &f;          // selects f(double)
int (*pfi)(int) = &f;             // selects f(int)
int (*pfe)(...) = &f;             // error: type mismatch
int (&rfi)(int) = f;              // selects f(int)
int (&rfd)(double) = f;           // selects f(double)
void g() {
  (int (*)(int))&f;               // cast expression as selector
}
```

The initialization of pfe is ill-formed because no f() with type int(...) has been declared, and not because of any ambiguity. For another example,

```
struct X {
  int f(int);
  static int f(long);
};

int (X::*p1)(int)  = &X::f;      // OK
int    (*p2)(int)  = &X::f;      // error: mismatch
int    (*p3)(long) = &X::f;      // OK
int (X::*p4)(long) = &X::f;      // error: mismatch
int (X::*p5)(int)  = &(X::f);    // error: wrong syntax for
                                 // pointer to member
int    (*p6)(long) = &(X::f);    // OK
```

— *end example*]

2

[*Note:* If f() and g() are both overloaded functions, the cross product of possibilities must be considered to resolve f(&g), or the equivalent expression f(g). — *end note*]

1 [*Note:* There are no standard conversions (Clause 4) of one pointer-to-function type into another. In particular, even if B is a public base of D, we have

```
D* f();
B* (*p1)() = &f;                 // error

void g(D*);
void (*p2)(B*) = &g;             // error
```

— *end note*]

13.1122 Overloaded operators [over.oper]

1

A function declaration having one of the following *operator-function-id*s as its name declares an *operator function*. A function template declaration having one of the following *operator-function-id*s as its name declares an *operator function template*. A specialization of an operator function template is also an operator function. An operator function is said to *implement* the operator named in its *operator-function-id*.

operator-function-id:
`operator` *operator*

operator: one of

```
new   delete   new[]   delete[]
+     -        *       /        %        ^        &        |        ~
!     =        <       >        +=       -=       *=       /=       %=
^=    &=       |=      <<       >>       >>=      <<=      ==       !=
<=    >=       &&      ||       ++       --       ,        ->*      ->
()    []
```

[*Note:* The last two operators are function call (5.955.1) and subscripting (5.896.1). The operators `new[]`, `delete[]`, `()`, and `[]` are formed from more than one token. — *end note*]

1

Both the unary and binary forms of

```
+    -    *    &
```

can be overloaded.

1

The following operators cannot be overloaded:

```
.    .*    ::    ?:
```

nor can the preprocessing symbols `#` and `##` (Clause 16).

1

Operator functions are usually not called directly; instead they are invoked to evaluate the operators they implement (13.1166.1 – 13.1232.1). They can be explicitly called, however, using the *operator-function-id* as the name of the function in the function call syntax (5.955.1). [*Example:*

```
complex z = a.operator+(b);      // complex z = a+b;
void* p = operator new(sizeof(int)*n);
```

— *end example*]

1

The allocation and deallocation functions, `operator new`, `operator new[]`, `operator delete` and `operator delete[]`, are described completely in 3.2331.1. The attributes and restrictions found in the rest of this subclause do not apply to them unless explicitly stated in 3.2331.1.

1

An operator function shall either be a non-static member function or be a non-member function that has at least one parameter whose type is a class, a reference to a class, an enumeration, or a reference to an enumeration. It is not possible to change the precedence, grouping, or number of operands of operators. The meaning of the operators `=`, (unary) `&`, and `,` (comma), predefined for each type, can be changed for specific class and enumeration types by defining operator functions that implement these operators. Operator functions are inherited in the same manner as other base class functions.

1

The identities among certain predefined operators applied to basic types (for example, `++a` ≡ `a+=1`) need not hold for operator functions. Some predefined operators, such as `+=`, require an operand to be an lvalue when applied to basic types; this is not required by operator functions.

1

An operator function cannot have default arguments (8.545.1), except where explicitly stated below. Operator functions cannot have more or fewer parameters than the number required for the corresponding operator, as described in the rest of this subclause.

1

Operators not mentioned explicitly in subclauses 13.1178.1 through 13.1232.1 act as ordinary unary and binary operators obeying the rules of 13.1166.1 or 13.1170.1.

13.1166.1 Unary operators [over.unary]

1

A prefix unary operator shall be implemented by a non-static member function (9.401) with no parameters or a non-member function with one parameter. Thus, for any prefix unary operator `@`, `@x` can be interpreted as either `x.operator@()` or `operator@(x)`. If both forms of the operator function have been declared, the rules in 13.264.0.1 determine which, if any, interpretation is used. See 13.1232.1 for an explanation of the postfix unary operators `++` and `--`.

1 The unary and binary forms of the same operator are considered to have the same name. [*Note:* Consequently, a unary operator can hide a binary operator from an enclosing scope, and vice versa. — *end note*]

13.1170.1 Binary operators [over.binary]

1

A binary operator shall be implemented either by a non-static member function (9.401) with one parameter or by a non-member function with two parameters. Thus, for any binary operator `@`, `x@y` can be interpreted as either `x.operator@(y)` or `operator@(x,y)`. If both forms of the operator function have been declared, the rules in 13.264.0.1 determine which, if any, interpretation is used.

13.1178.1 Assignment [over.ass]

1

An assignment operator shall be implemented by a non-static member function with exactly one parameter. Because a copy assignment operator `operator=` is implicitly declared for a class if not declared by the user (12.1577), a base class assignment operator is always hidden by the copy assignment operator of the derived class.

1

Any assignment operator, even the copy and move assignment operators, can be virtual. [*Note:* For a derived class `D` with a base class `B` for which a virtual copy/move assignment has been declared, the copy/move assignment operator in `D` does not override `B`'s virtual copy/move assignment operator. [*Example:*

```
struct B {
  virtual int operator= (int);
  virtual B& operator= (const B&);
};
struct D : B {
  virtual int operator= (int);
  virtual D& operator= (const B&);
};

D dobj1;
D dobj2;
B* bptr = &dobj1;
void f() {
```

```
  bptr->operator=(99);          // calls D::operator=(int)
  *bptr = 99;                   // ditto
  bptr->operator=(dobj2);       // calls D::operator=(const B&)
  *bptr = dobj2;                // ditto
  dobj1 = dobj2;                // calls implicitly-declared
                                // D::operator=(const D&)
}
```

— *end example*] — *end note*]

13.1196.1 Function call [over.call]

1

`operator()` shall be a non-static member function with an arbitrary number of parameters. It can have default arguments. It implements the function call syntax

postfix-expression `(` *expression-list*$_{opt}$`)`

where the *postfix-expression* evaluates to a class object and the possibly empty *expression-list* matches the parameter list of an `operator()` member function of the class. Thus, a call `x(arg1,...)` is interpreted as `x.operator()(arg1, ...)` for a class object `x` of type `T` if `T::operator()(T1, T2, T3)` exists and if the operator is selected as the best match function by the overload resolution mechanism (13.562.1).

13.1210.1 Subscripting [over.sub]

1

`operator[]` shall be a non-static member function with exactly one parameter. It implements the subscripting syntax

postfix-expression `[` *expression* `]`

or

postfix-expression `[` *braced-init-list* `]`

Thus, a subscripting expression `x[y]` is interpreted as `x.operator[](y)` for a class object `x` of type `T` if `T::operator[](T1)` exists and if the operator is selected as the best match function by the overload resolution mechanism (13.562.1). [*Example:*

```
struct X {
  Z operator[](std::initializer_list<int>);
};
X x;
x[{1,2,3}] = 7;          // OK: meaning x.operator[]({1,2,3})
int a[10];
a[{1,2,3}] = 7;          // error: built-in subscript operator
```

— *end example*]

13.1217.1 Class member access [over.ref]

1

`operator->` shall be a non-static member function taking no parameters. It implements the class member access syntax that uses `->`.

postfix-expression `->` `template`$_{opt}$ *id-expression*
postfix-expression `->` *pseudo-destructor-name*

An expression `x->m` is interpreted as `(x.operator->())->m` for a class object `x` of type `T` if `T::operator->()` exists and if the operator is selected as the best match function by the overload resolution mechanism (13.88).

13.1232.1 Increment and decrement [over.inc]

1

The user-defined function called `operator++` implements the prefix and postfix `++` operator. If this function is a non-static member function with no parameters, or a non-member function with one parameter, it defines the prefix increment operator `++` for objects of that type. If the function is a non-static member function with one parameter (which shall be of type `int`) or a non-member function with two parameters (the second of which shall be of type `int`), it defines the postfix increment operator `++` for objects of that type. When the postfix increment is called as a result of using the `++` operator, the `int` argument will have value zero.[136] [*Example:*

```
struct X {
  X&   operator++();            // prefix ++a
  X    operator++(int);         // postfix a++
};

struct Y { };
Y&   operator++(Y&);            // prefix ++b
Y    operator++(Y&, int);       // postfix b++

void f(X a, Y b) {
  ++a;                          // a.operator++();
  a++;                          // a.operator++(0);
  ++b;                          // operator++(b);
  b++;                          // operator++(b, 0);

  a.operator++();               // explicit call: like ++a;
  a.operator++(0);              // explicit call: like a++;
  operator++(b);                // explicit call: like ++b;
  operator++(b, 0);             // explicit call: like b++;
}
```

— *end example*]

1 The prefix and postfix decrement operators `--` are handled analogously.

13.1241.1 User-defined literals [over.literal]

literal-operator-id:
`operator` *string-literal identifier*
`operator` *user-defined-string-literal*

1 The *string-literal* or *user-defined-string-literal* in a *literal-operator-id* shall have no *encoding-prefix* and shall contain no characters other than the implicit terminating `'\0'`. The *ud-suffix* of the *user-defined-string-literal* or the *identifier* in a *literal-operator-id* is called a *literal suffix identifier*. [*Note:* some literal suffix identifiers are reserved for future standardization; see 17.424.0.0.1. — *end note*]

2

A declaration whose *declarator-id* is a *literal-operator-id* shall be a declaration of a namespace-scope function or function template (it could be a friend function (11.94)), an explicit instantiation or specialization of a function template, or a *using-declaration* (7.1311.1). A function declared with a *literal-operator-id* is a *literal operator*. A function template declared with a *literal-operator-id* is a *literal operator template*.

1

136) Calling `operator++` explicitly, as in expressions like `a.operator++(2)`, has no special properties: The argument to `operator++` is 2.

The declaration of a literal operator shall have a *parameter-declaration-clause* equivalent to one of the following:

```
const char*
unsigned long long int
long double
char
wchar_t
char16_t
char32_t
const char*, std::size_t
const wchar_t*, std::size_t
const char16_t*, std::size_t
const char32_t*, std::size_t
```

If a parameter has a default argument (8.545.1), the program is ill-formed.

1 A *raw literal operator* is a literal operator with a single parameter whose type is `const char*`.

2

The declaration of a literal operator template shall have an empty *parameter-declaration-clause* and its *template-parameter-list* shall have a single *template-parameter* that is a non-type template parameter pack (14.703.1) with element type `char`.

1 Literal operators and literal operator templates shall not have C language linkage.

2

[*Note:* Literal operators and literal operator templates are usually invoked implicitly through user-defined literals (2.622.1). However, except for the constraints described above, they are ordinary namespace-scope functions and function templates. In particular, they are looked up like ordinary functions and function templates and they follow the same overload resolution rules. Also, they can be declared `inline` or `constexpr`, they may have internal or external linkage, they can be called explicitly, their addresses can be taken, etc. — *end note*]

1 [*Example:*

```
void operator "" _km(long double);                  // OK
string operator "" _i18n(const char*, std::size_t); // OK
template <char...> double operator "" _\u03C0();    // OK: UCN for lowercase pi
float operator ""_e(const char*);                   // OK
float operator ""E(const char*);                    // error: reserved literal suffix (17.424.0.0.1, 2.622.1)
double operator""_Bq(long double);                  // OK: does not use the reserved name _Bq (17.332.0.0.1)
double operator"" _Bq(long double);                 // uses the reserved name _Bq (17.332.0.0.1)
float operator " " B(const char*);                  // error: non-empty string-literal
string operator "" 5X(const char*, std::size_t);    // error: invalid literal suffix identifier
double operator "" _miles(double);                  // error: invalid parameter-declaration-clause
template <char...> int operator "" _j(const char*); // error: invalid parameter-declaration-clause
extern "C" void operator "" _m(long double);        // error: C language linkage
```

— *end example*]

13.1258 Built-in operators [over.built]

1

The candidate operator functions that represent the built-in operators defined in Clause 5 are specified in this subclause. These candidate functions participate in the operator overload resolution process as described in 13.264.0.1 and are used for no other purpose. [*Note:* Because built-in operators take only operands with

non-class type, and operator overload resolution occurs only when an operand expression originally has class or enumeration type, operator overload resolution can resolve to a built-in operator only when an operand has a class type that has a user-defined conversion to a non-class type appropriate for the operator, or when an operand has an enumeration type that can be converted to a type appropriate for the operator. Also note that some of the candidate operator functions given in this subclause are more permissive than the built-in operators themselves. As described in 13.264.0.1, after a built-in operator is selected by overload resolution the expression is subject to the requirements for the built-in operator given in Clause 5, and therefore to any additional semantic constraints given there. If there is a user-written candidate with the same name and parameter types as a built-in candidate operator function, the built-in operator function is hidden and is not included in the set of candidate functions. — *end note*]

1

In this subclause, the term *promoted integral type* is used to refer to those integral types which are preserved by integral promotion (including e.g. `int` and `long` but excluding e.g. `char`). Similarly, the term *promoted arithmetic type* refers to floating types plus promoted integral types. [*Note:* In all cases where a promoted integral type or promoted arithmetic type is required, an operand of enumeration type will be acceptable by way of the integral promotions. — *end note*]

1

For every pair (T, VQ), where T is an arithmetic type, and VQ is either `volatile` or empty, there exist candidate operator functions of the form

```
VQ T& operator++(VQ T&);
T operator++(VQ T&, int);
```

1 For every pair (T, VQ), where T is an arithmetic type other than *bool*, and VQ is either `volatile` or empty, there exist candidate operator functions of the form

```
VQ T& operator--(VQ T&);
T operator--(VQ T&, int);
```

2

For every pair (T, VQ), where T is a cv-qualified or cv-unqualified object type, and VQ is either `volatile` or empty, there exist candidate operator functions of the form

```
T*VQ& operator++(T*VQ&);
T*VQ& operator--(T*VQ&);
T*    operator++(T*VQ&, int);
T*    operator--(T*VQ&, int);
```

1 For every cv-qualified or cv-unqualified object type T, there exist candidate operator functions of the form

```
T&    operator*(T*);
```

2 For every function type T that does not have cv-qualifiers or a *ref-qualifier*, there exist candidate operator functions of the form

```
T&    operator*(T*);
```

3 For every type T there exist candidate operator functions of the form

```
T*    operator+(T*);
```

4 For every promoted arithmetic type T, there exist candidate operator functions of the form

```
T operator+(T);
T operator-(T);
```

5 For every promoted integral type *T*, there exist candidate operator functions of the form

```
T operator~(T);
```

6 For every quintuple (*C1*, *C2*, *T*, *CV1*, *CV2*), where *C2* is a class type, *C1* is the same type as C2 or is a derived class of C2, *T* is an object type or a function type, and *CV1* and *CV2* are *cv-qualifier-seq*s, there exist candidate operator functions of the form

```
CV12 T& operator->*(CV1 C1*, CV2 T C2::*);
```

where *CV12* is the union of *CV1* and *CV2*. The return type is shown for exposition only; see 5.2832 for the determination of the operator's result type.

7

For every pair of promoted arithmetic types *L* and *R*, there exist candidate operator functions of the form

```
LR      operator*(L, R);
LR      operator/(L, R);
LR      operator+(L, R);
LR      operator-(L, R);
bool    operator<(L, R);
bool    operator>(L, R);
bool    operator<=(L, R);
bool    operator>=(L, R);
bool    operator==(L, R);
bool    operator!=(L, R);
```

where *LR* is the result of the usual arithmetic conversions between types *L* and *R*.

1 For every cv-qualified or cv-unqualified object type *T* there exist candidate operator functions of the form

```
T*      operator+(T*, std::ptrdiff_t);
T&      operator[](T*, std::ptrdiff_t);
T*      operator-(T*, std::ptrdiff_t);
T*      operator+(std::ptrdiff_t, T*);
T&      operator[](std::ptrdiff_t, T*);
```

2 For every *T*, where *T* is a pointer to object type, there exist candidate operator functions of the form

```
std::ptrdiff_t   operator-(T, T);
```

3 For every *T*, where *T* is an enumeration type or a pointer type, there exist candidate operator functions of the form

```
bool    operator<(T, T);
bool    operator>(T, T);
bool    operator<=(T, T);
bool    operator>=(T, T);
bool    operator==(T, T);
bool    operator!=(T, T);
```

4 For every pointer to member type *T* or type `std::nullptr_t` there exist candidate operator functions of the form

```
bool    operator==(T, T);
bool    operator!=(T, T);
```

5

For every pair of promoted integral types *L* and *R*, there exist candidate operator functions of the form

```
LR      operator%(L, R);
LR      operator&(L, R);
LR      operator^(L, R);
LR      operator|(L, R);
L       operator<<(L, R);
L       operator>>(L, R);
```

where LR is the result of the usual arithmetic conversions between types L and R.

1 For every triple (L, VQ, R), where L is an arithmetic type, VQ is either `volatile` or empty, and R is a promoted arithmetic type, there exist candidate operator functions of the form

```
VQ L&   operator=(VQ L&, R);
VQ L&   operator*=(VQ L&, R);
VQ L&   operator/=(VQ L&, R);
VQ L&   operator+=(VQ L&, R);
VQ L&   operator-=(VQ L&, R);
```

2 For every pair (T, VQ), where T is any type and VQ is either `volatile` or empty, there exist candidate operator functions of the form

```
T*VQ&   operator=(T*VQ&, T*);
```

3 For every pair (T, VQ), where T is an enumeration or pointer to member type and VQ is either `volatile` or empty, there exist candidate operator functions of the form

```
VQ T&   operator=(VQ T&, T);
```

4 For every pair (T, VQ), where T is a cv-qualified or cv-unqualified object type and VQ is either `volatile` or empty, there exist candidate operator functions of the form

```
T*VQ&   operator+=(T*VQ&, std::ptrdiff_t);
T*VQ&   operator-=(T*VQ&, std::ptrdiff_t);
```

5 For every triple (L, VQ, R), where L is an integral type, VQ is either `volatile` or empty, and R is a promoted integral type, there exist candidate operator functions of the form

```
VQ L&   operator%=(VQ L&, R);
VQ L&   operator<<=(VQ L&, R);
VQ L&   operator>>=(VQ L&, R);
VQ L&   operator&=(VQ L&, R);
VQ L&   operator^=(VQ L&, R);
VQ L&   operator|=(VQ L&, R);
```

6

There also exist candidate operator functions of the form

```
bool    operator!(bool);
bool    operator&&(bool, bool);
bool    operator||(bool, bool);
```

1

For every pair of promoted arithmetic types L and R, there exist candidate operator functions of the form

```
LR      operator?:(bool, L, R);
```

where LR is the result of the usual arithmetic conversions between types L and R. [*Note:* As with all these descriptions of candidate functions, this declaration serves only to describe the built-in operator for purposes of overload resolution. The operator "`?:`" cannot be overloaded. — *end note*]

1

For every type T, where T is a pointer, pointer-to-member, or scoped enumeration type, there exist candidate operator functions of the form

```
T       operator?:(bool, T, T);
```

14 Templates [temp]

1

A *template* defines a family of classes or functions or an alias for a family of types.

template-declaration:
`template` < *template-parameter-list* > *declaration*

template-parameter-list:
template-parameter
template-parameter-list , *template-parameter*

[*Note:* The > token following the *template-parameter-list* of a *template-declaration* may be the product of replacing a >> token by two consecutive > tokens (14.224). — *end note*]

The *declaration* in a *template-declaration* shall

— declare or define a function, a class, or a variable, or

— define a member function, a member class, a member enumeration, or a static data member of a class template or of a class nested within a class template, or

— define a member template of a class or class template, or

— be an *alias-declaration*.

A *template-declaration* is a *declaration*. A *template-declaration* is also a definition if its *declaration* defines a function, a class, a variable, or a static data member. A declaration introduced by a template declaration of a variable is a *variable template*. A variable template at class scope is a *static data member template*.

[*Example:*

```
template<class T>
  constexpr T pi = T(3.1415926535897932385L);
template<class T>
T circular_area(T r) {
  return pi<T> * r * r;
}
struct matrix_constants {
  template<class T>
   using pauli = hermitian_matrix<T, 2>;
  template<class T>
   constexpr pauli<T> sigma1 = { { 0, 1 }, { 1, 0 } };
  template<class T>
   constexpr pauli<T> sigma2 = { { 0, -1i }, { 1i, 0 } };
  template<class T>
   constexpr pauli<T> sigma3 = { { 1, 0 }, { 0, -1 } };
};
```

— *end example*]

1

A *template-declaration* can appear only as a namespace scope or class scope declaration. In a function template declaration, the last component of the *declarator-id* shall not be a *template-id*. [*Note:* That last component may be an *identifier*, an *operator-function-id*, a *conversion-function-id*, or a *literal-operator-id*.

In a class template declaration, if the class name is a *simple-template-id*, the declaration declares a class template partial specialization (14.812.1). — *end note*]

1

In a *template-declaration*, explicit specialization, or explicit instantiation the *init-declarator-list* in the declaration shall contain at most one declarator. When such a declaration is used to declare a class template, no declarator is permitted.

1

A template name has linkage (3.1459). A non-member function template can have internal linkage; any other template name shall have external linkage. Specializations (explicit or implicit) of a template that has internal linkage are distinct from all specializations in other translation units. A template, a template explicit specialization (14.1921.1), and a class template partial specialization shall not have C linkage. Use of a linkage specification other than C or C++ with any of these constructs is conditionally-supported, with implementation-defined semantics. Template definitions shall obey the one definition rule (3.91). [*Note:* Default arguments for function templates and for member functions of class templates are considered definitions for the purpose of template instantiation (14.616) and must also obey the one definition rule. — *end note*]

1

A class template shall not have the same name as any other template, class, function, variable, enumeration, enumerator, namespace, or type in the same scope (3.464), except as specified in (14.812.1). Except that a function template can be overloaded either by non-template functions (8.360.1) with the same name or by other function templates with the same name (14.2662.1), a template name declared in namespace scope or in class scope shall be unique in that scope.

1

A function template, member function of a class template, variable template, or static data member of a class template shall be defined in every translation unit in which it is implicitly instantiated (14.1644.1) unless the corresponding specialization is explicitly instantiated (14.1841.1) in some translation unit; no diagnostic is required.

14.97 Template parameters [temp.param]

1 The syntax for *template-parameter*s is:

template-parameter:
  type-parameter
  parameter-declaration

type-parameter:
  `class` `...`$_{opt}$ *identifier*$_{opt}$
  `class` *identifier*$_{opt}$`=` *type-id*
  `typename` `...`$_{opt}$ *identifier*$_{opt}$
  `typename` *identifier*$_{opt}$`=` *type-id*
  `template` `<` *template-parameter-list* `>` `class` `...`$_{opt}$ *identifier*$_{opt}$
  `template` `<` *template-parameter-list* `>` `class` *identifier*$_{opt}$`=` *id-expression*

[*Note:* The `>` token following the *template-parameter-list* of a *type-parameter* may be the product of replacing a `>>` token by two consecutive `>` tokens (14.224). — *end note*]

2

There is no semantic difference between `class` and `typename` in a *template-parameter*. `typename` followed by an *unqualified-id* names a template type parameter. `typename` followed by a *qualified-id* denotes the type in a non-type [137] *parameter-declaration*. A storage class shall not be specified in a *template-parameter*

137) Since template *template-parameter*s and template *template-argument*s are treated as types for descriptive purposes, the

declaration. Types shall not be defined in a *template-parameter* declaration. [*Note:* A template parameter may be a class template. For example,

```
template<class T> class myarray { /* ... */ };

template<class K, class V, template<class T> class C = myarray>
class Map {
  C<K> key;
  C<V> value;
};
```

— *end note*]

1

A *type-parameter* whose identifier does not follow an ellipsis defines its *identifier* to be a *typedef-name* (if declared with `class` or `typename`) or *template-name* (if declared with `template`) in the scope of the template declaration. [*Note:* Because of the name lookup rules, a *template-parameter* that could be interpreted as either a non-type *template-parameter* or a *type-parameter* (because its *identifier* is the name of an already existing class) is taken as a *type-parameter*. For example,

```
class T { /* ... */ };
int i;

template<class T, T i> void f(T t) {
  T t1 = i;          // template-parameters T and i
  ::T t2 = ::i;      // global namespace members T and i
}
```

Here, the template `f` has a *type-parameter* called `T`, rather than an unnamed non-type *template-parameter* of class `T`. — *end note*]

1

A non-type *template-parameter* shall have one of the following (optionally *cv-qualified*) types:

— integral or enumeration type,

— pointer to object or pointer to function,

— lvalue reference to object or lvalue reference to function,

— pointer to member,

— `std::nullptr_t`.

1

[*Note:* Other types are disallowed either explicitly below or implicitly by the rules governing the form of *template-arguments* (14.326). — *end note*] The top-level *cv-qualifiers* on the *template-parameter* are ignored when determining its type.

1

A non-type non-reference *template-parameter* is a prvalue. It shall not be assigned to or in any other way have its value changed. A non-type non-reference *template-parameter* cannot have its address taken. When a non-type non-reference *template-parameter* is used as an initializer for a reference, a temporary is always used. [*Example:*

terms *non-type parameter* and *non-type argument* are used to refer to non-type, non-template parameters and arguments.

```
template<const X& x, int i> void f() {
  i++;                          // error: change of template-parameter value

  &x;                           // OK
  &i;                           // error: address of non-reference template-parameter

  int& ri = i;                  // error: non-const reference bound to temporary
  const int& cri = i;           // OK: const reference bound to temporary
}
```

— *end example*]

1

A non-type *template-parameter* shall not be declared to have floating point, class, or void type. [*Example:*

```
template<double d> class X;     // error
template<double* pd> class Y;   // OK
template<double& rd> class Z;   // OK
```

— *end example*]

1

A non-type *template-parameter* of type "array of `T`" or "function returning `T`" is adjusted to be of type "pointer to `T`" or "pointer to function returning `T`", respectively. [*Example:*

```
template<int* a>   struct R { /* ... */ };
template<int b[5]> struct S { /* ... */ };
int p;
R<&p> w;                        // OK
S<&p> x;                        // OK due to parameter adjustment
int v[5];
R<v> y;                         // OK due to implicit argument conversion
S<v> z;                         // OK due to both adjustment and conversion
```

— *end example*]

1

A *default template-argument* is a *template-argument* (14.326) specified after `=` in a *template-parameter*. A default *template-argument* may be specified for any kind of *template-parameter* (type, non-type, template) that is not a template parameter pack (14.703.1). A default *template-argument* may be specified in a template declaration. A default *template-argument* shall not be specified in the *template-parameter-lists* of the definition of a member of a class template that appears outside of the member's class. A default *template-argument* shall not be specified in a friend class template declaration. If a friend function template declaration specifies a default *template-argument*, that declaration shall be a definition and shall be the only declaration of the function template in the translation unit.

1

The set of default *template-arguments* available for use with a template declaration or definition is obtained by merging the default arguments from the definition (if in scope) and all declarations in scope in the same way default function arguments are (8.545.1). [*Example:*

```
template<class T1, class T2 = int> class A;
template<class T1 = int, class T2> class A;
```

is equivalent to

```
template<class T1 = int, class T2 = int> class A;
```

— *end example*]

1

If a *template-parameter* of a class template or alias template has a default *template-argument*, each subsequent *template-parameter* shall either have a default *template-argument* supplied or be a template parameter pack. If a *template-parameter* of a primary class template or alias template is a template parameter pack, it shall be the last *template-parameter*. A template parameter pack of a function template shall not be followed by another template parameter unless that template parameter can be deduced from the *parameter-type-list* of the function template or has a default argument (14.2114.1). [*Example:*

```
template<class T1 = int, class T2> class B;   // error

// U can be neither deduced from the parameter-type-list nor specified
template<class... T, class... U> void f() { } // error
template<class... T, class U> void g() { }    // error
```

— *end example*]

1

A *template-parameter* shall not be given default arguments by two different declarations in the same scope. [*Example:*

```
template<class T = int> class X;
template<class T = int> class X { /*... */ }; // error
```

— *end example*]

1 When parsing a default *template-argument* for a non-type *template-parameter*, the first non-nested `>` is taken as the end of the *template-parameter-list* rather than a greater-than operator. [*Example:*

```
template<int i = 3 > 4 >        // syntax error
class X { /* ... */ };

template<int i = (3 > 4) >      // OK
class Y { /* ... */ };
```

— *end example*]

2

A *template-parameter* of a template *template-parameter* is permitted to have a default *template-argument*. When such default arguments are specified, they apply to the template *template-parameter* in the scope of the template *template-parameter*. [*Example:*

```
template <class T = float> struct B {};
template <template <class TT = float> class T> struct A {
  inline void f();
  inline void g();
};
template <template <class TT> class T> void A<T>::f() {
  T<> t;            // error - TT has no default template argument
}
template <template <class TT = char> class T> void A<T>::g() {
    T<> t;          // OK - T<char>
}
```

— *end example*]

1

If a *template-parameter* is a *type-parameter* with an ellipsis prior to its optional *identifier* or is a *parameter-declaration* that declares a parameter pack (8.360.1), then the *template-parameter* is a template parameter pack (14.703.1). A template parameter pack that is a *parameter-declaration* whose type contains one or more unexpanded parameter packs is a pack expansion. Similarly, a template parameter pack that is a *type-parameter* with a *template-parameter-list* containing one or more unexpanded parameter packs is a pack expansion. A template parameter pack that is a pack expansion shall not expand a parameter pack declared in the same *template-parameter-list*. [*Example:*

```
template <class... Types> class Tuple;                  // Types is a template type parameter pack
                                                        // but not a pack expansion
template <class T, int... Dims> struct multi_array;     // Dims is a non-type template parameter pack
                                                        // but not a pack expansion
template<class... T> struct value_holder {
  template<T... Values> struct apply { };               // Values is a non-type template parameter pack
                                                        // and a pack expansion
};
template<class... T, T... Values> struct static_array;// error: Values expands template type parameter
                                                        // pack T within the same template parameter list
```

— *end example*]

14.224 Names of template specializations [temp.names]

1

A template specialization (14.1614) can be referred to by a *template-id*:

simple-template-id:
  template-name < *template-argument-list*$_{opt}$ >

template-id:
  simple-template-id
  operator-function-id < *template-argument-list*$_{opt}$ >
  literal-operator-id < *template-argument-list*$_{opt}$ >

template-name:
  identifier

template-argument-list:
  template-argument ...$_{opt}$
  template-argument-list , *template-argument* ...$_{opt}$

template-argument:
  constant-expression
  type-id
  id-expression

[*Note:* The name lookup rules (3.923) are used to associate the use of a name with a template declaration; that is, to identify a name as a *template-name*. — *end note*]

1

For a *template-name* to be explicitly qualified by the template arguments, the name must be known to refer to a template.

1

After name lookup (3.923) finds that a name is a *template-name* or that an *operator-function-id* or a *literal-operator-id* refers to a set of overloaded functions any member of which is a function template, if this is followed by a <, the < is always taken as the delimiter of a *template-argument-list* and never as the less-than operator. When parsing a *template-argument-list*, the first non-nested >[138] is taken as the ending delimiter

138) A > that encloses the *type-id* of a `dynamic_cast`, `static_cast`, `reinterpret_cast` or `const_cast`, or which encloses the

rather than a greater-than operator. Similarly, the first non-nested `>>` is treated as two consecutive but distinct `>` tokens, the first of which is taken as the end of the *template-argument-list* and completes the *template-id*. [*Note:* The second `>` token produced by this replacement rule may terminate an enclosing *template-id* construct or it may be part of a different construct (e.g. a cast). — *end note*] [*Example:*

```
template<int i> class X { /* ...  */ };

X< 1>2 > x1;                        // syntax error
X<(1>2)> x2;                        // OK

template<class T> class Y { /* ...  */ };
Y<X<1>> x3;                         // OK, same as Y<X<1> > x3;
Y<X<6>>1>> x4;                      // syntax error
Y<X<(6>>1)>> x5;                    // OK
```

— *end example*]

1

When the name of a member template specialization appears after `.` or `->` in a *postfix-expression* or after a *nested-name-specifier* in a *qualified-id*, and the object expression of the *postfix-expression* is type-dependent or the *nested-name-specifier* in the *qualified-id* refers to a dependent type, but the name is not a member of the current instantiation (14.1319.0.1), the member template name must be prefixed by the keyword `template`. Otherwise the name is assumed to name a non-template. [*Example:*

```
struct X {
  template<std::size_t> X* alloc();
  template<std::size_t> static X* adjust();
};
template<class T> void f(T* p) {
  T* p1 = p->alloc<200>();          // ill-formed: < means less than
  T* p2 = p->template alloc<200>(); // OK: < starts template argument list
  T::adjust<100>();                 // ill-formed: < means less than
  T::template adjust<100>();        // OK: < starts template argument list
}
```

— *end example*]

1

A name prefixed by the keyword `template` shall be a *template-id* or the name shall refer to a class template. [*Note:* The keyword `template` may not be applied to non-template members of class templates. — *end note*] [*Note:* As is the case with the `typename` prefix, the `template` prefix is allowed in cases where it is not strictly necessary; i.e., when the *nested-name-specifier* or the expression on the left of the `->` or `.` is not dependent on a *template-parameter*, or the use does not appear in the scope of a template. — *end note*] [*Example:*

```
template <class T> struct A {
  void f(int);
  template <class U> void f(U);
};

template <class T> void f(T t) {
  A<T> a;
  a.template f<>(t);                // OK: calls template
  a.template f(t);                  // error: not a template-id
```

template-arguments of a subsequent *template-id*, is considered nested for the purpose of this description.

```
}

template <class T> struct B {
  template <class T2> struct C { };
};

// OK: T::template C names a class template:
template <class T, template <class X> class TT = T::template C> struct D { };
D<B<int> > db;
```

— *end example*]

1

A *simple-template-id* that names a class template specialization is a *class-name* (Clause 9).

1 A *template-id* that names an alias template specialization is a *type-name*.

14.326 Template arguments [temp.arg]

1

There are three forms of *template-argument*, corresponding to the three forms of *template-parameter*: type, non-type and template. The type and form of each *template-argument* specified in a *template-id* shall match the type and form specified for the corresponding parameter declared by the template in its *template-parameter-list*. When the parameter declared by the template is a template parameter pack (14.703.1), it will correspond to zero or more *template-arguments*. [*Example:*

```
template<class T> class Array {
  T* v;
  int sz;
public:
  explicit Array(int);
  T& operator[](int);
  T& elem(int i) { return v[i]; }
};

Array<int> v1(20);
typedef std::complex<double> dcomplex;  // std::complex is a standard
                                        // library template
Array<dcomplex> v2(30);
Array<dcomplex> v3(40);

void bar() {
  v1[3] = 7;
  v2[3] = v3.elem(4) = dcomplex(7,8);
}
```

— *end example*]

1

In a *template-argument*, an ambiguity between a *type-id* and an expression is resolved to a *type-id*, regardless of the form of the corresponding *template-parameter*.[139] [*Example:*

```
template<class T> void f();
template<int I> void f();
```

139) There is no such ambiguity in a default *template-argument* because the form of the *template-parameter* determines the allowable forms of the *template-argument*.

```
void g() {
  f<int()>();        // int() is a type-id: call the first f()
}
```

— *end example*]

1

The name of a *template-argument* shall be accessible at the point where it is used as a *template-argument*. [*Note:* If the name of the *template-argument* is accessible at the point where it is used as a *template-argument*, there is no further access restriction in the resulting instantiation where the corresponding *template-parameter* name is used. — *end note*] [*Example:*

```
template<class T> class X {
  static T t;
};

class Y {
private:
  struct S { /* ... */ };
  X<S> x;            // OK: S is accessible
                     // X<Y::S> has a static member of type Y::S
                     // OK: even though Y::S is private
};

X<Y::S> y;           // error: S not accessible
```

— *end example*] For a *template-argument* that is a class type or a class template, the template definition has no special access rights to the members of the *template-argument*. [*Example:*

```
template <template <class TT> class T> class A {
  typename T<int>::S s;
};

template <class U> class B {
private:
  struct S { /* ... */ };
};

A<B> b;              // ill-formed: A has no access to B::S
```

— *end example*]

1

When template argument packs or default *template-argument*s are used, a *template-argument* list can be empty. In that case the empty <> brackets shall still be used as the *template-argument-list*. [*Example:*

```
template<class T = char> class String;
String<>* p;                    // OK: String<char>
String* q;                      // syntax error
template<class ... Elements> class Tuple;
Tuple<>* t;                     // OK: Elements is empty
Tuple* u;                       // syntax error
```

— *end example*]

1

An explicit destructor call (12.807) for an object that has a type that is a class template specialization may explicitly specify the *template-arguments*. [*Example:*

```
template<class T> struct A {
  ~A();
};
void f(A<int>* p, A<int>* q) {
  p->A<int>::~A();              // OK: destructor call
  q->A<int>::~A<int>();         // OK: destructor call
}
```

— *end example*]

1

If the use of a *template-argument* gives rise to an ill-formed construct in the instantiation of a template specialization, the program is ill-formed.

1 When the template in a *template-id* is an overloaded function template, both non-template functions in the overload set and function templates in the overload set for which the *template-arguments* do not match the *template-parameters* are ignored. If none of the function templates have matching *template-parameters*, the program is ill-formed.

2

A *template-argument* followed by an ellipsis is a pack expansion (14.703.1).

14.349.1 Template type arguments [temp.arg.type]

1

A *template-argument* for a *template-parameter* which is a type shall be a *type-id*.

1

[*Example:*

```
template <class T> class X { };
template <class T> void f(T t) { }
struct { } unnamed_obj;

void f() {
  struct A { };
  enum { e1 };
  typedef struct { } B;
  B b;
  X<A> x1;          // OK
  X<A*> x2;         // OK
  X<B> x3;          // OK
  f(e1);            // OK
  f(unnamed_obj);   // OK
  f(b);             // OK
}
```

— *end example*] [*Note:* A template type argument may be an incomplete type (3.2955). — *end note*]

1

If a declaration acquires a function type through a type dependent on a *template-parameter* and this causes a declaration that does not use the syntactic form of a function declarator to have function type, the program is ill-formed. [*Example:*

```
template<class T> struct A {
  static T t;
};
typedef int function();
A<function> a;                    // ill-formed: would declare A<function>::t
                                  // as a static member function
```

— *end example*]

14.364.1 Template non-type arguments [temp.arg.nontype]

1

A *template-argument* for a non-type, non-template *template-parameter* shall be one of:

— for a non-type *template-parameter* of integral or enumeration type, a converted constant expression (5.3643) of the type of the *template-parameter*; or

— the name of a non-type *template-parameter*; or

— a constant expression (5.3643) that designates the address of a complete object with static storage duration and external or internal linkage or a function with external or internal linkage, including function templates and function *template-id*s but excluding non-static class members, expressed (ignoring parentheses) as `&` *id-expression*, where the *id-expression* is the name of an object or function, except that the `&` may be omitted if the name refers to a function or array and shall be omitted if the corresponding *template-parameter* is a reference; or

— a constant expression that evaluates to a null pointer value (4.579); or

— a constant expression that evaluates to a null member pointer value (4.710); or

— a pointer to member expressed as described in 5.1898.1; or

— a constant expression of type `std::nullptr_t`.

1

[*Note:* A string literal (2.453.1) does not satisfy the requirements of any of these categories and thus is not an acceptable *template-argument*. [*Example:*

```
template<class T, const char* p> class X {
  /* ... */
};

X<int, "Studebaker"> x1;          // error: string literal as template-argument

const char p[] = "Vivisectionist";
X<int,p> x2;                      // OK
```

— *end example*] — *end note*]

1

[*Note:* Addresses of array elements and names or addresses of non-static class members are not acceptable *template-argument*s. [*Example:*

```
template<int* p> class X { };

int a[10];
```

```
struct S { int m; static int s; } s;

X<&a[2]> x3;                    // error: address of array element
X<&s.m> x4;                     // error: address of non-static member
X<&s.s> x5;                     // error: &S::s must be used
X<&S::s> x6;                    // OK: address of static member
```

— *end example*] — *end note*]

1

[*Note:* Temporaries, unnamed lvalues, and named lvalues with no linkage are not acceptable *template-arguments* when the corresponding *template-parameter* has reference type. [*Example:*

```
template<const int& CRI> struct B { /* ... */ };

B<1> b2;                        // error: temporary would be required for template argument

int c = 1;
B<c> b1;                        // OK
```

— *end example*] — *end note*]

1

The following conversions are performed on each expression used as a non-type *template-argument*. If a non-type *template-argument* cannot be converted to the type of the corresponding *template-parameter* then the program is ill-formed.

— For a non-type *template-parameter* of integral or enumeration type, conversions permitted in a converted constant expression (5.3643) are applied.

— for a non-type *template-parameter* of type pointer to object, qualification conversions (4.246) and the array-to-pointer conversion (4.180) are applied; if the *template-argument* is of type `std::nullptr_t`, the null pointer conversion (4.579) is applied. [*Note:* In particular, neither the null pointer conversion for a zero-valued integer literal (4.579) nor the derived-to-base conversion (4.579) are applied. Although `0` is a valid *template-argument* for a non-type *template-parameter* of integral type, it is not a valid *template-argument* for a non-type *template-parameter* of pointer type. However, both `(int*)0` and `nullptr` are valid *template-arguments* for a non-type *template-parameter* of type "pointer to int." — *end note*]

— For a non-type *template-parameter* of type reference to object, no conversions apply. The type referred to by the reference may be more cv-qualified than the (otherwise identical) type of the *template-argument*. The *template-parameter* is bound directly to the *template-argument*, which shall be an lvalue.

— For a non-type *template-parameter* of type pointer to function, the function-to-pointer conversion (4.220) is applied; if the *template-argument* is of type `std::nullptr_t`, the null pointer conversion (4.579) is applied. If the *template-argument* represents a set of overloaded functions (or a pointer to such), the matching function is selected from the set (13.1084).

— For a non-type *template-parameter* of type reference to function, no conversions apply. If the *template-argument* represents a set of overloaded functions, the matching function is selected from the set (13.1084).

— For a non-type *template-parameter* of type pointer to member function, if the *template-argument* is of type `std::nullptr_t`, the null member pointer conversion (4.710) is applied; otherwise, no conversions apply. If the *template-argument* represents a set of overloaded member functions, the matching member function is selected from the set (13.1084).

— For a non-type *template-parameter* of type pointer to data member, qualification conversions (4.246) are applied; if the *template-argument* is of type `std::nullptr_t`, the null member pointer conversion (4.710) is applied.

[*Example:*

```
template<const int* pci> struct X { /* ... */ };
int ai[10];
X<ai> xi;                       // array to pointer and qualification conversions

struct Y { /* ... */ };
template<const Y& b> struct Z { /* ... */ };
Y y;
Z<y> z;                         // no conversion, but note extra cv-qualification

template<int (&pa)[5]> struct W { /* ... */ };
int b[5];
W<b> w;                         // no conversion

void f(char);
void f(int);

template<void (*pf)(int)> struct A { /* ... */ };

A<&f> a;                        // selects f(int)
```

— *end example*]

14.574.1 Template template arguments [temp.arg.template]

1

A *template-argument* for a template *template-parameter* shall be the name of a class template or an alias template, expressed as *id-expression*. When the *template-argument* names a class template, only primary class templates are considered when matching the template template argument with the corresponding parameter; partial specializations are not considered even if their parameter lists match that of the template template parameter.

1 Any partial specializations (14.812.1) associated with the primary class template or primary variable template are considered when a specialization based on the template *template-parameter* is instantiated. If a specialization is not visible at the point of instantiation, and it would have been selected had it been visible, the program is ill-formed; no diagnostic is required. [*Example:*

```
template<class T> class A {      // primary template
  int x;
};
template<class T> class A<T*> { // partial specialization
  long x;
};
template<template<class U> class V> class C {
  V<int>  y;
  V<int*> z;
};
C<A> c;                          // V<int> within C<A> uses the primary template,
                                 // so c.y.x has type int
                                 // V<int*> within C<A> uses the partial specialization,
                                 // so c.z.x has type long
```

— *end example*]

2 A *template-argument* matches a template *template-parameter* (call it `P`) when each of the template parameters in the *template-parameter-list* of the *template-argument*'s corresponding class template or alias template (call it `A`) matches the corresponding template parameter in the *template-parameter-list* of `P`. Two template parameters match if they are of the same kind (type, non-type, template), for non-type *template-parameter*s, their types are equivalent (14.975.0.1), and for template *template-parameter*s, each of their corresponding *template-parameter*s matches, recursively. When `P`'s *template-parameter-list* contains a template parameter pack (14.703.1), the template parameter pack will match zero or more template parameters or template parameter packs in the *template-parameter-list* of `A` with the same type and form as the template parameter pack in `P` (ignoring whether those template parameters are template parameter packs).

[*Example:*

```
template<class T> class A { /* ... */ };
template<class T, class U = T> class B { /* ... */ };
template <class ... Types> class C { /* ... */ };

template<template<class> class P> class X { /* ... */ };
template<template<class ...> class Q> class Y { /* ... */ };

X<A> xa;            // OK
X<B> xb;            // ill-formed: default arguments for the parameters of a template argument are ignored
X<C> xc;            // ill-formed: a template parameter pack does not match a template parameter

Y<A> ya;            // OK
Y<B> yb;            // OK
Y<C> yc;            // OK
```

— *end example*]

[*Example:*

```
template <class T> struct eval;

template <template <class, class...> class TT, class T1, class... Rest>
struct eval<TT<T1, Rest...>> { };

template <class T1> struct A;
template <class T1, class T2> struct B;
template <int N> struct C;
template <class T1, int N> struct D;
template <class T1, class T2, int N = 17> struct E;

eval<A<int>> eA;                // OK: matches partial specialization of eval
eval<B<int, float>> eB;         // OK: matches partial specialization of eval
eval<C<17>> eC;                 // error: C does not match TT in partial specialization
eval<D<int, 17>> eD;            // error: D does not match TT in partial specialization
eval<E<int, float>> eE;         // error: E does not match TT in partial specialization
```

— *end example*]

14.595 Type equivalence [temp.type]

1

Two *template-id*s refer to the same class, function, or variable if

— their *template-name*s, *operator-function-id*s, or *literal-operator-id*s refer to the same template and

— their corresponding type *template-argument*s are the same type and

— their corresponding non-type template arguments of integral or enumeration type have identical values and

— their corresponding non-type *template-argument*s of pointer type refer to the same external object or function or are both the null pointer value and

— their corresponding non-type *template-argument*s of pointer-to-member type refer to the same class member or are both the null member pointer value and

— their corresponding non-type *template-argument*s of reference type refer to the same external object or function and

— their corresponding template *template-argument*s refer to the same template.

[*Example:*

```
template<class E, int size> class buffer { /* ... */ };
buffer<char,2*512> x;
buffer<char,1024> y;
```

declares `x` and `y` to be of the same type, and

```
template<class T, void(*err_fct)()> class list { /* ... */ };
list<int,&error_handler1> x1;
list<int,&error_handler2> x2;
list<int,&error_handler2> x3;
list<char,&error_handler2> x4;
```

declares `x2` and `x3` to be of the same type. Their type differs from the types of `x1` and `x4`.

```
template<class T> struct X { };
template<class> struct Y { };
template<class T> using Z = Y<T>;
X<Y<int> > y;
X<Z<int> > z;
```

declares `y` and `z` to be of the same type. — *end example*]

1

If an expression *e* involves a template parameter, `decltype(`*e*`)` denotes a unique dependent type. Two such *decltype-specifier*s refer to the same type only if their *expression*s are equivalent (14.975.0.1). [*Note:* however, it may be aliased, e.g., by a *typedef-name*. — *end note*]

14.616 Template declarations [temp.decls]

1 A *template-id*, that is, the *template-name* followed by a *template-argument-list* shall not be specified in the declaration of a primary template declaration. [*Example:*

```
template<class T1, class T2, int I> class A<T1, T2, I> { };      // error
template<class T1, int I> void sort<T1, I>(T1 data[I]);          // error
```

— *end example*] [*Note:* However, this syntax is allowed in class template partial specializations (14.812.1). — *end note*]

2 For purposes of name lookup and instantiation, default arguments and *exception-specification*s of function templates and default arguments and *exception-specification*s of member functions of class templates are considered definitions; each default argument or *exception-specification* is a separate definition which is unrelated to the function template definition or to any other default arguments or *exception-specification*s.

3

Because an *alias-declaration* cannot declare a *template-id*, it is not possible to partially or explicitly specialize an alias template.

14.619.1 Class templates [temp.class]

1 A class *template* defines the layout and operations for an unbounded set of related types. [*Example:* a single class template `List` might provide a common definition for list of `int`, list of `float`, and list of pointers to `Shape`s. — *end example*]

[*Example:* An array class template might be declared like this:

```
template<class T> class Array {
  T* v;
  int sz;
public:
  explicit Array(int);
  T& operator[](int);
  T& elem(int i) { return v[i]; }
};
```

2 The prefix `template <class T>` specifies that a template is being declared and that a *type-name* `T` will be used in the declaration. In other words, `Array` is a parameterized type with `T` as its parameter. — *end example*]

3

When a member function, a member class, a member enumeration, a static data member or a member template of a class template is defined outside of the class template definition, the member definition is defined as a template definition in which the *template-parameter*s are those of the class template. The names of the template parameters used in the definition of the member may be different from the template parameter names used in the class template definition. The template argument list following the class template name in the member definition shall name the parameters in the same order as the one used in the template parameter list of the member. Each template parameter pack shall be expanded with an ellipsis in the template argument list. [*Example:*

```
template<class T1, class T2> struct A {
  void f1();
  void f2();
};

template<class T2, class T1> void A<T2,T1>::f1() { }    // OK
template<class T2, class T1> void A<T1,T2>::f2() { }    // error

template<class ... Types> struct B {
  void f3();
  void f4();
};

template<class ... Types> void B<Types ...>::f3() { }    // OK
template<class ... Types> void B<Types>::f4() { }        // error
```

— *end example*]

1

In a redeclaration, partial specialization, explicit specialization or explicit instantiation of a class template, the *class-key* shall agree in kind with the original class template declaration (7.808.0.1).

14.630.0.1 Member functions of class templates [temp.mem.func]

1

A member function of a class template may be defined outside of the class template definition in which it is declared. [*Example:*

```
template<class T> class Array {
  T* v;
  int sz;
public:
  explicit Array(int);
  T& operator[](int);
  T& elem(int i) { return v[i]; }
};
```

declares three function templates. The subscript function might be defined like this:

```
template<class T> T& Array<T>::operator[](int i) {
  if (i<0 || sz<=i) error("Array: range error");
  return v[i];
}
```

— *end example*]

1

The *template-arguments* for a member function of a class template are determined by the *template-arguments* of the type of the object for which the member function is called. [*Example:* the *template-argument* for `Array<T>::operator[]()` will be determined by the `Array` to which the subscripting operation is applied.

```
Array<int> v1(20);
Array<dcomplex> v2(30);

v1[3] = 7;                      // Array<int>::operator[]()
v2[3] = dcomplex(7,8);          // Array<dcomplex>::operator[]()
```

— *end example*]

14.633.0.1 Member classes of class templates [temp.mem.class]

1

A member class of a class template may be defined outside the class template definition in which it is declared. [*Note:* The member class must be defined before its first use that requires an instantiation (14.1644.1). For example,

```
template<class T> struct A {
  class B;
};
A<int>::B* b1;                  // OK: requires A to be defined but not A::B
template<class T> class A<T>::B { };
A<int>::B  b2;                  // OK: requires A::B to be defined
```

— *end note*]

14.634.0.1 Static data members of class templates [temp.static]

1

A definition for a static data member or static data member template may be provided in a namespace scope enclosing the definition of the static member's class template. [*Example:*

```
template<class T> class X {
  static T s;
};
template<class T> T X<T>::s = 0;

struct limits {
  template<class T>
    static const T min;           // declaration
};

template<class T>
  const T limits::min = { };      // definition
```

— *end example*]

1 An explicit specialization of a static data member declared as an array of unknown bound can have a different bound from its definition, if any. [*Example:*

```
template <class T> struct A {
  static int i[];
};
template <class T> int A<T>::i[4];     // 4 elements
template <> int A<int>::i[] = { 1 };   // OK: 1 element
```

— *end example*]

14.640.0.1 Enumeration members of class templates [temp.mem.enum]

1

An enumeration member of a class template may be defined outside the class template definition. [*Example:*

```
template<class T> struct A {
  enum E : T;
};
A<int> a;
template<class T> enum A<T>::E : T { e1, e2 };
A<int>::E e = A<int>::e1;
```

— *end example*]

14.641.1 Member templates [temp.mem]

1

A template can be declared within a class or class template; such a template is called a member template. A member template can be defined within or outside its class definition or class template definition. A member template of a class template that is defined outside of its class template definition shall be specified with the *template-parameter*s of the class template followed by the *template-parameter*s of the member template. [*Example:*

```
template<class T> struct string {
  template<class T2> int compare(const T2&);
  template<class T2> string(const string<T2>& s) { /* ... */ }
```

```
};

template<class T> template<class T2> int string<T>::compare(const T2& s) {
}
```

— *end example*]

1

A local class of non-closure type shall not have member templates. Access control rules (Clause 11) apply to member template names. A destructor shall not be a member template. A non-template member function (8.360.1) with a given name and type and a member function template of the same name, which could be used to generate a specialization of the same type, can both be declared in a class. When both exist, a use of that name and type refers to the non-template member unless an explicit template argument list is supplied. [*Example:*

```
template <class T> struct A {
  void f(int);
  template <class T2> void f(T2);
};

template <> void A<int>::f(int) { }                    // non-template member function
template <> template <> void A<int>::f<>(int) { }      // member function template specialization

int main() {
  A<char> ac;
  ac.f(1);          // non-template
  ac.f('c');        // template
  ac.f<>(1);        // template
}
```

— *end example*]

1

A member function template shall not be virtual. [*Example:*

```
template <class T> struct AA {
  template <class C> virtual void g(C);   // error
  virtual void f();                       // OK
};
```

— *end example*]

1

A specialization of a member function template does not override a virtual function from a base class. [*Example:*

```
class B {
  virtual void f(int);
};

class D : public B {
  template <class T> void f(T); // does not override B::f(int)
  void f(int i) { f<>(i); }     // overriding function that calls
                                // the template instantiation
};
```

— *end example*]

1

A specialization of a conversion function template is referenced in the same way as a non-template conversion function that converts to the same type. [*Example:*

```
struct A {
  template <class T> operator T*();
};
template <class T> A::operator T*(){ return 0; }
template <> A::operator char*(){ return 0; }    // specialization
template A::operator void*();                   // explicit instantiation

int main() {
  A a;
  int* ip;
  ip = a.operator int*();        // explicit call to template operator
                                 // A::operator int*()
}
```

— *end example*] [*Note:* Because the explicit template argument list follows the function template name, and because conversion member function templates and constructor member function templates are called without using a function name, there is no way to provide an explicit template argument list for these function templates. — *end note*]

1

A specialization of a conversion function template is not found by name lookup. Instead, any conversion function templates visible in the context of the use are considered. For each such operator, if argument deduction succeeds (14.2413.0.1), the resulting specialization is used as if found by name lookup.

1 A *using-declaration* in a derived class cannot refer to a specialization of a conversion function template in a base class.

2

Overload resolution (13.946.0.1) and partial ordering (14.992.0.1) are used to select the best conversion function among multiple specializations of conversion function templates and/or non-template conversion functions.

14.703.1 Variadic templates [temp.variadic]

1

A *template parameter pack* is a template parameter that accepts zero or more template arguments. [*Example:*

```
template<class ... Types> struct Tuple { };

Tuple<> t0;                    // Types contains no arguments
Tuple<int> t1;                 // Types contains one argument: int
Tuple<int, float> t2;          // Types contains two arguments: int and float
Tuple<0> error;                // error: 0 is not a type
```

— *end example*]

1

A *function parameter pack* is a function parameter that accepts zero or more function arguments. [*Example:*

```
template<class ... Types> void f(Types ... args);
```

```
f();                // OK: args contains no arguments
f(1);               // OK: args contains one argument: int
f(2, 1.0);          // OK: args contains two arguments: int and double
```

— *end example*]

1

A *parameter pack* is either a template parameter pack or a function parameter pack.

1

A *pack expansion* consists of a *pattern* and an ellipsis, the instantiation of which produces zero or more instantiations of the pattern in a list (described below). The form of the pattern depends on the context in which the expansion occurs. Pack expansions can occur in the following contexts:

— In a function parameter pack (8.360.1); the pattern is the *parameter-declaration* without the ellipsis.

— In a template parameter pack that is a pack expansion (14.97):
  — if the template parameter pack is a *parameter-declaration*; the pattern is the *parameter-declaration* without the ellipsis;
  — if the template parameter pack is a *type-parameter* with a *template-parameter-list*; the pattern is the corresponding *type-parameter* without the ellipsis.

— In an *initializer-list* (8.821); the pattern is an *initializer-clause*.

— In a *base-specifier-list* (Clause 10); the pattern is a *base-specifier*.

— In a *mem-initializer-list* (12.1026.1) for a *mem-initializer* whose *mem-initializer-id* denotes a base class; the pattern is the *mem-initializer*.

— In a *template-argument-list* (14.326); the pattern is a *template-argument*.

— In a *dynamic-exception-specification* (15.228); the pattern is a *type-id*.

— In an *attribute-list* (7.1546.1); the pattern is an *attribute*.

— In an *alignment-specifier* (7.1556.1); the pattern is the *alignment-specifier* without the ellipsis.

— In a *capture-list* (5.509.1); the pattern is a *capture*.

— In a `sizeof...` expression (5.2075.1); the pattern is an *identifier*.

1

For the purpose of determining whether a parameter pack satisfies a rule regarding entities other than parameter packs, the parameter pack is considered to be the entity that would result from an instantiation of the pattern in which it appears.

[*Example:*

```
template<class ... Types> void f(Types ... rest);
template<class ... Types> void g(Types ... rest) {
  f(&rest ...);      // "&rest ..." is a pack expansion; "&rest" is its pattern
}
```

— *end example*]

1

A parameter pack whose name appears within the pattern of a pack expansion is expanded by that pack expansion. An appearance of the name of a parameter pack is only expanded by the innermost enclosing

pack expansion. The pattern of a pack expansion shall name one or more parameter packs that are not expanded by a nested pack expansion; such parameter packs are called *unexpanded* parameter packs in the pattern. All of the parameter packs expanded by a pack expansion shall have the same number of arguments specified. An appearance of a name of a parameter pack that is not expanded is ill-formed. [*Example:*

```
template<typename...> struct Tuple {};
template<typename T1, typename T2> struct Pair {};

template<class ... Args1> struct zip {
  template<class ... Args2> struct with {
    typedef Tuple<Pair<Args1, Args2> ... > type;
  };
};

typedef zip<short, int>::with<unsigned short, unsigned>::type T1;
    // T1 is Tuple<Pair<short, unsigned short>, Pair<int, unsigned>>
typedef zip<short>::with<unsigned short, unsigned>::type T2;
    // error: different number of arguments specified for Args1 and Args2

template<class ... Args>
  void g(Args ... args) {                // OK: Args is expanded by the function parameter pack args
    f(const_cast<const Args*>(&args)...); // OK: "Args" and "args" are expanded
    f(5 ...);                             // error: pattern does not contain any parameter packs
    f(args);                              // error: parameter pack "args" is not expanded
    f(h(args ...) + args ...);            // OK: first "args" expanded within h, second
                                          // "args" expanded within f
  }
```

— *end example*]

1

The instantiation of a pack expansion that is not a `sizeof...` expression produces a list $\mathtt{E}_1, \mathtt{E}_2, ..., \mathtt{E}_N$, where N is the number of elements in the pack expansion parameters. Each $\mathtt{E}_i$ is generated by instantiating the pattern and replacing each pack expansion parameter with its ith element. Such an element, in the context of the instantiation, is interpreted as follows:

— if the pack is a template parameter pack, the element is a template parameter (14.97) of the corresponding kind (type or non-type) designating the type or value from the template argument; otherwise,

— if the pack is a function parameter pack, the element is an *id-expression* designating the function parameter that resulted from the instantiation of the pattern where the pack is declared.

All of the $\mathtt{E}_i$ become elements in the enclosing list. [*Note:* The variety of list varies with the context: *expression-list*, *base-specifier-list*, *template-argument-list*, etc. — *end note*] When N is zero, the instantiation of the expansion produces an empty list. Such an instantiation does not alter the syntactic interpretation of the enclosing construct, even in cases where omitting the list entirely would otherwise be ill-formed or would result in an ambiguity in the grammar. [*Example:*

```
template<class... T> struct X : T... { };
template<class... T> void f(T... values) {
  X<T...> x(values...);
}

template void f<>();  // OK: X<> has no base classes
                      // x is a variable of type X<> that is value-initialized
```

— *end example*]

1 The instantiation of a `sizeof...` expression (5.2075.1) produces an integral constant containing the number of elements in the parameter pack it expands.

14.755.1 Friends [temp.friend]

1

A friend of a class or class template can be a function template or class template, a specialization of a function template or class template, or a non-template function or class. For a friend function declaration that is not a template declaration:

— if the name of the friend is a qualified or unqualified *template-id*, the friend declaration refers to a specialization of a function template, otherwise,

— if the name of the friend is a *qualified-id* and a matching non-template function is found in the specified class or namespace, the friend declaration refers to that function, otherwise,

— if the name of the friend is a *qualified-id* and a matching function template is found in the specified class or namespace, the friend declaration refers to the deduced specialization of that function template (14.2655.0.1), otherwise,

— the name shall be an *unqualified-id* that declares (or redeclares) a non-template function.

[*Example:*

```
template<class T> class task;
template<class T> task<T>* preempt(task<T>*);

template<class T> class task {
  friend void next_time();
  friend void process(task<T>*);
  friend task<T>* preempt<T>(task<T>*);
  template<class C> friend int func(C);

  friend class task<int>;
  template<class P> friend class frd;
};
```

Here, each specialization of the `task` class template has the function `next_time` as a friend; because `process` does not have explicit *template-arguments*, each specialization of the `task` class template has an appropriately typed function `process` as a friend, and this friend is not a function template specialization; because the friend `preempt` has an explicit *template-argument* `T`, each specialization of the `task` class template has the appropriate specialization of the function template `preempt` as a friend; and each specialization of the `task` class template has all specializations of the function template `func` as friends. Similarly, each specialization of the `task` class template has the class template specialization `task<int>` as a friend, and has all specializations of the class template `frd` as friends. — *end example*]

1

A friend template may be declared within a class or class template. A friend function template may be defined within a class or class template, but a friend class template may not be defined in a class or class template. In these cases, all specializations of the friend class or friend function template are friends of the class or class template granting friendship. [*Example:*

```
class A {
  template<class T> friend class B;                // OK
  template<class T> friend void f(T){ /* ...  */ }  // OK
};
```

— *end example*]

1 A template friend declaration specifies that all specializations of that template, whether they are implicitly instantiated (14.1644.1), partially specialized (14.812.1) or explicitly specialized (14.1921.1), are friends of the class containing the template friend declaration. [*Example:*

```
class X {
  template<class T> friend struct A;
  class Y { };
};

template<class T> struct A { X::Y ab; };            // OK
template<class T> struct A<T*> { X::Y ab; };        // OK
```

— *end example*]

2

When a function is defined in a friend function declaration in a class template, the function is instantiated when the function is odr-used (3.91). The same restrictions on multiple declarations and definitions that apply to non-template function declarations and definitions also apply to these implicit definitions.

1

A member of a class template may be declared to be a friend of a non-template class. In this case, the corresponding member of every specialization of the class template is a friend of the class granting friendship. For explicit specializations the corresponding member is the member (if any) that has the same name, kind (type, function, class template, or function template), template parameters, and signature as the member of the class template instantiation that would otherwise have been generated. [*Example:*

```
template<class T> struct A {
  struct B { };
  void f();
  struct D {
    void g();
  };
};
template<> struct A<int> {
  struct B { };
  int f();
  struct D {
    void g();
  };
};

class C {
  template<class T> friend struct A<T>::B;     // grants friendship to A<int>::B even though
                                               // it is not a specialization of A<T>::B
  template<class T> friend void A<T>::f();     // does not grant friendship to A<int>::f()
                                               // because its return type does not match
  template<class T> friend void A<T>::D::g(); // does not grant friendship to A<int>::D::g()
                                               // because A<int>::D is not a specialization of A<T>::D
};
```

— *end example*]

1 [*Note:* A friend declaration may first declare a member of an enclosing namespace scope (14.1608.1). — *end note*]

2

A friend template shall not be declared in a local class.

1

Friend declarations shall not declare partial specializations. [*Example:*

```
template<class T> class A { };
class X {
  template<class T> friend class A<T*>; // error
};
```

— *end example*]

1

When a friend declaration refers to a specialization of a function template, the function parameter declarations shall not include default arguments, nor shall the inline specifier be used in such a declaration.

14.812.1 Class template partial specializations [temp.class.spec]

1

A *primary* class template declaration is one in which the class template name is an identifier. A template declaration in which the class template name is a *simple-template-id* is a *partial specialization* of the class template named in the *simple-template-id*. A partial specialization of a class template provides an alternative definition of the template that is used instead of the primary definition when the arguments in a specialization match those given in the partial specialization (14.872.0.1). The primary template shall be declared before any specializations of that template. A partial specialization shall be declared before the first use of a class template specialization that would make use of the partial specialization as the result of an implicit or explicit instantiation in every translation unit in which such a use occurs; no diagnostic is required.

1

Each class template partial specialization is a distinct template and definitions shall be provided for the members of a template partial specialization (14.947.0.1).

1

[*Example:*

```
template<class T1, class T2, int I> class A             { };    // #1
template<class T, int I>            class A<T, T*, I>   { };    // #2
template<class T1, class T2, int I> class A<T1*, T2, I> { };    // #3
template<class T>                   class A<int, T*, 5> { };    // #4
template<class T1, class T2, int I> class A<T1, T2*, I> { };    // #5
```

The first declaration declares the primary (unspecialized) class template. The second and subsequent declarations declare partial specializations of the primary template. — *end example*]

1

The template parameters are specified in the angle bracket enclosed list that immediately follows the keyword `template`. For partial specializations, the template argument list is explicitly written immediately following the class template name. For primary templates, this list is implicitly described by the template parameter list. Specifically, the order of the template arguments is the sequence in which they appear in the template parameter list. [*Example:* the template argument list for the primary template in the example above is `<T1, T2, I>`. — *end example*] [*Note:* The template argument list shall not be specified in the primary template declaration. For example,

```
template<class T1, class T2, int I> class A<T1, T2, I>  { };    // error
```

— *end note*]

1

A class template partial specialization may be declared or redeclared in any namespace scope in which its definition may be defined (14.619.1 and 14.641.1). [*Example:*

```
template<class T> struct A {
  struct C {
    template<class T2> struct B { };
  };
};

// partial specialization of A<T>::C::B<T2>
template<class T> template<class T2>
  struct A<T>::C::B<T2*> { };

A<short>::C::B<int*> absip;      // uses partial specialization
```

— *end example*]

1

Partial specialization declarations themselves are not found by name lookup. Rather, when the primary template name is used, any previously-declared partial specializations of the primary template are also considered. One consequence is that a *using-declaration* which refers to a class template does not restrict the set of partial specializations which may be found through the *using-declaration*. [*Example:*

```
namespace N {
  template<class T1, class T2> class A { };          // primary template
}

using N::A;                                  // refers to the primary template

namespace N {
  template<class T> class A<T, T*> { }; // partial specialization
}

A<int,int*> a;                     // uses the partial specialization, which is found through
                                   // the using declaration which refers to the primary template
```

— *end example*]

1

A non-type argument is non-specialized if it is the name of a non-type parameter. All other non-type arguments are specialized.

1

Within the argument list of a class template partial specialization, the following restrictions apply:

— A partially specialized non-type argument expression shall not involve a template parameter of the partial specialization except when the argument expression is a simple *identifier*. [*Example:*

```
template <int I, int J> struct A {};
template <int I> struct A<I+5, I*2> {}; // error

template <int I, int J> struct B {};
template <int I> struct B<I, I> {};     // OK
```

— *end example*]

— The type of a template parameter corresponding to a specialized non-type argument shall not be dependent on a parameter of the specialization. [*Example:*

```
template <class T, T t> struct C {};
template <class T> struct C<T, 1>;                  // error

template< int X, int (*array_ptr)[X] > class A {};
int array[5];
template< int X > class A<X,&array> { };            // error
```

— *end example*]

— The argument list of the specialization shall not be identical to the implicit argument list of the primary template.

— The specialization shall be more specialized than the primary template (14.919.0.1).

— The template parameter list of a specialization shall not contain default template argument values.[140]

— An argument shall not contain an unexpanded parameter pack. If an argument is a pack expansion (14.703.1), it shall be the last argument in the template argument list.

14.872.0.1 Matching of class template partial specializations [temp.class.spec.match]

1

When a class template is used in a context that requires an instantiation of the class, it is necessary to determine whether the instantiation is to be generated using the primary template or one of the partial specializations. This is done by matching the template arguments of the class template specialization with the template argument lists of the partial specializations.

— If exactly one matching specialization is found, the instantiation is generated from that specialization.

— If more than one matching specialization is found, the partial order rules (14.919.0.1) are used to determine whether one of the specializations is more specialized than the others. If none of the specializations is more specialized than all of the other matching specializations, then the use of the class template is ambiguous and the program is ill-formed.

— If no matches are found, the instantiation is generated from the primary template.

1

A partial specialization matches a given actual template argument list if the template arguments of the partial specialization can be deduced from the actual template argument list (14.2114.1). [*Example:*

```
A<int, int, 1>   a1;          // uses #1
A<int, int*, 1>  a2;          // uses #2, T is int, I is 1
A<int, char*, 5> a3;          // uses #4, T is char
A<int, char*, 1> a4;          // uses #5, T1 is int, T2 is char, I is 1
A<int*, int*, 2> a5;          // ambiguous: matches #3 and #5
```

— *end example*]

1

A non-type template argument can also be deduced from the value of an actual template argument of a non-type parameter of the primary template. [*Example:* the declaration of `a2` above. — *end example*]

140) There is no way in which they could be used.

1

In a type name that refers to a class template specialization, (e.g., `A<int, int, 1>`) the argument list shall match the template parameter list of the primary template. The template arguments of a specialization are deduced from the arguments of the primary template.

14.919.0.1 Partial ordering of class template specializations [temp.class.order]

1

For two class template partial specializations, the first is at least as specialized as the second if, given the following rewrite to two function templates, the first function template is at least as specialized as the second according to the ordering rules for function templates (14.992.0.1):

— the first function template has the same template parameters as the first partial specialization and has a single function parameter whose type is a class template specialization with the template arguments of the first partial specialization, and

— the second function template has the same template parameters as the second partial specialization and has a single function parameter whose type is a class template specialization with the template arguments of the second partial specialization.

1 [*Example:*

```
template<int I, int J, class T> class X { };
template<int I, int J>          class X<I, J, int> { }; // #1
template<int I>                 class X<I, I, int> { }; // #2

template<int I, int J> void f(X<I, J, int>);            // A
template<int I>        void f(X<I, I, int>);            // B
```

The partial specialization `#2` is more specialized than the partial specialization `#1` because the function template `B` is more specialized than the function template `A` according to the ordering rules for function templates. — *end example*]

14.947.0.1 Members of class template specializations [temp.class.spec.mfunc]

1

The template parameter list of a member of a class template partial specialization shall match the template parameter list of the class template partial specialization. The template argument list of a member of a class template partial specialization shall match the template argument list of the class template partial specialization. A class template specialization is a distinct template. The members of the class template partial specialization are unrelated to the members of the primary template. Class template partial specialization members that are used in a way that requires a definition shall be defined; the definitions of members of the primary template are never used as definitions for members of a class template partial specialization. An explicit specialization of a member of a class template partial specialization is declared in the same way as an explicit specialization of the primary template. [*Example:*

```
// primary template
template<class T, int I> struct A {
  void f();
};

template<class T, int I> void A<T,I>::f() { }

// class template partial specialization
template<class T> struct A<T,2> {
  void f();
```

```
  void g();
  void h();
};

// member of class template partial specialization
template<class T> void A<T,2>::g() { }

// explicit specialization
template<> void A<char,2>::h() { }

int main() {
  A<char,0> a0;
  A<char,2> a2;
  a0.f();                       // OK, uses definition of primary template's member
  a2.g();                       // OK, uses definition of
                                // partial specialization's member
  a2.h();                       // OK, uses definition of
                                // explicit specialization's member
  a2.f();                       // ill-formed, no definition of f for A<T,2>
                                // the primary template is not used here
}
```

— *end example*]

1

If a member template of a class template is partially specialized, the member template partial specializations are member templates of the enclosing class template; if the enclosing class template is instantiated (14.1644.1, 14.1841.1), a declaration for every member template partial specialization is also instantiated as part of creating the members of the class template specialization. If the primary member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the partial specializations of the member template are ignored for this specialization of the enclosing class template. If a partial specialization of the member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the primary member template and its other partial specializations are still considered for this specialization of the enclosing class template. [*Example:*

```
template<class T> struct A {
  template<class T2> struct B {};                    // #1
  template<class T2> struct B<T2*> {};               // #2
};

template<> template<class T2> struct A<short>::B {};  // #3

A<char>::B<int*>  abcip;  // uses #2
A<short>::B<int*> absip;  // uses #3
A<char>::B<int>  abci;    // uses #1
```

— *end example*]

14.972.1 Function templates [temp.fct]

1 A function template defines an unbounded set of related functions. [*Example:* a family of sort functions might be declared like this:

```
template<class T> class Array { };
template<class T> void sort(Array<T>&);
```

— *end example*]

2

A function template can be overloaded with other function templates and with non-template functions (8.360.1). A non-template function is not related to a function template (i.e., it is never considered to be a specialization), even if it has the same name and type as a potentially generated function template specialization.[141]

14.975.0.1 Function template overloading [temp.over.link]

1

It is possible to overload function templates so that two different function template specializations have the same type. [*Example:*

```
// file1.c
template<class T>
  void f(T*);
void g(int* p) {
  f(p); // calls f<int>(int*)
}
```

```
// file2.c
template<class T>
  void f(T);
void h(int* p) {
  f(p); // calls f<int*>(int*)
}
```

— *end example*]

1

Such specializations are distinct functions and do not violate the one definition rule (3.91).

1

The signature of a function template is defined in 1.27. The names of the template parameters are significant only for establishing the relationship between the template parameters and the rest of the signature. [*Note:* Two distinct function templates may have identical function return types and function parameter lists, even if overload resolution alone cannot distinguish them.

```
template<class T> void f();
template<int I> void f();        // OK: overloads the first template
                                 // distinguishable with an explicit template argument list
```

— *end note*]

1

When an expression that references a template parameter is used in the function parameter list or the return type in the declaration of a function template, the expression that references the template parameter is part of the signature of the function template. This is necessary to permit a declaration of a function template in one translation unit to be linked with another declaration of the function template in another translation unit and, conversely, to ensure that function templates that are intended to be distinct are not linked with one another. [*Example:*

```
template <int I, int J> A<I+J> f(A<I>, A<J>);    // #1
template <int K, int L> A<K+L> f(A<K>, A<L>);    // same as #1
template <int I, int J> A<I-J> f(A<I>, A<J>);    // different from #1
```

— *end example*] [*Note:* Most expressions that use template parameters use non-type template parameters, but it is possible for an expression to reference a type parameter. For example, a template type parameter can be used in the `sizeof` operator. — *end note*]

141) That is, declarations of non-template functions do not merely guide overload resolution of function template specializations with the same name. If such a non-template function is odr-used (3.91) in a program, it must be defined; it will not be implicitly instantiated using the function template definition.

1

Two expressions involving template parameters are considered *equivalent* if two function definitions containing the expressions would satisfy the one definition rule (3.91), except that the tokens used to name the template parameters may differ as long as a token used to name a template parameter in one expression is replaced by another token that names the same template parameter in the other expression. For determining whether two dependent names (14.1257.1) are equivalent, only the name itself is considered, not the result of name lookup in the context of the template. If multiple declarations of the same function template differ in the result of this name lookup, the result for the first declaration is used. [*Example:*

```
template <int I, int J> void f(A<I+J>);          // #1
template <int K, int L> void f(A<K+L>);          // same as #1

template <class T> decltype(g(T())) h();
int g(int);
template <class T> decltype(g(T())) h()          // redeclaration of h() uses the earlier lookup
  { return g(T()); }                             // ...although the lookup here does find g(int)
int i = h<int>();                                // template argument substitution fails; g(int)
                                                 // was not in scope at the first declaration of h()
```

— *end example*] Two expressions involving template parameters that are not equivalent are *functionally equivalent* if, for any given set of template arguments, the evaluation of the expression results in the same value.

1

Two function templates are *equivalent* if they are declared in the same scope, have the same name, have identical template parameter lists, and have return types and parameter lists that are equivalent using the rules described above to compare expressions involving template parameters. Two function templates are *functionally equivalent* if they are equivalent except that one or more expressions that involve template parameters in the return types and parameter lists are functionally equivalent using the rules described above to compare expressions involving template parameters. If a program contains declarations of function templates that are functionally equivalent but not equivalent, the program is ill-formed; no diagnostic is required.

1 [*Note:* This rule guarantees that equivalent declarations will be linked with one another, while not requiring implementations to use heroic efforts to guarantee that functionally equivalent declarations will be treated as distinct. For example, the last two declarations are functionally equivalent and would cause a program to be ill-formed:

```
// Guaranteed to be the same
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+10>);

// Guaranteed to be different
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+11>);

// Ill-formed, no diagnostic required
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+1+2+3+4>);
```

— *end note*]

14.992.0.1 Partial ordering of function templates [temp.func.order]

1

If a function template is overloaded, the use of a function template specialization might be ambiguous because template argument deduction (14.2114.1) may associate the function template specialization with more than one function template declaration. *Partial ordering* of overloaded function template declarations is used in the following contexts to select the function template to which a function template specialization refers:

— during overload resolution for a call to a function template specialization (13.562.1);

— when the address of a function template specialization is taken;

— when a placement operator delete that is a function template specialization is selected to match a placement operator new (3.2428.0.1, 5.2221.1);

— when a friend function declaration (14.755.1), an explicit instantiation (14.1841.1) or an explicit specialization (14.1921.1) refers to a function template specialization.

1

Partial ordering selects which of two function templates is more specialized than the other by transforming each template in turn (see next paragraph) and performing template argument deduction using the function type. The deduction process determines whether one of the templates is more specialized than the other. If so, the more specialized template is the one chosen by the partial ordering process.

1

To produce the transformed template, for each type, non-type, or template template parameter (including template parameter packs (14.703.1) thereof) synthesize a unique type, value, or class template respectively and substitute it for each occurrence of that parameter in the function type of the template. If only one of the function templates is a non-static member of some class `A`, that function template is considered to have a new first parameter inserted in its function parameter list. Given *cv* as the cv-qualifiers of the function template (if any), the new parameter is of type "rvalue reference to *cv* `A`" if the optional *ref-qualifier* of the function template is `&&`, or of type "lvalue reference to *cv* `A`" otherwise. [*Note:* This allows a non-static member to be ordered with respect to a nonmember function and for the results to be equivalent to the ordering of two equivalent nonmembers. — *end note*] [*Example:*

```
struct A { };
template<class T> struct B {
  template<class R> int operator*(R&);              // #1
};

template<class T, class R> int operator*(T&, R&);   // #2

// The declaration of B::operator* is transformed into the equivalent of
// template<class R> int operator*(B<A>&, R&);      // #1a

int main() {
  A a;
  B<A> b;
  b * a;                                            // calls #1a
}
```

— *end example*]

1

Using the transformed function template's function type, perform type deduction against the other template as described in 14.2418.0.1.

[*Example:*

```
template<class T> struct A { A(); };

template<class T> void f(T);
template<class T> void f(T*);
template<class T> void f(const T*);

template<class T> void g(T);
template<class T> void g(T&);

template<class T> void h(const T&);
template<class T> void h(A<T>&);

void m() {
  const int* p;
  f(p);             // f(const T*) is more specialized than f(T) or f(T*)
  float x;
  g(x);             // Ambiguous: g(T) or g(T&)
  A<int> z;
  h(z);             // overload resolution selects h(A<T>&)
  const A<int> z2;
  h(z2);            // h(const T&) is called because h(A<T>&) is not callable
}
```

— *end example*]

1

[*Note:* Since partial ordering in a call context considers only parameters for which there are explicit call arguments, some parameters are ignored (namely, function parameter packs, parameters with default arguments, and ellipsis parameters). [*Example:*

```
template<class T> void f(T);            // #1
template<class T> void f(T*, int=1);    // #2
template<class T> void g(T);            // #3
template<class T> void g(T*, ...);      // #4

int main() {
  int* ip;
  f(ip);            // calls #2
  g(ip);            // calls #4
}
```

— *end example*] [*Example:*

```
template<class T, class U> struct A { };

template<class T, class U> void f(U, A<U, T>* p = 0); // #1
template<         class U> void f(U, A<U, U>* p = 0); // #2
template<class T         > void g(T, T = T());        // #3
template<class T, class... U> void g(T, U ...);       // #4

void h() {
  f<int>(42, (A<int, int>*)0);                         // calls #2
  f<int>(42);                                          // error: ambiguous
  g(42);                                               // error: ambiguous
}
```

— *end example*] [*Example:*

```
template<class T, class... U> void f(T, U...);        // #1
template<class T            > void f(T);              // #2
template<class T, class... U> void g(T*, U...);       // #3
template<class T            > void g(T);              // #4

void h(int i) {
  f(&i);                                              // error: ambiguous
  g(&i);                                              // OK: calls #3
}
```

— *end example*] — *end note*]

14.1031.1 Alias templates [temp.alias]

1

A *template-declaration* in which the *declaration* is an *alias-declaration* (Clause 7) declares the *identifier* to be a *alias template*. An alias template is a name for a family of types. The name of the alias template is a *template-name*.

1

When a *template-id* refers to the specialization of an alias template, it is equivalent to the associated type obtained by substitution of its *template-arguments* for the *template-parameters* in the *type-id* of the alias template. [*Note:* An alias template name is never deduced. — *end note*] [*Example:*

```
template<class T> struct Alloc { /* ... */ };
template<class T> using Vec = vector<T, Alloc<T>>;
Vec<int> v;         // same as vector<int, Alloc<int>> v;

template<class T>
  void process(Vec<T>& v)
  { /* ... */ }

template<class T>
  void process(vector<T, Alloc<T>>& w)
  { /* ... */ }     // error: redefinition

template<template<class> class TT>
  void f(TT<int>);

f(v);               // error: Vec not deduced

template<template<class,class> class TT>
  void g(TT<int, Alloc<int>>);
g(v);               // OK: TT = vector
```

— *end example*]

1

The *type-id* in an alias template declaration shall not refer to the alias template being declared. The type produced by an alias template specialization shall not directly or indirectly make use of that specialization. [*Example:*

```
template <class T> struct A;
template <class T> using B = typename A<T>::U;
template <class T> struct A {
  typedef B<T> U;
```

```
};
B<short> b;          // error: instantiation of B<short> uses own type via A<short>::U
```

— *end example*]

14.1061 Name resolution [temp.res]

1

Three kinds of names can be used within a template definition:

— The name of the template itself, and names declared within the template itself.

— Names dependent on a *template-parameter* (14.1257.1).

— Names from scopes which are visible within the template definition.

1

A name used in a template declaration or definition and that is dependent on a *template-parameter* is assumed not to name a type unless the applicable name lookup finds a type name or the name is qualified by the keyword `typename`. [*Example:*

```
// no B declared here

class X;

template<class T> class Y {
  class Z;                      // forward declaration of member class

  void f() {
    X* a1;                      // declare pointer to X
    T* a2;                      // declare pointer to T
    Y* a3;                      // declare pointer to Y<T>
    Z* a4;                      // declare pointer to Z
    typedef typename T::A TA;
    TA* a5;                     // declare pointer to T's A
    typename T::A* a6;          // declare pointer to T's A
    T::A* a7;                   // T::A is not a type name:
                                // multiply T::A by a7; ill-formed,
                                // no visible declaration of a7
    B* a8;                      // B is not a type name:
                                // multiply B by a8; ill-formed,
                                // no visible declarations of B and a8
  }
};
```

— *end example*]

1

When a *qualified-id* is intended to refer to a type that is not a member of the current instantiation (14.1319.0.1) and its *nested-name-specifier* refers to a dependent type, it shall be prefixed by the keyword `typename`, forming a *typename-specifier*. If the *qualified-id* in a *typename-specifier* does not denote a type, the program is ill-formed.

typename-specifier:
  `typename` *nested-name-specifier identifier*
  `typename` *nested-name-specifier* `template`$_{opt}$ *simple-template-id*

1

If a specialization of a template is instantiated for a set of *template-arguments* such that the *qualified-id* prefixed by `typename` does not denote a type, the specialization is ill-formed. The usual qualified name lookup (3.1236.1) is used to find the *qualified-id* even in the presence of `typename`. [*Example:*

```
struct A {
  struct X { };
  int X;
};
struct B {
  struct X { };
};
template<class T> void f(T t) {
  typename T::X x;
}
void foo() {
  A a;
  B b;
  f(b);              // OK: T::X refers to B::X
  f(a);              // error: T::X refers to the data member A::X not the struct A::X
}
```

— *end example*]

1

A qualified name used as the name in a *mem-initializer-id*, a *base-specifier*, or an *elaborated-type-specifier* is implicitly assumed to name a type, without the use of the `typename` keyword. In a *nested-name-specifier* that immediately contains a *nested-name-specifier* that depends on a template parameter, the *identifier* or *simple-template-id* is implicitly assumed to name a type, without the use of the `typename` keyword. [*Note:* The `typename` keyword is not permitted by the syntax of these constructs. — *end note*]

1 If, for a given set of template arguments, a specialization of a template is instantiated that refers to a *qualified-id* that denotes a type, and the *qualified-id* refers to a member of an unknown specialization, the *qualified-id* shall either be prefixed by `typename` or shall be used in a context in which it implicitly names a type as described above. [*Example:*

```
template <class T> void f(int i) {
  T::x * i;          // T::x must not be a type
}

struct Foo {
  typedef int x;
};

struct Bar {
  static int const x = 5;
};

int main() {
  f<Bar>(1);         // OK
  f<Foo>(1);         // error: Foo::x is a type
}
```

— *end example*]

2

Within the definition of a class template or within the definition of a member of a class template following

the *declarator-id*, the keyword `typename` is not required when referring to the name of a previously declared member of the class template that declares a type. [*Note:* such names can be found using unqualified name lookup (3.952.1), class member lookup (3.1282.0.1) into the current instantiation (14.1319.0.1), or class member access expression lookup (3.1423.1) when the type of the object expression is the current instantiation (14.1390.0.1). — *end note*] [*Example:*

```
template<class T> struct A {
  typedef int B;
  B b;              // OK, no typename required
};
```

— *end example*]

1

Knowing which names are type names allows the syntax of every template to be checked. No diagnostic shall be issued for a template for which a valid specialization can be generated. If no valid specialization can be generated for a template, and that template is not instantiated, the template is ill-formed, no diagnostic required. If every valid specialization of a variadic template requires an empty template parameter pack, the template is ill-formed, no diagnostic required. If a type used in a non-dependent name is incomplete at the point at which a template is defined but is complete at the point at which an instantiation is done, and if the completeness of that type affects whether or not the program is well-formed or affects the semantics of the program, the program is ill-formed; no diagnostic is required. [*Note:* If a template is instantiated, errors will be diagnosed according to the other rules in this Standard. Exactly when these errors are diagnosed is a quality of implementation issue. — *end note*] [*Example:*

```
int j;
template<class T> class X {
  void f(T t, int i, char* p) {
    t = i;          // diagnosed if X::f is instantiated
                    // and the assignment to t is an error
    p = i;          // may be diagnosed even if X::f is
                    // not instantiated
    p = j;          // may be diagnosed even if X::f is
                    // not instantiated
  }
  void g(T t) {
    +;              // may be diagnosed even if X::g is
                    // not instantiated
  }
};

template<class... T> struct A {
  void operator++(int, T... t);                 // error: too many parameters
};
template<class... T> union X : T... { };        // error: union with base class
template<class... T> struct A : T...,  T... { };// error: duplicate base class
```

— *end example*]

1

When looking for the declaration of a name used in a template definition, the usual lookup rules (3.952.1, 3.1092.1) are used for non-dependent names. The lookup of names dependent on the template parameters is postponed until the actual template argument is known (14.1257.1). [*Example:*

```
#include <iostream>
using namespace std;
```

```
template<class T> class Set {
  T* p;
  int cnt;
public:
  Set();
  Set<T>(const Set<T>&);
  void printall() {
    for (int i = 0; i<cnt; i++)
      cout << p[i] << '\n';
  }
};
```

in the example, `i` is the local variable `i` declared in `printall`, `cnt` is the member `cnt` declared in `Set`, and `cout` is the standard output stream declared in `iostream`. However, not every declaration can be found this way; the resolution of some names must be postponed until the actual *template-arguments* are known. For example, even though the name `operator<<` is known within the definition of `printall()` and a declaration of it can be found in `<iostream>`, the actual declaration of `operator<<` needed to print `p[i]` cannot be known until it is known what type `T` is (14.1257.1). — *end example*]

1

If a name does not depend on a *template-parameter* (as defined in 14.1257.1), a declaration (or set of declarations) for that name shall be in scope at the point where the name appears in the template definition; the name is bound to the declaration (or declarations) found at that point and this binding is not affected by declarations that are visible at the point of instantiation. [*Example:*

```
void f(char);

template<class T> void g(T t) {
  f(1);             // f(char)
  f(T(1));          // dependent
  f(t);             // dependent
  dd++;             // not dependent
                    // error: declaration for dd not found
}

enum E { e };
void f(E);

double dd;
void h() {
  g(e);             // will cause one call of f(char) followed
                    // by two calls of f(E)
  g('a');           // will cause three calls of f(char)
}
```

— *end example*]

1 [*Note:* For purposes of name lookup, default arguments and *exception-specifications* of function templates and default arguments and *exception-specifications* of member functions of class templates are considered definitions (14.616). — *end note*]

14.1177.1 Locally declared names [temp.local]

1

Like normal (non-template) classes, class templates have an injected-class-name (Clause 9). The injected-class-name can be used as a *template-name* or a *type-name*. When it is used with a *template-argument-list*, as a *template-argument* for a template *template-parameter*, or as the final identifier in the *elaborated-type-specifier* of a friend class template declaration, it refers to the class template itself. Otherwise, it is equivalent to the *template-name* followed by the *template-parameter*s of the class template enclosed in `<>`.

1

Within the scope of a class template specialization or partial specialization, when the injected-class-name is used as a *type-name*, it is equivalent to the *template-name* followed by the *template-argument*s of the class template specialization or partial specialization enclosed in `<>`. [*Example:*

```
template<template<class> class T> class A { };
template<class T> class Y;
template<> class Y<int> {
  Y* p;                              // meaning Y<int>
  Y<char>* q;                        // meaning Y<char>
  A<Y>* a;                           // meaning A<::Y>
  class B {
    template<class> friend class Y;  // meaning ::Y
  };
};
```

— *end example*]

1

The injected-class-name of a class template or class template specialization can be used either as a *template-name* or a *type-name* wherever it is in scope. [*Example:*

```
template <class T> struct Base {
  Base* p;
};

template <class T> struct Derived: public Base<T> {
  typename Derived::Base* p;    // meaning Derived::Base<T>
};

template<class T, template<class> class U = T::template Base> struct Third { };
Third<Base<int> > t;            // OK: default argument uses injected-class-name as a template
```

— *end example*]

1

A lookup that finds an injected-class-name (10.52) can result in an ambiguity in certain cases (for example, if it is found in more than one base class). If all of the injected-class-names that are found refer to specializations of the same class template, and if the name is used as a *template-name*, the reference refers to the class template itself and not a specialization thereof, and is not ambiguous. [*Example:*

```
template <class T> struct Base { };
template <class T> struct Derived: Base<int>, Base<char> {
  typename Derived::Base b;             // error: ambiguous
  typename Derived::Base<double> d;     // OK
};
```

— *end example*]

1

When the normal name of the template (i.e., the name from the enclosing scope, not the injected-class-name) is used, it always refers to the class template itself and not a specialization of the template. [*Example:*

```
template<class T> class X {
  X* p;             // meaning X<T>
  X<T>* p2;
  X<int>* p3;
  ::X* p4;          // error: missing template argument list
                    // ::X does not refer to the injected-class-name
};
```

— *end example*]

1

A *template-parameter* shall not be redeclared within its scope (including nested scopes). A *template-parameter* shall not have the same name as the template name. [*Example:*

```
template<class T, int i> class Y {
  int T;            // error: template-parameter redeclared
  void f() {
    char T;         // error: template-parameter redeclared
  }
};

template<class X> class X;       // error: template-parameter redeclared
```

— *end example*]

1 In the definition of a member of a class template that appears outside of the class template definition, the name of a member of the class template hides the name of a *template-parameter* of any enclosing class templates (but not a *template-parameter* of the member if the member is a class or function template). [*Example:*

```
template<class T> struct A {
  struct B { /* ...  */ };
  typedef void C;
  void f();
  template<class U> void g(U);
};

template<class B> void A<B>::f() {
  B b;              // A's B, not the template parameter
}

template<class B> template<class C> void A<B>::g(C) {
  B b;              // A's B, not the template parameter
  C c;              // the template parameter C, not A's C
}
```

— *end example*]

2 In the definition of a member of a class template that appears outside of the namespace containing the class template definition, the name of a *template-parameter* hides the name of a member of this namespace. [*Example:*

```
namespace N {
  class C { };
  template<class T> class B {
```

```
    void f(T);
  };
}
template<class C> void N::B<C>::f(C) {
  C b;              // C is the template parameter, not N::C
}
```

— *end example*]

3

In the definition of a class template or in the definition of a member of such a template that appears outside of the template definition, for each base class which does not depend on a *template-parameter* (14.1257.1), if the name of the base class or the name of a member of the base class is the same as the name of a *template-parameter*, the base class name or member name hides the *template-parameter* name (3.875.1). [*Example:*

```
struct A {
  struct B { /* ... */ };
  int a;
  int Y;
};

template<class B, class a> struct X : A {
  B b;              // A's B
  a b;              // error: A's a isn't a type name
};
```

— *end example*]

14.1257.1 Dependent names [temp.dep]

1

Inside a template, some constructs have semantics which may differ from one instantiation to another. Such a construct *depends* on the template parameters. In particular, types and expressions may depend on the type and/or value of template parameters (as determined by the template arguments) and this determines the context for name lookup for certain names. Expressions may be *type-dependent* (on the type of a template parameter) or *value-dependent* (on the value of a non-type template parameter). In an expression of the form:

postfix-expression `(` *expression-list*$_{opt}$`)`

where the *postfix-expression* is an *unqualified-id*, the *unqualified-id* denotes a *dependent name* if

— any of the expressions in the *expression-list* is a pack expansion (14.703.1),

— any of the expressions in the *expression-list* is a type-dependent expression (14.1390.0.1), or

— if the *unqualified-id* is a *template-id* in which any of the template arguments depends on a template parameter.

If an operand of an operator is a type-dependent expression, the operator also denotes a dependent name. Such names are unbound and are looked up at the point of the template instantiation (14.1486.0.1) in both the context of the template definition and the context of the point of instantiation.

1

[*Example:*

```
template<class T> struct X : B<T> {
  typename T::A* pa;
  void f(B<T>* pb) {
    static int i = B<T>::i;
    pb->j++;
  }
};
```

the base class name `B<T>`, the type name `T::A`, the names `B<T>::i` and `pb->j` explicitly depend on the *template-parameter*. — *end example*]

1

In the definition of a class or class template, if a base class depends on a *template-parameter*, the base class scope is not examined during unqualified name lookup either at the point of definition of the class template or member or during an instantiation of the class template or member. [*Example:*

```
typedef double A;
template<class T> class B {
  typedef int A;
};
template<class T> struct X : B<T> {
  A a;              // a has type double
};
```

The type name `A` in the definition of `X<T>` binds to the typedef name defined in the global namespace scope, not to the typedef name defined in the base class `B<T>`. — *end example*] [*Example:*

```
struct A {
  struct B { /* ... */ };
  int a;
  int Y;
};

int a;

template<class T> struct Y : T {
  struct B { /* ... */ };
  B b;                          // The B defined in Y
  void f(int i) { a = i; }      // ::a
  Y* p;                         // Y<T>
};

Y<A> ya;
```

The members `A::B`, `A::a`, and `A::Y` of the template argument `A` do not affect the binding of names in `Y<A>`. — *end example*]

14.1319.0.1 Dependent types [temp.dep.type]

1

A name refers to the *current instantiation* if it is

— in the definition of a class template, a nested class of a class template, a member of a class template, or a member of a nested class of a class template, the injected-class-name (Clause 9) of the class template or nested class,

— in the definition of a primary class template or a member of a primary class template, the name of the class template followed by the template argument list of the primary template (as described below) enclosed in `<>` (or an equivalent template alias specialization),

— in the definition of a nested class of a class template, the name of the nested class referenced as a member of the current instantiation, or

— in the definition of a partial specialization or a member of a partial specialization, the name of the class template followed by the template argument list of the partial specialization enclosed in `<>` (or an equivalent template alias specialization). If the *n*th template parameter is a parameter pack, the *n*th template argument is a pack expansion (14.703.1) whose pattern is the name of the parameter pack.

1 The template argument list of a primary template is a template argument list in which the *n*th template argument has the value of the *n*th template parameter of the class template. If the *n*th template parameter is a template parameter pack (14.703.1), the *n*th template argument is a pack expansion (14.703.1) whose pattern is the name of the template parameter pack.

2 A template argument that is equivalent to a template parameter (i.e., has the same constant value or the same type as the template parameter) can be used in place of that template parameter in a reference to the current instantiation. In the case of a non-type template argument, the argument must have been given the value of the template parameter and not an expression in which the template parameter appears as a subexpression. [*Example:*

```
template <class T> class A {
  A* p1;                        // A is the current instantiation
  A<T>* p2;                     // A<T> is the current instantiation
  A<T*> p3;                     // A<T*> is not the current instantiation
  ::A<T>* p4;                   // ::A<T> is the current instantiation
  class B {
    B* p1;                      // B is the current instantiation
    A<T>::B* p2;                // A<T>::B is the current instantiation
    typename A<T*>::B* p3;      // A<T*>::B is not the
                                // current instantiation
  };
};

template <class T> class A<T*> {
  A<T*>* p1;                    // A<T*> is the current instantiation
  A<T>* p2;                     // A<T> is not the current instantiation
};

template <class T1, class T2, int I> struct B {
  B<T1, T2, I>* b1;             // refers to the current instantiation
  B<T2, T1, I>* b2;             // not the current instantiation
  typedef T1 my_T1;
  static const int my_I = I;
  static const int my_I2 = I+0;
  static const int my_I3 = my_I;
  B<my_T1, T2, my_I>* b3;       // refers to the current instantiation
  B<my_T1, T2, my_I2>* b4;      // not the current instantiation
  B<my_T1, T2, my_I3>* b5;      // refers to the current instantiation
};
```

— *end example*]

3

A name is a *member of the current instantiation* if it is

— An unqualified name that, when looked up, refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [*Note:* This can only occur when looking up a name in a scope enclosed by the definition of a class template. — *end note*]

— A *qualified-id* in which the *nested-name-specifier* refers to the current instantiation and that, when looked up, refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [*Note:* if no such member is found, and the current instantiation has any dependent base classes, then the *qualified-id* is a member of an unknown specialization; see below. — *end note*]

— An *id-expression* denoting the member in a class member access expression (5.1194.1) for which the type of the object expression is the current instantiation, and the *id-expression*, when looked up (3.1423.1), refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [*Note:* if no such member is found, and the current instantiation has any dependent base classes, then the *id-expression* is a member of an unknown specialization; see below. — *end note*]

[*Example:*

```
template <class T> class A {
  static const int i = 5;
  int n1[i];         // i refers to a member of the current instantiation
  int n2[A::i];      // A::i refers to a member of the current instantiation
  int n3[A<T>::i];   // A<T>::i refers to a member of the current instantiation
  int f();
};

template <class T> int A<T>::f() {
  return i;          // i refers to a member of the current instantiation
}
```

— *end example*]

A name is a *dependent member of the current instantiation* if it is a member of the current instantiation that, when looked up, refers to at least one member of a class that is the current instantiation.

1

A name is a *member of an unknown specialization* if it is

— A *qualified-id* in which the *nested-name-specifier* names a dependent type that is not the current instantiation.

— A *qualified-id* in which the *nested-name-specifier* refers to the current instantiation, the current instantiation has at least one dependent base class, and name lookup of the *qualified-id* does not find any member of a class that is the current instantiation or a non-dependent base class thereof.

— An *id-expression* denoting the member in a class member access expression (5.1194.1) in which either

  — the type of the object expression is the current instantiation, the current instantiation has at least one dependent base class, and name lookup of the *id-expression* does not find a member of a class that is the current instantiation or a non-dependent base class thereof; or

  — the type of the object expression is dependent and is not the current instantiation.

1

If a *qualified-id* in which the *nested-name-specifier* refers to the current instantiation is not a member of the current instantiation or a member of an unknown specialization, the program is ill-formed even if the

template containing the *qualified-id* is not instantiated; no diagnostic required. Similarly, if the *id-expression* in a class member access expression for which the type of the object expression is the current instantiation does not refer to a member of the current instantiation or a member of an unknown specialization, the program is ill-formed even if the template containing the member access expression is not instantiated; no diagnostic required. [*Example:*

```
template<class T> class A {
  typedef int type;
  void f() {
    A<T>::type i;            // OK: refers to a member of the current instantiation
    typename A<T>::other j;  // error: neither a member of the current instantiation nor
                             // a member of an unknown specialization
  }
};
```

— *end example*]

1

If, for a given set of template arguments, a specialization of a template is instantiated that refers to a member of the current instantiation with a *qualified-id* or class member access expression, the name in the *qualified-id* or class member access expression is looked up in the template instantiation context. If the result of this lookup differs from the result of name lookup in the template definition context, name lookup is ambiguous. [*Note:* the result of name lookup differs only when the member of the current instantiation was found in a non-dependent base class of the current instantiation and a member with the same name is also introduced by the substitution for a dependent base class of the current instantiation. — *end note*]

1

A type is dependent if it is

— a template parameter,

— a member of an unknown specialization,

— a nested class or enumeration that is a dependent member of the current instantiation,

— a cv-qualified type where the cv-unqualified type is dependent,

— a compound type constructed from any dependent type,

— an array type constructed from any dependent type or whose size is specified by a constant expression that is value-dependent,

— a *simple-template-id* in which either the template name is a template parameter or any of the template arguments is a dependent type or an expression that is type-dependent or value-dependent, or

— denoted by `decltype(`*expression*`)`, where *expression* is type-dependent (14.1390.0.1).

1 [*Note:* Because typedefs do not introduce new types, but instead simply refer to other types, a name that refers to a typedef that is a member of the current instantiation is dependent only if the type referred to is dependent. — *end note*]

14.1390.0.1 Type-dependent expressions [temp.dep.expr]

1

Except as described below, an expression is type-dependent if any subexpression is type-dependent.

1

`this` is type-dependent if the class type of the enclosing member function is dependent (14.1319.0.1).

1

An *id-expression* is type-dependent if it contains

— an *identifier* associated by name lookup with one or more declarations declared with a dependent type,

— an *identifier* associated by name lookup with one or more declarations of member functions of the current instantiation declared with a return type that contains a placeholder type (7.832.0.1),

— a *template-id* that is dependent,

— a *conversion-function-id* that specifies a dependent type, or

— a *nested-name-specifier* or a *qualified-id* that names a member of an unknown specialization;

or if it names a dependent member of the current instantiation that is a static data member of type "array of unknown bound of `T`" for some `T` (14.634.0.1). Expressions of the following forms are type-dependent only if the type specified by the *type-id*, *simple-type-specifier* or *new-type-id* is dependent, even if any subexpression is type-dependent:

simple-type-specifier `(` *expression-list*$_{opt}$`)`
`::`$_{opt}$ `new` *new-placement*$_{opt}$ *new-type-id* *new-initializer*$_{opt}$
`::`$_{opt}$ `new` *new-placement*$_{opt}$`(` *type-id* `)` *new-initializer*$_{opt}$
`dynamic_cast <` *type-id* `> (` *expression* `)`
`static_cast <` *type-id* `> (` *expression* `)`
`const_cast <` *type-id* `> (` *expression* `)`
`reinterpret_cast <` *type-id* `> (` *expression* `)`
`(` *type-id* `)` *cast-expression*

1

Expressions of the following forms are never type-dependent (because the type of the expression cannot be dependent):

literal
postfix-expression `.` *pseudo-destructor-name*
postfix-expression `->` *pseudo-destructor-name*
`sizeof` *unary-expression*
`sizeof (` *type-id* `)`
`sizeof ... (` *identifier* `)`
`alignof (` *type-id* `)`
`typeid (` *expression* `)`
`typeid (` *type-id* `)`
`::`$_{opt}$ `delete` *cast-expression*
`::`$_{opt}$ `delete [ ]` *cast-expression*
`throw` *assignment-expression*$_{opt}$
`noexcept (` *expression* `)`

[*Note:* For the standard library macro `offsetof`, see 18.2. — *end note*]

1

A class member access expression (5.1194.1) is type-dependent if the expression refers to a member of the current instantiation and the type of the referenced member is dependent, or the class member access expression refers to a member of an unknown specialization. [*Note:* In an expression of the form `x.y` or `xp->y` the type of the expression is usually the type of the member `y` of the class of `x` (or the class pointed to by `xp`). However, if `x` or `xp` refers to a dependent type that is not the current instantiation, the type of

`y` is always dependent. If `x` or `xp` refers to a non-dependent type or refers to the current instantiation, the type of `y` is the type of the class member access expression. — *end note*]

14.1430.0.1 Value-dependent expressions [temp.dep.constexpr]

1

Except as described below, a constant expression is value-dependent if any subexpression is value-dependent.

1

An *id-expression* is value-dependent if:

— it is a name declared with a dependent type,

— it is the name of a non-type template parameter,

— it names a member of an unknown specialization,

— it names a static data member that is a dependent member of the current instantiation and is not initialized in a *member-declarator*,

— it names a static member function that is a dependent member of the current instantiation, or

— it is a constant with literal type and is initialized with an expression that is value-dependent.

Expressions of the following form are value-dependent if the *unary-expression* or *expression* is type-dependent or the *type-id* is dependent:

`sizeof` *unary-expression*
`sizeof (` *type-id* `)`
`typeid (` *expression* `)`
`typeid (` *type-id* `)`
`alignof (` *type-id* `)`
`noexcept (` *expression* `)`

[*Note:* For the standard library macro `offsetof`, see 18.2. — *end note*]

1 Expressions of the following form are value-dependent if either the *type-id* or *simple-type-specifier* is dependent or the *expression* or *cast-expression* is value-dependent:

simple-type-specifier `(` *expression-list*$_{opt}$ `)`
`static_cast <` *type-id* `> (` *expression* `)`
`const_cast <` *type-id* `> (` *expression* `)`
`reinterpret_cast <` *type-id* `> (` *expression* `)`
`(` *type-id* `)` *cast-expression*

2 Expressions of the following form are value-dependent:

`sizeof ... (` *identifier* `)`

3

An expression of the form `&`*qualified-id* where the *qualified-id* names a dependent member of the current instantiation is value-dependent.

14.1439.0.1 Dependent template arguments [temp.dep.temp]

1

A type *template-argument* is dependent if the type it specifies is dependent.

1

A non-type *template-argument* is dependent if its type is dependent or the constant expression it specifies is value-dependent.

1 Furthermore, a non-type *template-argument* is dependent if the corresponding non-type *template-parameter* is of reference or pointer type and the *template-argument* designates or points to a member of the current instantiation or a member of a dependent type.

2 A template *template-argument* is dependent if it names a *template-parameter* or is a *qualified-id* that refers to a member of an unknown specialization.

14.1444.1 Non-dependent names [temp.nondep]

1

Non-dependent names used in a template definition are found using the usual name lookup and bound at the point they are used. [*Example:*

```
void g(double);
void h();

template<class T> class Z {
public:
  void f() {
    g(1);           // calls g(double)
    h++;            // ill-formed: cannot increment function;
                    // this could be diagnosed either here or
                    // at the point of instantiation
  }
};

void g(int);        // not in scope at the point of the template
                    // definition, not considered for the call g(1)
```

— *end example*]

14.1452.1 Dependent name resolution [temp.dep.res]

1

In resolving dependent names, names from the following sources are considered:

— Declarations that are visible at the point of definition of the template.

— Declarations from namespaces associated with the types of the function arguments both from the instantiation context (14.1486.0.1) and from the definition context.

14.1486.0.1 Point of instantiation [temp.point]

1

For a function template specialization, a member function template specialization, or a specialization for a member function or static data member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization and the context from which it is referenced depends on a template parameter, the point of instantiation of the specialization is the point of instantiation of the enclosing specialization. Otherwise, the point of instantiation for such a specialization immediately follows the namespace scope declaration or definition that refers to the specialization.

1

If a function template or member function of a class template is called in a way which uses the definition of a default argument of that function template or member function, the point of instantiation of the default argument is the point of instantiation of the function template or member function specialization.

1 For an *exception-specification* of a function template specialization or specialization of a member function of a class template, if the *exception-specification* is implicitly instantiated because it is needed by another template specialization and the context that requires it depends on a template parameter, the point of instantiation of the *exception-specification* is the point of instantiation of the specialization that requires it. Otherwise, the point of instantiation for such an *exception-specification* immediately follows the namespace scope declaration or definition that requires the *exception-specification*.

2

For a class template specialization, a class member template specialization, or a specialization for a class member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization, if the context from which the specialization is referenced depends on a template parameter, and if the specialization is not instantiated previous to the instantiation of the enclosing template, the point of instantiation is immediately before the point of instantiation of the enclosing template. Otherwise, the point of instantiation for such a specialization immediately precedes the namespace scope declaration or definition that refers to the specialization.

1

If a virtual function is implicitly instantiated, its point of instantiation is immediately following the point of instantiation of its enclosing class template specialization.

1

An explicit instantiation definition is an instantiation point for the specialization or specializations specified by the explicit instantiation.

1

The instantiation context of an expression that depends on the template arguments is the set of declarations with external linkage declared prior to the point of instantiation of the template specialization in the same translation unit.

1

A specialization for a function template, a member function template, or of a member function or static data member of a class template may have multiple points of instantiations within a translation unit, and in addition to the points of instantiation described above, for any such specialization that has a point of instantiation within the translation unit, the end of the translation unit is also considered a point of instantiation. A specialization for a class template has at most one point of instantiation within a translation unit. A specialization for any template may have points of instantiation in multiple translation units. If two different points of instantiation give a template specialization different meanings according to the one definition rule (3.91), the program is ill-formed, no diagnostic required.

14.1532.0.1 Candidate functions [temp.dep.candidate]

1

For a function call where the *postfix-expression* is a dependent name, the candidate functions are found using the usual lookup rules (3.952.1, 3.1092.1) except that:

— For the part of the lookup using unqualified name lookup (3.952.1), only function declarations from the template definition context are found.

— For the part of the lookup using associated namespaces (3.1092.1), only function declarations found in either the template definition context or the template instantiation context are found.

If the call would be ill-formed or would find a better match had the lookup within the associated namespaces considered all the function declarations with external linkage introduced in those namespaces in all translation units, not just considering those declarations found in the template definition and template instantiation contexts, then the program has undefined behavior.

14.1608.1 Friend names declared within a class template [temp.inject]

1

Friend classes or functions can be declared within a class template. When a template is instantiated, the names of its friends are treated as if the specialization had been explicitly declared at its point of instantiation.

1

As with non-template classes, the names of namespace-scope friend functions of a class template specialization are not visible during an ordinary lookup unless explicitly declared at namespace scope (11.94). Such names may be found under the rules for associated classes (3.1092.1).[142] [*Example:*

```
template<typename T> struct number {
  number(int);
  friend number gcd(number x, number y) { return 0; };
};

void g() {
  number<double> a(3), b(4);
  a = gcd(a,b);      // finds gcd because number<double> is an
                     // associated class, making gcd visible
                     // in its namespace (global scope)
  b = gcd(3,4);      // ill-formed; gcd is not visible
}
```

— *end example*]

14.1614 Template instantiation and specialization [temp.spec]

1

The act of instantiating a function, a class, a member of a class template or a member template is referred to as *template instantiation*.

1

A function instantiated from a function template is called an instantiated function. A class instantiated from a class template is called an instantiated class. A member function, a member class, a member enumeration, or a static data member of a class template instantiated from the member definition of the class template is called, respectively, an instantiated member function, member class, member enumeration, or static data member. A member function instantiated from a member function template is called an instantiated member function. A member class instantiated from a member class template is called an instantiated member class.

1

An explicit specialization may be declared for a function template, a class template, a member of a class template or a member template. An explicit specialization declaration is introduced by `template<>`. In an explicit specialization declaration for a class template, a member of a class template or a class member template, the name of the class that is explicitly specialized shall be a *simple-template-id*. In the explicit specialization declaration for a function template or a member function template, the name of the function or member function explicitly specialized may be a *template-id*. [*Example:*

```
template<class T = int> struct A {
  static int x;
};
template<class U> void g(U) { }
```

142) Friend declarations do not introduce new names into any scope, either when the template is declared or when it is instantiated.

```
template<> struct A<double> { };        // specialize for T == double
template<> struct A<> { };              // specialize for T == int
template<> void g(char) { }             // specialize for U == char
                                        // U is deduced from the parameter type
template<> void g<int>(int) { }         // specialize for U == int
template<> int A<char>::x = 0;          // specialize for T == char

template<class T = int> struct B {
  static int x;
};
template<> int B<>::x = 1;              // specialize for T == int
```

— *end example*]

1

An instantiated template specialization can be either implicitly instantiated (14.1644.1) for a given argument list or be explicitly instantiated (14.1841.1). A specialization is a class, function, or class member that is either instantiated or explicitly specialized (14.1921.1).

1

For a given template and a given set of *template-arguments*,

— an explicit instantiation definition shall appear at most once in a program,

— an explicit specialization shall be defined at most once in a program (according to 3.91), and

— both an explicit instantiation and a declaration of an explicit specialization shall not appear in a program unless the explicit instantiation follows a declaration of the explicit specialization.

An implementation is not required to diagnose a violation of this rule.

1

Each class template specialization instantiated from a template has its own copy of any static members. [*Example:*

```
template<class T> class X {
  static T s;
};
template<class T> T X<T>::s = 0;
X<int> aa;
X<char*> bb;
```

`X<int>` has a static member `s` of type `int` and `X<char*>` has a static member `s` of type `char*`. — *end example*]

14.1644.1 Implicit instantiation [temp.inst]

1

Unless a class template specialization has been explicitly instantiated (14.1841.1) or explicitly specialized (14.1921.1), the class template specialization is implicitly instantiated when the specialization is referenced in a context that requires a completely-defined object type or when the completeness of the class type affects the semantics of the program. The implicit instantiation of a class template specialization causes the implicit instantiation of the declarations, but not of the definitions, default arguments, or *exception-specifications* of the class member functions, member classes, scoped member enumerations, static data members and member templates; and it causes the implicit instantiation of the definitions of unscoped

member enumerations and member anonymous unions. However, for the purpose of determining whether an instantiated redeclaration of a member is valid according to 9.194, a declaration that corresponds to a definition in the template is considered to be a definition. [*Example:*

```
template<class T, class U>
struct Outer {
  template<class X, class Y> struct Inner;
  template<class Y> struct Inner<T, Y>;          // #1a
  template<class Y> struct Inner<T, Y> { };      // #1b; OK: valid redeclaration of #1a
  template<class Y> struct Inner<U, Y> { };      // #2
};

Outer<int, int> outer;                           // error at #2
```

`Outer<int, int>::Inner<int, Y>` is redeclared at #1b. (It is not defined but noted as being associated with a definition in `Outer<T, U>`.) #2 is also a redeclaration of #1a. It is noted as associated with a definition, so it is an invalid redeclaration of the same partial specialization. — *end example*]

1

Unless a member of a class template or a member template has been explicitly instantiated or explicitly specialized, the specialization of the member is implicitly instantiated when the specialization is referenced in a context that requires the member definition to exist; in particular, the initialization (and any associated side-effects) of a static data member does not occur unless the static data member is itself used in a way that requires the definition of the static data member to exist.

1

Unless a function template specialization has been explicitly instantiated or explicitly specialized, the function template specialization is implicitly instantiated when the specialization is referenced in a context that requires a function definition to exist. Unless a call is to a function template explicit specialization or to a member function of an explicitly specialized class template, a default argument for a function template or a member function of a class template is implicitly instantiated when the function is called in a context that requires the value of the default argument.

1

[*Example:*

```
template<class T> struct Z {
  void f();
  void g();
};

void h() {
  Z<int> a;          // instantiation of class Z<int> required
  Z<char>* p;        // instantiation of class Z<char> not required
  Z<double>* q;      // instantiation of class Z<double> not required

  a.f();             // instantiation of Z<int>::f() required
  p->g();            // instantiation of class Z<char> required, and
                     // instantiation of Z<char>::g() required
}
```

Nothing in this example requires `class Z<double>`, `Z<int>::g()`, or `Z<char>::f()` to be implicitly instantiated. — *end example*]

1 Unless a variable template specialization has been explicitly instantiated or explicitly specialized, the variable template specialization is implicitly instantiated when the specialization is used. A default template

argument for a variable template is implicitly instantiated when the variable template is referenced in a context that requires the value of the default argument.

2

A class template specialization is implicitly instantiated if the class type is used in a context that requires a completely-defined object type or if the completeness of the class type might affect the semantics of the program. [*Note:* In particular, if the semantics of an expression depend on the member or base class lists of a class template specialization, the class template specialization is implicitly generated. For instance, deleting a pointer to class type depends on whether or not the class declares a destructor, and conversion between pointer to class types depends on the inheritance relationship between the two classes involved. — *end note*] [*Example:*

```
template<class T> class B { /* ... */ };
template<class T> class D : public B<T> { /* ... */ };

void f(void*);
void f(B<int>*);

void g(D<int>* p, D<char>* pp, D<double>* ppp) {
  f(p);              // instantiation of D<int> required: call f(B<int>*)
  B<char>* q = pp;   // instantiation of D<char> required:
                     // convert D<char>* to B<char>*
  delete ppp;        // instantiation of D<double> required
}
```

— *end example*]

1

If the overload resolution process can determine the correct function to call without instantiating a class template definition, it is unspecified whether that instantiation actually takes place. [*Example:*

```
template <class T> struct S {
  operator int();
};

void f(int);
void f(S<int>&);
void f(S<float>);

void g(S<int>& sr) {
  f(sr);             // instantiation of S<int> allowed but not required
                     // instantiation of S<float> allowed but not required
};
```

— *end example*]

1

If an implicit instantiation of a class template specialization is required and the template is declared but not defined, the program is ill-formed. [*Example:*

```
template<class T> class X;

X<char> ch;          // error: definition of X required
```

— *end example*]

1

The implicit instantiation of a class template does not cause any static data members of that class to be implicitly instantiated.

1

If a function template or a member function template specialization is used in a way that involves overload resolution, a declaration of the specialization is implicitly instantiated (14.2662.1).

1

An implementation shall not implicitly instantiate a function template, a variable template, a member template, a non-virtual member function, a member class, or a static data member of a class template that does not require instantiation. It is unspecified whether or not an implementation implicitly instantiates a virtual member function of a class template if the virtual member function would not otherwise be instantiated. The use of a template specialization in a default argument shall not cause the template to be implicitly instantiated except that a class template may be instantiated where its complete type is needed to determine the correctness of the default argument. The use of a default argument in a function call causes specializations in the default argument to be implicitly instantiated.

1

Implicitly instantiated class, function, and variable template specializations are placed in the namespace where the template is defined. Implicitly instantiated specializations for members of a class template are placed in the namespace where the enclosing class template is defined. Implicitly instantiated member templates are placed in the namespace where the enclosing class or class template is defined. [*Example:*

```
namespace N {
  template<class T> class List {
  public:
    T* get();
  };
}

template<class K, class V> class Map {
public:
  N::List<V> lt;
  V get(K);
};

void g(Map<const char*,int>& m) {
  int i = m.get("Nicholas");
}
```

a call of `lt.get()` from `Map<const char*,int>::get()` would place `List<int>::get()` in the namespace `N` rather than in the global namespace. — *end example*]

1

If a function template `f` is called in a way that requires a default argument to be used, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the default argument is done as if the default argument had been an initializer used in a function template specialization with the same scope, the same template parameters and the same access as that of the function template `f` used at that point, except that the scope in which a closure type is declared (5.509.1) – and therefore its associated namespaces – remain as determined from the context of the definition for the default argument. This analysis is called *default argument instantiation*. The instantiated default argument is then used as the argument of `f`.

1

Each default argument is instantiated independently. [*Example:*

```
template<class T> void f(T x, T y = ydef(T()), T z = zdef(T()));

class  A { };

A zdef(A);

void g(A a, A b, A c) {
  f(a, b, c);        // no default argument instantiation
  f(a, b);           // default argument z = zdef(T()) instantiated
  f(a);              // ill-formed; ydef is not declared
}
```

— *end example*]

1 The *exception-specification* of a function template specialization is not instantiated along with the function declaration; it is instantiated when needed (15.228). If such an *exception-specification* is needed but has not yet been instantiated, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the *exception-specification* is done as if it were being done as part of instantiating the declaration of the specialization at that point.

2 [*Note:* 14.1486.0.1 defines the point of instantiation of a template specialization. — *end note*]

3

There is an implementation-defined quantity that specifies the limit on the total depth of recursive instantiations, which could involve more than one template. The result of an infinite recursion in instantiation is undefined. [*Example:*

```
template<class T> class X {
  X<T>* p;           // OK
  X<T*> a;           // implicit generation of X<T> requires
                     // the implicit instantiation of X<T*> which requires
                     // the implicit instantiation of X<T**> which ...
};
```

— *end example*]

14.1841.1 Explicit instantiation [temp.explicit]

1

A class, function, variable, or member template specialization can be explicitly instantiated from its template. A member function, member class or static data member of a class template can be explicitly instantiated from the member definition associated with its class template. An explicit instantiation of a function template or member function of a class template shall not use the `inline` or `constexpr` specifiers.

1

The syntax for explicit instantiation is:

explicit-instantiation:
  `extern`$_{opt}$ `template` *declaration*

There are two forms of explicit instantiation: an explicit instantiation definition and an explicit instantiation declaration. An explicit instantiation declaration begins with the `extern` keyword.

1

If the explicit instantiation is for a class or member class, the *elaborated-type-specifier* in the *declaration* shall include a *simple-template-id*. If the explicit instantiation is for a function or member function, the *unqualified-*

id in the *declaration* shall be either a *template-id* or, where all template arguments can be deduced, a *template-name* or *operator-function-id*. [*Note:* The declaration may declare a *qualified-id*, in which case the *unqualified-id* of the *qualified-id* must be a *template-id*. — *end note*] If the explicit instantiation is for a member function, a member class or a static data member of a class template specialization, the name of the class template specialization in the *qualified-id* for the member name shall be a *simple-template-id*. If the explicit instantiation is for a variable, the *unqualified-id* in the declaration shall be a *template-id*. An explicit instantiation shall appear in an enclosing namespace of its template. If the name declared in the explicit instantiation is an unqualified name, the explicit instantiation shall appear in the namespace where its template is declared or, if that namespace is inline (7.1149.1), any namespace from its enclosing namespace set. [*Note:* Regarding qualified names in declarators, see 8.56. — *end note*] [*Example:*

```
template<class T> class Array { void mf(); };
template class Array<char>;
template void Array<int>::mf();

template<class T> void sort(Array<T>& v) { /* ... */ }
template void sort(Array<char>&);       // argument is deduced here

namespace N {
  template<class T> void f(T&) { }
}
template void N::f<int>(int&);
```

— *end example*]

1

A declaration of a function template, a variable template, a member function or static data member of a class template, or a member function template of a class or class template shall precede an explicit instantiation of that entity. A definition of a class template, a member class of a class template, or a member class template of a class or class template shall precede an explicit instantiation of that entity unless the explicit instantiation is preceded by an explicit specialization of the entity with the same template arguments. If the *declaration* of the explicit instantiation names an implicitly-declared special member function (Clause 12), the program is ill-formed.

1

For a given set of template arguments, if an explicit instantiation of a template appears after a declaration of an explicit specialization for that template, the explicit instantiation has no effect. Otherwise, for an explicit instantiation definition the definition of a function template, a variable template, a member function template, or a member function or static data member of a class template shall be present in every translation unit in which it is explicitly instantiated.

1

An explicit instantiation of a class, function template, or variable template specialization is placed in the namespace in which the template is defined. An explicit instantiation for a member of a class template is placed in the namespace where the enclosing class template is defined. An explicit instantiation for a member template is placed in the namespace where the enclosing class or class template is defined. [*Example:*

```
namespace N {
  template<class T> class Y { void mf() { } };
}

template class Y<int>;                  // error: class template Y not visible
                                        // in the global namespace

using N::Y;
```

```
template class Y<int>;                    // error: explicit instantiation outside of the
                                          // namespace of the template

template class N::Y<char*>;               // OK: explicit instantiation in namespace N
template void N::Y<double>::mf();         // OK: explicit instantiation
                                          // in namespace N
```

— *end example*]

1 A trailing *template-argument* can be left unspecified in an explicit instantiation of a function template specialization or of a member function template specialization provided it can be deduced from the type of a function parameter (14.2114.1). [*Example:*

```
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

// instantiate sort(Array<int>&) - template-argument deduced
template void sort<>(Array<int>&);
```

— *end example*]

2

An explicit instantiation that names a class template specialization is also an explicit instantiation of the same kind (declaration or definition) of each of its members (not including members inherited from base classes and members that are templates) that has not been previously explicitly specialized in the translation unit containing the explicit instantiation, except as described below. [*Note:* In addition, it will typically be an explicit instantiation of certain implementation-dependent data about the class. — *end note*]

1

An explicit instantiation definition that names a class template specialization explicitly instantiates the class template specialization and is an explicit instantiation definition of only those members that have been defined at the point of instantiation.

1

Except for inline functions, declarations with types deduced from their initializer or return value (7.832.0.1), `const` variables of literal types, variables of reference types, and class template specializations, explicit instantiation declarations have the effect of suppressing the implicit instantiation of the entity to which they refer. [*Note:* The intent is that an inline function that is the subject of an explicit instantiation declaration will still be implicitly instantiated when odr-used (3.91) so that the body can be considered for inlining, but that no out-of-line copy of the inline function would be generated in the translation unit. — *end note*]

1

If an entity is the subject of both an explicit instantiation declaration and an explicit instantiation definition in the same translation unit, the definition shall follow the declaration. An entity that is the subject of an explicit instantiation declaration and that is also used in a way that would otherwise cause an implicit instantiation (14.1644.1) in the translation unit shall be the subject of an explicit instantiation definition somewhere in the program; otherwise the program is ill-formed, no diagnostic required. [*Note:* This rule does apply to inline functions even though an explicit instantiation declaration of such an entity has no other normative effect. This is needed to ensure that if the address of an inline function is taken in a translation unit in which the implementation chose to suppress the out-of-line body, another translation unit will supply the body. — *end note*] An explicit instantiation declaration shall not name a specialization of a template with internal linkage.

1

The usual access checking rules do not apply to names used to specify explicit instantiations. [*Note:* In particular, the template arguments and names used in the function declarator (including parameter types, return types and exception specifications) may be private types or objects which would normally not be accessible and the template may be a member template or member function which would not normally be accessible. — *end note*]

1 An explicit instantiation does not constitute a use of a default argument, so default argument instantiation is not done. [*Example:*

```
char* p = 0;
template<class T> T g(T x = &p) { return x; }
template int g<int>(int);       // OK even though &p isn't an int.
```

— *end example*]

14.1921.1 Explicit specialization [temp.expl.spec]

1

An explicit specialization of any of the following:

— function template

— class template

— variable template

— member function of a class template

— static data member of a class template

— member class of a class template

— member enumeration of a class template

— member class template of a class or class template

— member function template of a class or class template

can be declared by a declaration introduced by `template<>`; that is:

explicit-specialization:
`template < >` *declaration*

[*Example:*

```
template<class T> class stream;

template<> class stream<char> { /* ... */ };

template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

template<> void sort<char*>(Array<char*>&) ;
```

Given these declarations, `stream<char>` will be used as the definition of streams of `char`s; other streams will be handled by class template specializations instantiated from the class template. Similarly, `sort<char*>` will be used as the sort function for arguments of type `Array<char*>`; other `Array` types will be sorted by functions generated from the template. — *end example*]

1

An explicit specialization shall be declared in a namespace enclosing the specialized template. An explicit specialization whose *declarator-id* is not qualified shall be declared in the nearest enclosing namespace of the template, or, if the namespace is inline (7.1149.1), any namespace from its enclosing namespace set. Such a declaration may also be a definition. If the declaration is not a definition, the specialization may be defined later (7.1215.0.1).

1

A declaration of a function template, class template, or variable template being explicitly specialized shall precede the declaration of the explicit specialization. [*Note:* A declaration, but not a definition of the template is required. — *end note*] The definition of a class or class template shall precede the declaration of an explicit specialization for a member template of the class or class template. [*Example:*

```
template<> class X<int> { /* ... */ };          // error: X not a template

template<class T> class X;

template<> class X<char*> { /* ... */ };        // OK: X is a template
```

— *end example*]

1

A member function, a member function template, a member class, a member enumeration, a member class template, a static data member, or a static data member template of a class template may be explicitly specialized for a class specialization that is implicitly instantiated; in this case, the definition of the class template shall precede the explicit specialization for the member of the class template. If such an explicit specialization for the member of a class template names an implicitly-declared special member function (Clause 12), the program is ill-formed.

1

A member of an explicitly specialized class is not implicitly instantiated from the member declaration of the class template; instead, the member of the class template specialization shall itself be explicitly defined if its definition is required. In this case, the definition of the class template explicit specialization shall be in scope at the point at which the member is defined. The definition of an explicitly specialized class is unrelated to the definition of a generated specialization. That is, its members need not have the same names, types, etc. as the members of a generated specialization. Members of an explicitly specialized class template are defined in the same manner as members of normal classes, and not using the `template<>` syntax. The same is true when defining a member of an explicitly specialized member class. However, `template<>` is used in defining a member of an explicitly specialized member class template that is specialized as a class template. [*Example:*

```
template<class T> struct A {
  struct B { };
  template<class U> struct C { };
};

template<> struct A<int> {
  void f(int);
};

void h() {
  A<int> a;
  a.f(16);          // A<int>::f must be defined somewhere
}

// template<> not used for a member of an
```

```
// explicitly specialized class template
void A<int>::f(int) { /* ... */ }

template<> struct A<char>::B {
  void f();
};
// template<> also not used when defining a member of
// an explicitly specialized member class
void A<char>::B::f() { /* ... */ }

template<> template<class U> struct A<char>::C {
  void f();
};
// template<> is used when defining a member of an explicitly
// specialized member class template specialized as a class template
template<>
template<class U> void A<char>::C<U>::f() { /* ... */ }

template<> struct A<short>::B {
  void f();
};
template<> void A<short>::B::f() { /* ... */ }  // error: template<> not permitted

template<> template<class U> struct A<short>::C {
  void f();
};
template<class U> void A<short>::C<U>::f() { /* ... */ }  // error: template<> required
```

— *end example*]

1

If a template, a member template or a member of a class template is explicitly specialized then that specialization shall be declared before the first use of that specialization that would cause an implicit instantiation to take place, in every translation unit in which such a use occurs; no diagnostic is required. If the program does not provide a definition for an explicit specialization and either the specialization is used in a way that would cause an implicit instantiation to take place or the member is a virtual member function, the program is ill-formed, no diagnostic required. An implicit instantiation is never generated for an explicit specialization that is declared but not defined. [*Example:*

```
class String { };
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

void f(Array<String>& v) {
  sort(v);          // use primary template
                    // sort(Array<T>&), T is String
}

template<> void sort<String>(Array<String>& v); // error: specialization
                                                // after use of primary template
template<> void sort<>(Array<char*>& v);        // OK: sort<char*> not yet used
template<class T> struct A {
  enum E : T;
  enum class S : T;
};
```

```
template<> enum A<int>::E : int { eint };          // OK
template<> enum class A<int>::S : int { sint };    // OK
template<class T> enum A<T>::E : T { eT };
template<class T> enum class A<T>::S : T { sT };
template<> enum A<char>::E : char { echar };        // ill-formed, A<char>::E was instantiated
                                                    // when A<char> was instantiated
template<> enum class A<char>::S : char { schar }; // OK
```

— *end example*]

1

The placement of explicit specialization declarations for function templates, class templates, variable templates, member functions of class templates, static data members of class templates, member classes of class templates, member enumerations of class templates, member class templates of class templates, member function templates of class templates, static data member templates of class templates, member functions of member templates of class templates, member functions of member templates of non-template classes, static data member templates of non-template classes, member function templates of member classes of class templates, etc., and the placement of partial specialization declarations of class templates, variable templates, member class templates of non-template classes, static data member templates of non-template classes, member class templates of class templates, etc., can affect whether a program is well-formed according to the relative positioning of the explicit specialization declarations and their points of instantiation in the translation unit as specified above and below. When writing a specialization, be careful about its location; or to make it compile will be such a trial as to kindle its self-immolation.

1

A template explicit specialization is in the scope of the namespace in which the template was defined. [*Example:*

```
namespace N {
  template<class T> class X { /* ... */ };
  template<class T> class Y { /* ... */ };

  template<> class X<int> { /* ... */ };          // OK: specialization
                                                  // in same namespace
  template<> class Y<double>;                     // forward declare intent to
                                                  // specialize for double
}

template<> class N::Y<double> { /* ... */ };      // OK: specialization
                                                  // in enclosing namespace
template<> class N::Y<short> { /* ... */ };       // OK: specialization
                                                  // in enclosing namespace
```

— *end example*]

1 A *simple-template-id* that names a class template explicit specialization that has been declared but not defined can be used exactly like the names of other incompletely-defined classes (3.2955). [*Example:*

```
template<class T> class X;      // X is a class template
template<> class X<int>;

X<int>* p;                      // OK: pointer to declared class X<int>
X<int> x;                       // error: object of incomplete class X<int>
```

— *end example*]

2

A trailing *template-argument* can be left unspecified in the *template-id* naming an explicit function template specialization provided it can be deduced from the function argument type. [*Example:*

```
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v);

// explicit specialization for sort(Array<int>&)
// with deduced template-argument of type int
template<> void sort(Array<int>&);
```

— *end example*]

1 A function with the same name as a template and a type that exactly matches that of a template specialization is not an explicit specialization (14.972.1).

2

An explicit specialization of a function template is inline only if it is declared with the `inline` specifier or defined as deleted, and independently of whether its function template is inline. [*Example:*

```
template<class T> void f(T) { /* ... */ }
template<class T> inline T g(T) { /* ... */ }

template<> inline void f<>(int) { /* ... */ }    // OK: inline
template<> int g<>(int) { /* ... */ }            // OK: not inline
```

— *end example*]

1

An explicit specialization of a static data member of a template or an explicit specialization of a static data member template is a definition if the declaration includes an initializer; otherwise, it is a declaration. [*Note:* The definition of a static data member of a template that requires default initialization must use a *braced-init-list*:

```
template<> X Q<int>::x;          // declaration
template<> X Q<int>::x ();       // error: declares a function
template<> X Q<int>::x { };      // definition
```

— *end note*]

1

A member or a member template of a class template may be explicitly specialized for a given implicit instantiation of the class template, even if the member or member template is defined in the class template definition. An explicit specialization of a member or member template is specified using the syntax for explicit specialization. [*Example:*

```
template<class T> struct A {
  void f(T);
  template<class X1> void g1(T, X1);
  template<class X2> void g2(T, X2);
  void h(T) { }
};

// specialization
template<> void A<int>::f(int);

// out of class member template definition
template<class T> template<class X1> void A<T>::g1(T, X1) { }
```

```
// member template specialization
template<> template<class X1> void A<int>::g1(int, X1);

//member template specialization
template<> template<>
  void A<int>::g1(int, char);           // X1 deduced as char
template<> template<>
  void A<int>::g2<char>(int, char);     // X2 specified as char

// member specialization even if defined in class definition
template<> void A<int>::h(int) { }
```

— *end example*]

1

A member or a member template may be nested within many enclosing class templates. In an explicit specialization for such a member, the member declaration shall be preceded by a `template<>` for each enclosing class template that is explicitly specialized. [*Example:*

```
template<class T1> class A {
  template<class T2> class B {
    void mf();
  };
};
template<> template<> class A<int>::B<double>;
template<> template<> void A<char>::B<char>::mf();
```

— *end example*]

1

In an explicit specialization declaration for a member of a class template or a member template that appears in namespace scope, the member template and some of its enclosing class templates may remain unspecialized, except that the declaration shall not explicitly specialize a class member template if its enclosing class templates are not explicitly specialized as well. In such explicit specialization declaration, the keyword `template` followed by a *template-parameter-list* shall be provided instead of the `template<>` preceding the explicit specialization declaration of the member. The types of the *template-parameters* in the *template-parameter-list* shall be the same as those specified in the primary template definition. [*Example:*

```
template <class T1> class A {
  template<class T2> class B {
    template<class T3> void mf1(T3);
    void mf2();
  };
};
template <> template <class X>
  class A<int>::B {
      template <class T> void mf1(T);
  };
template <> template <> template<class T>
  void A<int>::B<double>::mf1(T t) { }
template <class Y> template <>
  void A<Y>::B<double>::mf2() { }       // ill-formed; B<double> is specialized but
                                        // its enclosing class template A is not
```

— *end example*]

1 A specialization of a member function template, member class template, or static data member template of a non-specialized class template is itself a template.

2 An explicit specialization declaration shall not be a friend declaration.

3 Default function arguments shall not be specified in a declaration or a definition for one of the following explicit specializations:

(3.1) — the explicit specialization of a function template;

(3.2) — the explicit specialization of a member function template;

(3.3) — the explicit specialization of a member function of a class template where the class template specialization to which the member function specialization belongs is implicitly instantiated. [*Note:* Default function arguments may be specified in the declaration or definition of a member function of a class template specialization that is explicitly specialized. — *end note*]

14.2062 Function template specializations [temp.fct.spec]

1

A function instantiated from a function template is called a function template specialization; so is an explicit specialization of a function template. Template arguments can be explicitly specified when naming the function template specialization, deduced from the context (e.g., deduced from the function arguments in a call to the function template specialization, see 14.2114.1), or obtained from default template arguments.

1

Each function template specialization instantiated from a template has its own copy of any static variable. [*Example:*

```
template<class T> void f(T* p) {
  static T s;
};

void g(int a, char* b) {
  f(&a);            // calls f<int>(int*)
  f(&b);            // calls f<char*>(char**)
}
```

Here `f<int>(int*)` has a static variable `s` of type `int` and `f<char*>(char**)` has a static variable `s` of type `char*`. — *end example*]

14.2075.1 Explicit template argument specification [temp.arg.explicit]

1

Template arguments can be specified when referring to a function template specialization by qualifying the function template name with the list of *template-arguments* in the same way as *template-arguments* are specified in uses of a class template specialization. [*Example:*

```
template<class T> void sort(Array<T>& v);
void f(Array<dcomplex>& cv, Array<int>& ci) {
  sort<dcomplex>(cv);           // sort(Array<dcomplex>&)
  sort<int>(ci);                // sort(Array<int>&)
}
```

and

```
template<class U, class V> U convert(V v);
```

```
void g(double d) {
  int i = convert<int,double>(d);       // int convert(double)
  char c = convert<char,double>(d);     // char convert(double)
}
```

— *end example*]

1

A template argument list may be specified when referring to a specialization of a function template

— when a function is called,

— when the address of a function is taken, when a function initializes a reference to function, or when a pointer to member function is formed,

— in an explicit specialization,

— in an explicit instantiation, or

— in a friend declaration.

1

Trailing template arguments that can be deduced (14.2114.1) or obtained from default *template-argument*s may be omitted from the list of explicit *template-argument*s. A trailing template parameter pack (14.703.1) not otherwise deduced will be deduced to an empty sequence of template arguments. If all of the template arguments can be deduced, they may all be omitted; in this case, the empty template argument list `<>` itself may also be omitted. In contexts where deduction is done and fails, or in contexts where deduction is not done, if a template argument list is specified and it, along with any default template arguments, identifies a single function template specialization, then the *template-id* is an lvalue for the function template specialization. [*Example:*

```
template<class X, class Y> X f(Y);
template<class X, class Y, class ... Z> X g(Y);
void h() {
  int i = f<int>(5.6);          // Y is deduced to be double
  int j = f(5.6);               // ill-formed: X cannot be deduced
  f<void>(f<int, bool>);        // Y for outer f deduced to be
                                // int (*)(bool)
  f<void>(f<int>);              // ill-formed: f<int> does not denote a
                                // single function template specialization
  int k = g<int>(5.6);          // Y is deduced to be double, Z is deduced to an empty sequence
  f<void>(g<int, bool>);        // Y for outer f is deduced to be
                                // int (*)(bool), Z is deduced to an empty sequence
}
```

— *end example*]

1

[*Note:* An empty template argument list can be used to indicate that a given use refers to a specialization of a function template even when a non-template function (8.360.1) is visible that would otherwise be used. For example:

```
template <class T> int f(T);    // #1
int f(int);                     // #2
int k = f(1);                   // uses #2
int l = f<>(1);                 // uses #1
```

— *end note*]

1 Template arguments that are present shall be specified in the declaration order of their corresponding *template-parameter*s. The template argument list shall not specify more *template-argument*s than there are corresponding *template-parameter*s unless one of the *template-parameter*s is a template parameter pack. [*Example:*

```
template<class X, class Y, class Z> X f(Y,Z);
template<class ... Args> void f2();
void g() {
  f<int,const char*,double>("aa",3.0);
  f<int,const char*>("aa",3.0);        // Z is deduced to be double
  f<int>("aa",3.0);                // Y is deduced to be const char*, and
                                   // Z is deduced to be double
  f("aa",3.0);                     // error: X cannot be deduced
  f2<char, short, int, long>(); // OK
}
```

— *end example*]

2

Implicit conversions (Clause 4) will be performed on a function argument to convert it to the type of the corresponding function parameter if the parameter type contains no *template-parameter*s that participate in template argument deduction. [*Note:* Template parameters do not participate in template argument deduction if they are explicitly specified. For example,

```
template<class T> void f(T);

class Complex {
  Complex(double);
};

void g() {
  f<Complex>(1);                   // OK, means f<Complex>(Complex(1))
}
```

— *end note*]

1 [*Note:* Because the explicit template argument list follows the function template name, and because conversion member function templates and constructor member function templates are called without using a function name, there is no way to provide an explicit template argument list for these function templates. — *end note*]

2

[*Note:* For simple function names, argument dependent lookup (3.1092.1) applies even when the function name is not visible within the scope of the call. This is because the call still has the syntactic form of a function call (3.952.1). But when a function template with explicit template arguments is used, the call does not have the correct syntactic form unless there is a function template with that name visible at the point of the call. If no such name is visible, the call is not syntactically well-formed and argument-dependent lookup does not apply. If some such name is visible, argument dependent lookup applies and additional function templates may be found in other namespaces. [*Example:*

```
namespace A {
  struct B { };
  template<int X> void f(B);
}
namespace C {
```

```
  template<class T> void f(T t);
}
void g(A::B b) {
  f<3>(b);                      // ill-formed: not a function call
  A::f<3>(b);                   // well-formed
  C::f<3>(b);                   // ill-formed; argument dependent lookup
                                // applies only to unqualified names
  using C::f;
  f<3>(b);                      // well-formed because C::f is visible; then
                                // A::f is found by argument dependent lookup
}
```

— *end example*] — *end note*]

1

Template argument deduction can extend the sequence of template arguments corresponding to a template parameter pack, even when the sequence contains explicitly specified template arguments. [*Example:*

```
template<class ... Types> void f(Types ... values);

void g() {
  f<int*, float*>(0, 0, 0);     // Types is deduced to the sequence int*, float*, int
}
```

— *end example*]

14.2114.1 Template argument deduction [temp.deduct]

1

When a function template specialization is referenced, all of the template arguments shall have values. The values can be explicitly specified or, in some cases, be deduced from the use or obtained from default *template-arguments*. [*Example:*

```
void f(Array<dcomplex>& cv, Array<int>& ci) {
  sort(cv);                     // calls sort(Array<dcomplex>&)
  sort(ci);                     // calls sort(Array<int>&)
}
```

and

```
void g(double d) {
  int i = convert<int>(d);      // calls convert<int,double>(double)
  int c = convert<char>(d);     // calls convert<char,double>(double)
}
```

— *end example*]

1

When an explicit template argument list is specified, the template arguments must be compatible with the template parameter list and must result in a valid function type as described below; otherwise type deduction fails. Specifically, the following steps are performed when evaluating an explicitly specified template argument list with respect to a given function template:

— The specified template arguments must match the template parameters in kind (i.e., type, non-type, template). There must not be more arguments than there are parameters unless at least one parameter is a template parameter pack, and there shall be an argument for each non-pack parameter. Otherwise, type deduction fails.

— Non-type arguments must match the types of the corresponding non-type template parameters, or must be convertible to the types of the corresponding non-type parameters as specified in 14.364.1, otherwise type deduction fails.

— The specified template argument values are substituted for the corresponding template parameters as specified below.

1

After this substitution is performed, the function parameter type adjustments described in 8.360.1 are performed. [*Example:* A parameter type of "`void ()(const int, int[5])`" becomes "`void(*)(int,int*)`". — *end example*] [*Note:* A top-level qualifier in a function parameter declaration does not affect the function type but still affects the type of the function parameter variable within the function. — *end note*] [*Example:*

```
template <class T> void f(T t);
template <class X> void g(const X x);
template <class Z> void h(Z, Z*);

int main() {
  // #1: function type is f(int), t is non const
  f<int>(1);

  // #2: function type is f(int), t is const
  f<const int>(1);

  // #3: function type is g(int), x is const
  g<int>(1);

  // #4: function type is g(int), x is const
  g<const int>(1);

  // #5: function type is h(int, const int*)
  h<const int>(1,0);
}
```

— *end example*]

1

[*Note:* `f<int>(1)` and `f<const int>(1)` call distinct functions even though both of the functions called have the same function type. — *end note*]

1

The resulting substituted and adjusted function type is used as the type of the function template for template argument deduction. If a template argument has not been deduced and its corresponding template parameter has a default argument, the template argument is determined by substituting the template arguments determined for preceding template parameters into the default argument. If the substitution results in an invalid type, as described above, type deduction fails. [*Example:*

```
template <class T, class U = double>
void f(T t = 0, U u = 0);

void g() {
  f(1, 'c');        // f<int,char>(1,'c')
  f(1);             // f<int,double>(1,0)
  f();              // error: T cannot be deduced
  f<int>();         // f<int,double>(0,0)
  f<int,char>();    // f<int,char>(0,0)
```

```
}
```

— *end example*]

When all template arguments have been deduced or obtained from default template arguments, all uses of template parameters in the template parameter list of the template and the function type are replaced with the corresponding deduced or default argument values. If the substitution results in an invalid type, as described above, type deduction fails.

1

At certain points in the template argument deduction process it is necessary to take a function type that makes use of template parameters and replace those template parameters with the corresponding template arguments. This is done at the beginning of template argument deduction when any explicitly specified template arguments are substituted into the function type, and again at the end of template argument deduction when any template arguments that were deduced or obtained from default arguments are substituted.

1

The substitution occurs in all types and expressions that are used in the function type and in template parameter declarations. The expressions include not only constant expressions such as those that appear in array bounds or as nontype template arguments but also general expressions (i.e., non-constant expressions) inside `sizeof`, `decltype`, and other contexts that allow non-constant expressions. The substitution proceeds in lexical order and stops when a condition that causes deduction to fail is encountered. [*Note:* The equivalent substitution in exception specifications is done only when the *exception-specification* is instantiated, at which point a program is ill-formed if the substitution results in an invalid type or expression. — *end note*] [*Example:*

```
template <class T> struct A { using X = typename T::X; };
template <class T> typename T::X f(typename A<T>::X);
template <class T> void f(...) { }
template <class T> auto g(typename A<T>::X) -> typename T::X;
template <class T> void g(...) { }

void h() {
  f<int>(0); // OK, substituting return type causes deduction to fail
  g<int>(0); // error, substituting parameter type instantiates A<int>
}
```

— *end example*]

1

If a substitution results in an invalid type or expression, type deduction fails. An invalid type or expression is one that would be ill-formed, with a diagnostic required, if written using the substituted arguments. [*Note:* If no diagnostic is required, the program is still ill-formed. Access checking is done as part of the substitution process. — *end note*] Only invalid types and expressions in the immediate context of the function type and its template parameter types can result in a deduction failure. [*Note:* The evaluation of the substituted types and expressions can result in side effects such as the instantiation of class template specializations and/or function template specializations, the generation of implicitly-defined functions, etc. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]

[*Example:*

```
struct X { };
struct Y {
  Y(X){}
};
```

```
template <class T> auto f(T t1, T t2) -> decltype(t1 + t2); // #1
X f(Y, Y);  // #2

X x1, x2;
X x3 = f(x1, x2);  // deduction fails on #1 (cannot add X+X), calls #2
```

— *end example*]

[*Note:* Type deduction may fail for the following reasons:

— Attempting to instantiate a pack expansion containing multiple parameter packs of differing lengths.

— Attempting to create an array with an element type that is `void`, a function type, a reference type, or an abstract class type, or attempting to create an array with a size that is zero or negative. [*Example:*

```
template <class T> int f(T[5]);
int I = f<int>(0);
int j = f<void>(0);              // invalid array
```

— *end example*]

— Attempting to use a type that is not a class or enumeration type in a qualified name. [*Example:*

```
template <class T> int f(typename T::B*);
int i = f<int>(0);
```

— *end example*]

— Attempting to use a type in a *nested-name-specifier* of a *qualified-id* when that type does not contain the specified member, or

  — the specified member is not a type where a type is required, or

  — the specified member is not a template where a template is required, or

  — the specified member is not a non-type where a non-type is required.

[*Example:*

```
template <int I> struct X { };
template <template <class T> class> struct Z { };
template <class T> void f(typename T::Y*){}
template <class T> void g(X<T::N>*){}
template <class T> void h(Z<T::template TT>*){}
struct A {};
struct B { int Y; };
struct C {
  typedef int N;
};
struct D {
  typedef int TT;
};

int main() {
  // Deduction fails in each of these cases:
  f<A>(0);  // A does not contain a member Y
  f<B>(0);  // The Y member of B is not a type
  g<C>(0);  // The N member of C is not a non-type
  h<D>(0);  // The TT member of D is not a template
}
```

— *end example*]

— Attempting to create a pointer to reference type.

— Attempting to create a reference to `void`.

— Attempting to create "pointer to member of `T`" when `T` is not a class type. [*Example:*

```
template <class T> int f(int T::*);
int i = f<int>(0);
```

— *end example*]

— Attempting to give an invalid type to a non-type template parameter. [*Example:*

```
template <class T, T> struct S {};
template <class T> int f(S<T, T()>*);
struct X {};
int i0 = f<X>(0);
```

— *end example*]

— Attempting to perform an invalid conversion in either a template argument expression, or an expression used in the function declaration. [*Example:*

```
template <class T, T*> int f(int);
int i2 = f<int,1>(0);          // can't conv 1 to int*
```

— *end example*]

— Attempting to create a function type in which a parameter has a type of `void`, or in which the return type is a function type or array type.

— Attempting to create a function type in which a parameter type or the return type is an abstract class type (10.276).

— *end note*]

1

Except as described above, the use of an invalid value shall not cause type deduction to fail. [*Example:* In the following example 1000 is converted to `signed char` and results in an implementation-defined value as specified in (4.397). In other words, both templates are considered even though 1000, when converted to `signed char`, results in an implementation-defined value.

```
template <int> int f(int);
template <signed char> int f(int);
int i1 = f<1>(0);              // ambiguous
int i2 = f<1000>(0);           // ambiguous
```

— *end example*]

14.2261.0.1 Deducing template arguments from a function call [temp.deduct.call]

1

Template argument deduction is done by comparing each function template parameter type (call it `P`) with the type of the corresponding argument of the call (call it `A`) as described below. If removing references and cv-qualifiers from `P` gives `std::initializer_list<`P'`>` for some P' and the argument is an initializer list (8.2435.1), then deduction is performed instead for each element of the initializer list, taking P' as a function template parameter type and the initializer element as its argument. Otherwise, an initializer list argument causes the parameter to be considered a non-deduced context (14.2492.0.1). [*Example:*

```
template<class T> void f(std::initializer_list<T>);
f({1,2,3});                 // T deduced to int
f({1,"asdf"});              // error: T deduced to both int and const char*

template<class T> void g(T);
g({1,2,3});                 // error: no argument deduced for T
```

— *end example*] For a function parameter pack that occurs at the end of the *parameter-declaration-list*, the type `A` of each remaining argument of the call is compared with the type `P` of the *declarator-id* of the function parameter pack. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. When a function parameter pack appears in a non-deduced context (14.2492.0.1), the type of that parameter pack is never deduced. [*Example:*

```
template<class ... Types> void f(Types& ...);
template<class T1, class ... Types> void g(T1, Types ...);
template<class T1, class ... Types> void g1(Types ..., T1);

void h(int x, float& y) {
  const int z = x;
  f(x, y, z);                  // Types is deduced to int, float, const int
  g(x, y, z);                  // T1 is deduced to int; Types is deduced to float, int
  g1(x, y, z);                 // error: Types is not deduced
  g1<int, int, int>(x, y, z);  // OK, no deduction occurs

}
```

— *end example*]

1

If `P` is not a reference type:

— If `A` is an array type, the pointer type produced by the array-to-pointer standard conversion (4.180) is used in place of `A` for type deduction; otherwise,

— If `A` is a function type, the pointer type produced by the function-to-pointer standard conversion (4.220) is used in place of `A` for type deduction; otherwise,

— If `A` is a cv-qualified type, the top level cv-qualifiers of `A`'s type are ignored for type deduction.

1

If `P` is a cv-qualified type, the top level cv-qualifiers of `P`'s type are ignored for type deduction. If `P` is a reference type, the type referred to by `P` is used for type deduction. If `P` is an rvalue reference to a cv-unqualified template parameter and the argument is an lvalue, the type "lvalue reference to `A`" is used in place of `A` for type deduction. [*Example:*

```
template <class T> int f(T&&);
template <class T> int g(const T&&);
int i;
int n1 = f(i);                  // calls f<int&>(int&)
int n2 = f(0);                  // calls f<int>(int&&)
int n3 = g(i);                  // error: would call g<int>(const int&&), which
                                // would bind an rvalue reference to an lvalue
```

— *end example*]

1

In general, the deduction process attempts to find template argument values that will make the deduced `A` identical to `A` (after the type `A` is transformed as described above). However, there are three cases that allow a difference:

— If the original `P` is a reference type, the deduced `A` (i.e., the type referred to by the reference) can be more cv-qualified than the transformed `A`.

— The transformed `A` can be another pointer or pointer to member type that can be converted to the deduced `A` via a qualification conversion (4.246).

— If `P` is a class and `P` has the form *simple-template-id*, then the transformed `A` can be a derived class of the deduced `A`. Likewise, if `P` is a pointer to a class of the form *simple-template-id*, the transformed `A` can be a pointer to a derived class pointed to by the deduced `A`.

[*Note:* as specified in 14.2075.1, implicit conversions will be performed on a function argument to convert it to the type of the corresponding function parameter if the parameter contains no *template-parameter*s that participate in template argument deduction. Such conversions are also allowed, in addition to the ones described in the preceding list. — *end note*]

1

These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced `A`, the type deduction fails. [*Note:* If a *template-parameter* is not used in any of the function parameters of a function template, or is used only in a non-deduced context, its corresponding *template-argument* cannot be deduced from a function call and the *template-argument* must be explicitly specified. — *end note*]

1

When P is a function type, pointer to function type, or pointer to member function type:

— If the argument is an overload set containing one or more function templates, the parameter is treated as a non-deduced context.

— If the argument is an overload set (not containing function templates), trial argument deduction is attempted using each of the members of the set. If deduction succeeds for only one of the overload set members, that member is used as the argument value for the deduction. If deduction succeeds for more than one member of the overload set the parameter is treated as a non-deduced context.

1 [*Example:*

```
// Only one function of an overload set matches the call so the function
// parameter is a deduced context.
template <class T> int f(T (*p)(T));
int g(int);
int g(char);
int i = f(g);        // calls f(int (*)(int))
```

— *end example*]

2 [*Example:*

```
// Ambiguous deduction causes the second function parameter to be a
// non-deduced context.
template <class T> int f(T, T (*p)(T));
int g(int);
char g(char);
int i = f(1, g);     // calls f(int, int (*)(int))
```

— *end example*]

3 [*Example:*

```
// The overload set contains a template, causing the second function
// parameter to be a non-deduced context.
template <class T> int f(T, T (*p)(T));
char g(char);
template <class T> T g(T);
int i = f(1, g);     // calls f(int, int (*)(int))
```

— *end example*]

14.2407.0.1 Deducing template arguments taking the address of a function template [temp.deduct.funcaddr]

1

Template arguments can be deduced from the type specified when taking the address of an overloaded function (13.1084). The function template's function type and the specified type are used as the types of `P` and `A`, and the deduction is done as described in 14.2492.0.1.

1

A placeholder type (7.832.0.1) in the return type of a function template is a non-deduced context. If template argument deduction succeeds for such a function, the return type is determined from instantiation of the function body.

14.2413.0.1 Deducing conversion function template arguments [temp.deduct.conv]

1

Template argument deduction is done by comparing the return type of the conversion function template (call it `P`) with the type that is required as the result of the conversion (call it `A`; see 8.821, 13.396.0.1, and 13.413.0.1 for the determination of that type) as described in 14.2492.0.1.

1

If `P` is a reference type, the type referred to by `P` is used in place of `P` for type deduction and for any further references to or transformations of `P` in the remainder of this section.

1 If `A` is not a reference type:

(1.1) — If `P` is an array type, the pointer type produced by the array-to-pointer standard conversion (4.180) is used in place of `P` for type deduction; otherwise,

(1.2) — If `P` is a function type, the pointer type produced by the function-to-pointer standard conversion (4.220) is used in place of `P` for type deduction; otherwise,

(1.3) — If `P` is a cv-qualified type, the top level cv-qualifiers of `P`'s type are ignored for type deduction.

2 If `A` is a cv-qualified type, the top level cv-qualifiers of `A`'s type are ignored for type deduction. If `A` is a reference type, the type referred to by `A` is used for type deduction.

3

In general, the deduction process attempts to find template argument values that will make the deduced `A` identical to `A`. However, there are two cases that allow a difference:

— If the original `A` is a reference type, `A` can be more cv-qualified than the deduced `A` (i.e., the type referred to by the reference)

— The deduced `A` can be another pointer or pointer to member type that can be converted to `A` via a qualification conversion.

1 These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced `A`, the type deduction fails.

2 When the deduction process requires a qualification conversion for a pointer or pointer to member type as described above, the following process is used to determine the deduced template argument values:

If `A` is a type

$$cv_{1,0} \text{ “pointer to ...” } cv_{1,n-1} \text{ “pointer to” } cv_{1,n}\, T1$$

and `P` is a type

$$cv_{2,0} \text{ “pointer to ...” } cv_{2,n-1} \text{ “pointer to” } cv_{2,n}\, T2$$

The cv-unqualified `T1` and `T2` are used as the types of `A` and `P` respectively for type deduction. [*Example:*

```
struct A {
  template <class T> operator T***();
};
A a;
const int * const * const * p1 = a;      // T is deduced as int, not const int
```

— *end example*]

14.2418.0.1 Deducing template arguments during partial ordering [temp.deduct.partial]

1 Template argument deduction is done by comparing certain types associated with the two function templates being compared.

2

Two sets of types are used to determine the partial ordering. For each of the templates involved there is the original function type and the transformed function type. [*Note:* The creation of the transformed type is described in 14.992.0.1. — *end note*] The deduction process uses the transformed type as the argument template and the original type of the other template as the parameter template. This process is done twice for each type involved in the partial ordering comparison: once using the transformed template-1 as the argument template and template-2 as the parameter template and again using the transformed template-2 as the argument template and template-1 as the parameter template.

1

The types used to determine the ordering depend on the context in which the partial ordering is done:

— In the context of a function call, the types used are those function parameter types for which the function call has arguments.[143]

— In the context of a call to a conversion function, the return types of the conversion function templates are used.

— In other contexts (14.992.0.1) the function template's function type is used.

1

Each type nominated above from the parameter template and the corresponding type from the argument template are used as the types of `P` and `A`.

1

143) Default arguments are not considered to be arguments in this context; they only become arguments after a function has been selected.

Before the partial ordering is done, certain transformations are performed on the types used for partial ordering:

— If `P` is a reference type, `P` is replaced by the type referred to.

— If `A` is a reference type, `A` is replaced by the type referred to.

1

If both `P` and `A` were reference types (before being replaced with the type referred to above), determine which of the two types (if any) is more cv-qualified than the other; otherwise the types are considered to be equally cv-qualified for partial ordering purposes. The result of this determination will be used below.

1 Remove any top-level cv-qualifiers:

(1.1) — If `P` is a cv-qualified type, `P` is replaced by the cv-unqualified version of `P`.

(1.2) — If `A` is a cv-qualified type, `A` is replaced by the cv-unqualified version of `A`.

2

If `A` was transformed from a function parameter pack and `P` is not a parameter pack, type deduction fails. Otherwise, using the resulting types `P` and `A`, the deduction is then done as described in 14.2492.0.1. If `P` is a function parameter pack, the type `A` of each remaining parameter type of the argument template is compared with the type `P` of the *declarator-id* of the function parameter pack. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. If deduction succeeds for a given type, the type from the argument template is considered to be at least as specialized as the type from the parameter template. [*Example:*

```
template<class... Args>           void f(Args... args);           // #1
template<class T1, class... Args> void f(T1 a1, Args... args);    // #2
template<class T1, class T2>      void f(T1 a1, T2 a2);           // #3

f();                  // calls #1
f(1, 2, 3);           // calls #2
f(1, 2);              // calls #3; non-variadic template #3 is more
                      // specialized than the variadic templates #1 and #2
```

— *end example*]

1

If, for a given type, deduction succeeds in both directions (i.e., the types are identical after the transformations above) and both `P` and `A` were reference types (before being replaced with the type referred to above):

— if the type from the argument template was an lvalue reference and the type from the parameter template was not, the argument type is considered to be more specialized than the other; otherwise,

— if the type from the argument template is more cv-qualified than the type from the parameter template (as described above), the argument type is considered to be more specialized than the other; otherwise,

— neither type is more specialized than the other.

1

If for each type being considered a given template is at least as specialized for all types and more specialized for some set of types and the other template is not more specialized for any types or is not at least as specialized for any types, then the given template is more specialized than the other template. Otherwise, neither template is more specialized than the other.

1

In most cases, all template parameters must have values in order for deduction to succeed, but for partial ordering purposes a template parameter may remain without a value provided it is not used in the types being used for partial ordering. [*Note:* A template parameter used in a non-deduced context is considered used. — *end note*] [*Example:*

```
template <class T> T f(int);        // #1
template <class T, class U> T f(U); // #2
void g() {
  f<int>(1);        // calls #1
}
```

— *end example*]

1

[*Note:* Partial ordering of function templates containing template parameter packs is independent of the number of deduced arguments for those template parameter packs. — *end note*] [*Example:*

```
template<class ...> struct Tuple { };
template<class ... Types> void g(Tuple<Types ...>);                  // #1
template<class T1, class ... Types> void g(Tuple<T1, Types ...>);    // #2
template<class T1, class ... Types> void g(Tuple<T1, Types& ...>);   // #3

g(Tuple<>());                   // calls #1
g(Tuple<int, float>());         // calls #2
g(Tuple<int, float&>());        // calls #3
g(Tuple<int>());                // calls #3
```

— *end example*]

14.2492.0.1 Deducing template arguments from a type [temp.deduct.type]

1

Template arguments can be deduced in several different contexts, but in each case a type that is specified in terms of template parameters (call it `P`) is compared with an actual type (call it `A`), and an attempt is made to find template argument values (a type for a type parameter, a value for a non-type parameter, or a template for a template parameter) that will make `P`, after substitution of the deduced values (call it the deduced `A`), compatible with `A`.

1

In some cases, the deduction is done using a single set of types `P` and `A`, in other cases, there will be a set of corresponding types `P` and `A`. Type deduction is done independently for each `P/A` pair, and the deduced template argument values are then combined. If type deduction cannot be done for any `P/A` pair, or if for any pair the deduction leads to more than one possible set of deduced values, or if different pairs yield different deduced values, or if any template argument remains neither deduced nor explicitly specified, template argument deduction fails.

1 A given type `P` can be composed from a number of other types, templates, and non-type values:

(1.1) — A function type includes the types of each of the function parameters and the return type.

(1.2) — A pointer to member type includes the type of the class object pointed to and the type of the member pointed to.

(1.3) — A type that is a specialization of a class template (e.g., `A<int>`) includes the types, templates, and non-type values referenced by the template argument list of the specialization.

(1.4) — An array type includes the array element type and the value of the array bound.

2

In most cases, the types, templates, and non-type values that are used to compose `P` participate in template argument deduction. That is, they may be used to determine the value of a template argument, and the value so determined must be consistent with the values determined elsewhere. In certain contexts, however, the value does not participate in type deduction, but instead uses the values of template arguments that were either deduced elsewhere or explicitly specified. If a template parameter is used only in non-deduced contexts and is not explicitly specified, template argument deduction fails.

1

The non-deduced contexts are:

— The *nested-name-specifier* of a type that was specified using a *qualified-id*.

— The *expression* of a *decltype-specifier*.

— A non-type template argument or an array bound in which a subexpression references a template parameter.

— A template parameter used in the parameter type of a function parameter that has a default argument that is being used in the call for which argument deduction is being done.

— A function parameter for which argument deduction cannot be done because the associated function argument is a function, or a set of overloaded functions (13.1084), and one or more of the following apply:

  — more than one function matches the function parameter type (resulting in an ambiguous deduction), or

  — no function matches the function parameter type, or

  — the set of functions supplied as an argument contains one or more function templates.

— A function parameter for which the associated argument is an initializer list (8.2435.1) but the parameter does not have `std::initializer_list` or reference to possibly cv-qualified `std::initializer_list` type. [*Example:*

```
template<class T> void g(T);
g({1,2,3});                 // error: no argument deduced for T
```

— *end example*]

— A function parameter pack that does not occur at the end of the *parameter-declaration-list*.

1

When a type name is specified in a way that includes a non-deduced context, all of the types that comprise that type name are also non-deduced. However, a compound type can include both deduced and non-deduced types. [*Example:* If a type is specified as `A<T>::B<T2>`, both `T` and `T2` are non-deduced. Likewise, if a type is specified as `A<I+J>::X<T>`, `I`, `J`, and `T` are non-deduced. If a type is specified as `void f(typename A<T>::B, A<T>)`, the `T` in `A<T>::B` is non-deduced but the `T` in `A<T>` is deduced. — *end example*]

1 [*Example:* Here is an example in which different parameter/argument pairs produce inconsistent template argument deductions:

```
template<class T> void f(T x, T y) { /* ... */ }
struct A { /* ... */ };
struct B : A { /* ... */ };
void g(A a, B b) {
  f(a,b);           // error: T could be A or B
  f(b,a);           // error: T could be A or B
  f(a,a);           // OK: T is A
  f(b,b);           // OK: T is B
}
```

Here is an example where two template arguments are deduced from a single function parameter/argument pair. This can lead to conflicts that cause type deduction to fail:

```
template <class T, class U> void f(  T (*)( T, U, U )  );

int g1( int, float, float);
char g2( int, float, float);
int g3( int, char, float);

void r() {
  f(g1);            // OK: T is int and U is float
  f(g2);            // error: T could be char or int
  f(g3);            // error: U could be char or float
}
```

Here is an example where a qualification conversion applies between the argument type on the function call and the deduced template argument type:

```
template<class T> void f(const T*) { }
int* p;
void s() {
  f(p);             // f(const int*)
}
```

Here is an example where the template argument is used to instantiate a derived class type of the corresponding function parameter type:

```
template <class T> struct B { };
template <class T> struct D : public B<T> {};
struct D2 : public B<int> {};
template <class T> void f(B<T>&){}
void t() {
  D<int> d;
  D2     d2;
  f(d);             // calls f(B<int>&)
  f(d2);            // calls f(B<int>&)
}
```

— *end example*]

2

A template type argument `T`, a template template argument `TT` or a template non-type argument `i` can be deduced if `P` and `A` have one of the following forms:

```
T
cv-list T
T*
```

```
T&
T&&
T[integer-constant]
template-name<T>  (where template-name refers to a class template)
type(T)
T()
T(T)
T type::*
type T::*
T T::*
T (type::*)()
type (T::*)()
type (type::*)(T)
type (T::*)(T)
T (type::*)(T)
T (T::*)()
T (T::*)(T)
type[i]
template-name<i>  (where template-name refers to a class template)
TT<T>
TT<i>
TT<>
```

where `(T)` represents a *parameter-type-list* where at least one parameter type contains a `T`, and `()` represents a *parameter-type-list* where no parameter type contains a `T`. Similarly, `<T>` represents template argument lists where at least one argument contains a `T`, `<i>` represents template argument lists where at least one argument contains an `i` and `<>` represents template argument lists where no argument contains a `T` or an `i`.

1

If `P` has a form that contains `<T>` or `<i>`, then each argument $\mathtt{P}_i$ of the respective template argument list `P` is compared with the corresponding argument $\mathtt{A}_i$ of the corresponding template argument list of `A`. If the template argument list of `P` contains a pack expansion that is not the last template argument, the entire template argument list is a non-deduced context. If $\mathtt{P}_i$ is a pack expansion, then the pattern of $\mathtt{P}_i$ is compared with each remaining argument in the template argument list of `A`. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by $\mathtt{P}_i$. During partial ordering (14.2418.0.1), if $\mathtt{A}_i$ was originally a pack expansion:

— if `P` does not contain a template argument corresponding to $\mathtt{A}_i$ then $\mathtt{A}_i$ is ignored;

— otherwise, if $\mathtt{P}_i$ is not a pack expansion, template argument deduction fails.

[*Example:*

```
template<class T1, class... Z> class S;                              // #1
template<class T1, class... Z> class S<T1, const Z&...> { };         // #2
template<class T1, class T2>   class S<T1, const T2&> { };           // #3
S<int, const int&> s;         // both #2 and #3 match; #3 is more specialized

template<class T, class... U>            struct A { };               // #1
template<class T1, class T2, class... U> struct A<T1, T2*, U...> { }; // #2
template<class T1, class T2>             struct A<T1, T2> { };       // #3
template struct A<int, int*>; // selects #2
```

— *end example*]

1

Similarly, if P has a form that contains (T), then each parameter type P_i of the respective *parameter-type-list* of P is compared with the corresponding parameter type A_i of the corresponding *parameter-type-list* of A. If P and A are function types that originated from deduction when taking the address of a function template (14.2407.0.1) or when deducing template arguments from a function declaration (14.2655.0.1) and P_i and A_i are parameters of the top-level *parameter-type-list* of P and A, respectively, P_i is adjusted if it is an rvalue reference to a cv-unqualified template parameter and A_i is an lvalue reference, in which case the type of P_i is changed to be the template parameter type (i.e., T&& is changed to simply T). [*Note:* As a result, when P_i is T&& and A_i is X&, the adjusted P_i will be T, causing T to be deduced as X&. — *end note*]
[*Example:*

```
template <class T> void f(T&&);
template <> void f(int&) { }  // #1
template <> void f(int&&) { } // #2
void g(int i) {
  f(i);                       // calls f<int&>(int&), i.e., #1
  f(0);                       // calls f<int>(int&&), i.e., #2
}
```

— *end example*]

If the *parameter-declaration* corresponding to P_i is a function parameter pack, then the type of its *declarator-id* is compared with each remaining parameter type in the *parameter-type-list* of A. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. During partial ordering (14.2418.0.1), if A_i was originally a function parameter pack:

— if P does not contain a function parameter type corresponding to A_i then A_i is ignored;

— otherwise, if P_i is not a function parameter pack, template argument deduction fails.

[*Example:*

```
template<class T, class... U> void f(T*, U...) { }    // #1
template<class T>             void f(T) { }           // #2
template void f(int*);      // selects #1
```

— *end example*]

1 These forms can be used in the same way as T is for further composition of types. [*Example:*

```
X<int> (*)(char[6])
```

is of the form

```
template-name<T> (*)(type[i])
```

which is a variant of

```
type (*)(T)
```

where type is X<int> and T is char[6]. — *end example*]

2 Template arguments cannot be deduced from function arguments involving constructs other than the ones specified above.

3

A template type argument cannot be deduced from the type of a non-type *template-argument*.

1 [*Example:*

```
template<class T, T i> void f(double a[10][i]);
int v[10][20];
f(v);                // error: argument for template-parameter T cannot be deduced
```

— *end example*]

2 [*Note:* Except for reference and pointer types, a major array bound is not part of a function parameter type and cannot be deduced from an argument:

```
template<int i> void f1(int a[10][i]);
template<int i> void f2(int a[i][20]);
template<int i> void f3(int (&a)[i][20]);

void g() {
  int v[10][20];
  f1(v);             // OK: i deduced to be 20
  f1<20>(v);         // OK
  f2(v);             // error: cannot deduce template-argument i
  f2<10>(v);         // OK
  f3(v);             // OK: i deduced to be 10
}
```

3

If, in the declaration of a function template with a non-type template parameter, the non-type template parameter is used in a subexpression in the function parameter list, the expression is a non-deduced context as specified above. [*Example:*

```
template <int i> class A { /* ... */ };
template <int i> void g(A<i+1>);
template <int i> void f(A<i>, A<i+1>);
void k() {
  A<1> a1;
  A<2> a2;
  g(a1);             // error: deduction fails for expression i+1
  g<0>(a1);          // OK
  f(a1, a2);         // OK
}
```

— *end example*] — *end note*] [*Note:* Template parameters do not participate in template argument deduction if they are used only in non-deduced contexts. For example,

```
template<int i, typename T>
T deduce(typename A<T>::X x,     // T is not deduced here
  T t,                           // but T is deduced here
  typename B<i>::Y y);           // i is not deduced here
A<int> a;
B<77>  b;

int    x = deduce<77>(a.xm, 62, b.ym);
// T is deduced to be int, a.xm must be convertible to
// A<int>::X
// i is explicitly specified to be 77, b.ym must be convertible
// to B<77>::Y
```

— *end note*]

1

If `P` has a form that contains `<i>`, and if the type of the corresponding value of `A` differs from the type of `i`, deduction fails. If `P` has a form that contains `[i]`, and if the type of `i` is not an integral type, deduction fails.[144] [*Example:*

```
template<int i> class A { /* ... */ };
template<short s> void f(A<s>);
void k1() {
  A<1> a;
  f(a);             // error: deduction fails for conversion from int to short
  f<1>(a);          // OK
}

template<const short cs> class B { };
template<short s> void g(B<s>);
void k2() {
  B<1> b;
  g(b);             // OK: cv-qualifiers are ignored on template parameter types
}
```

— *end example*]

1 A *template-argument* can be deduced from a function, pointer to function, or pointer to member function type.

[*Example:*

```
template<class T> void f(void(*)(T,int));
template<class T> void foo(T,int);
void g(int,int);
void g(char,int);

void h(int,int,int);
void h(char,int);
int m() {
  f(&g);            // error: ambiguous
  f(&h);            // OK: void h(char,int) is a unique match
  f(&foo);          // error: type deduction fails because foo is a template
}
```

— *end example*]

2 A template *type-parameter* cannot be deduced from the type of a function default argument. [*Example:*

```
template <class T> void f(T = 5, T = 7);
void g() {
  f(1);             // OK: call f<int>(1,7)
  f();              // error: cannot deduce T
  f<int>();         // OK: call f<int>(5,7)
}
```

— *end example*]

1 The *template-argument* corresponding to a template *template-parameter* is deduced from the type of the *template-argument* of a class template specialization used in the argument list of a function call. [*Example:*

144) Although the *template-argument* corresponding to a *template-parameter* of type `bool` may be deduced from an array bound, the resulting value will always be `true` because the array bound will be non-zero.

```
template <template <class T> class X> struct A { };
template <template <class T> class X> void f(A<X>) { }
template<class T> struct B { };
A<B> ab;
f(ab);              // calls f(A<B>)
```

— *end example*]

2 [*Note:* Template argument deduction involving parameter packs (14.703.1) can deduce zero or more arguments for each parameter pack. — *end note*] [*Example:*

```
template<class> struct X { };
template<class R, class ... ArgTypes> struct X<R(int, ArgTypes ...)> { };
template<class ... Types> struct Y { };
template<class T, class ... Types> struct Y<T, Types& ...> { };

template<class ... Types> int f(void (*)(Types ...));
void g(int, float);

X<int> x1;                      // uses primary template
X<int(int, float, double)> x2;  // uses partial specialization; ArgTypes contains float, double
X<int(float, int)> x3;          // uses primary template
Y<> y1;                         // use primary template; Types is empty
Y<int&, float&, double&> y2;    // uses partial specialization; T is int&, Types contains float, double
Y<int, float, double> y3;       // uses primary template; Types contains int, float, double
int fv = f(g);                  // OK; Types contains int, float
```

— *end example*]

14.2655.0.1 Deducing template arguments from a function declaration [temp.deduct.decl]

1

In a declaration whose *declarator-id* refers to a specialization of a function template, template argument deduction is performed to identify the specialization to which the declaration refers. Specifically, this is done for explicit instantiations (14.1841.1), explicit specializations (14.1921.1), and certain friend declarations (14.755.1). This is also done to determine whether a deallocation function template specialization matches a placement `operator new` (3.2428.0.1, 5.2221.1). In all these cases, `P` is the type of the function template being considered as a potential match and `A` is either the function type from the declaration or the type of the deallocation function that would match the placement `operator new` as described in 5.2221.1. The deduction is done as described in 14.2492.0.1.

1

If, for the set of function templates so considered, there is either no match or more than one match after partial ordering has been considered (14.992.0.1), deduction fails and, in the declaration cases, the program is ill-formed.

14.2662.1 Overload resolution [temp.over]

1

A function template can be overloaded either by (non-template) functions of its name or by (other) function templates of the same name. When a call to that name is written (explicitly, or implicitly using the operator notation), template argument deduction (14.2114.1) and checking of any explicit template arguments (14.326) are performed for each function template to find the template argument values (if any) that can be used with that function template to instantiate a function template specialization that can be invoked with the call arguments. For each function template, if the argument deduction and checking succeeds, the *template-arguments* (deduced and/or explicit) are used to synthesize the declaration of a single function template

specialization which is added to the candidate functions set to be used in overload resolution. If, for a given function template, argument deduction fails, no such function is added to the set of candidate functions for that template. The complete set of candidate functions includes all the synthesized declarations and all of the non-template overloaded functions of the same name. The synthesized declarations are treated like any other functions in the remainder of overload resolution, except as explicitly noted in 13.562.1.[145]

[*Example:*

```
template<class T> T max(T a, T b) { return a>b?a:b; }

void f(int a, int b, char c, char d) {
  int m1 = max(a,b);            // max(int a, int b)
  char m2 = max(c,d);           // max(char a, char b)
  int m3 = max(a,c);            // error: cannot generate max(int,char)
}
```

1 Adding the non-template function

```
int max(int,int);
```

to the example above would resolve the third call, by providing a function that could be called for `max(a,c)` after using the standard conversion of `char` to `int` for `c`.

2 Here is an example involving conversions on a function argument involved in *template-argument* deduction:

```
template<class T> struct B { /* ... */ };
template<class T> struct D : public B<T> { /* ... */ };
template<class T> void f(B<T>&);

void g(B<int>& bi, D<int>& di) {
  f(bi);            // f(bi)
  f(di);            // f((B<int>&)di)
}
```

3 Here is an example involving conversions on a function argument not involved in *template-parameter* deduction:

```
template<class T> void f(T*,int);       // #1
template<class T> void f(T,char);       // #2

void h(int* pi, int i, char c) {
  f(pi,i);          // #1: f<int>(pi,i)
  f(pi,c);          // #2: f<int*>(pi,c)

  f(i,c);           // #2: f<int>(i,c);
  f(i,i);           // #2: f<int>(i,char(i))
}
```

— *end example*]

4

Only the signature of a function template specialization is needed to enter the specialization in a set of candidate functions. Therefore only the function template declaration is needed to resolve a call for which a template specialization is a candidate. [*Example:*

145) The parameters of function template specializations contain no template parameter types. The set of conversions allowed on deduced arguments is limited, because the argument deduction process produces function templates with parameters that either match the call arguments exactly or differ only in ways that can be bridged by the allowed limited conversions. Non-deduced arguments allow the full range of conversions. Note also that 13.562.1 specifies that a non-template function will be given preference over a template specialization if the two functions are otherwise equally good candidates for an overload match.

```
template<class T> void f(T);     // declaration

void g() {
  f("Annemarie");                // call of f<const char*>
}
```

1 The call of `f` is well-formed even if the template `f` is only declared and not defined at the point of the call. The program will be ill-formed unless a specialization for `f<const char*>`, either implicitly or explicitly generated, is present in some translation unit. — *end example*]

15 Exception handling [except]

1

Exception handling provides a way of transferring control and information from a point in the execution of a thread to an exception handler associated with a point previously passed by the execution. A handler will be invoked only by throwing an exception in code executed in the handler's try block or in functions called from the handler's try block.

try-block:
`try` *compound-statement handler-seq*

function-try-block:
`try` *ctor-initializer*$_{opt}$ *compound-statement handler-seq*

handler-seq:
handler handler-seq$_{opt}$

handler:
`catch (` *exception-declaration* `)` *compound-statement*

exception-declaration:
attribute-specifier-seq$_{opt}$ *type-specifier-seq declarator*
attribute-specifier-seq$_{opt}$ *type-specifier-seq abstract-declarator*$_{opt}$
`...`

throw-expression:
`throw` *assignment-expression*$_{opt}$

The optional *attribute-specifier-seq* in an *exception-declaration* appertains to the parameter of the catch clause (15.146).

1 A *try-block* is a *statement* (Clause 6). A *throw-expression* is of type `void`. [*Note:* Within this Clause "try block" is taken to mean both *try-block* and *function-try-block*. — *end note*]

2

A `goto` or `switch` statement shall not be used to transfer control into a try block or into a handler. [*Example:*

```
void f() {
  goto l1;          // Ill-formed
  goto l2;          // Ill-formed
  try {
    goto l1;        // OK
    goto l2;        // Ill-formed
    l1: ;
  } catch (...) {
    l2: ;
    goto l1;        // Ill-formed
    goto l2;        // OK
  }
}
```

— *end example*] A `goto`, `break`, `return`, or `continue` statement can be used to transfer control out of a try block or handler. When this happens, each variable declared in the try block will be destroyed in the context that directly contains its declaration. [*Example:*

```
lab:  try {
```

```
T1 t1;
try {
  T2 t2;
  if (condition)
    goto lab;
  } catch(...) { /* handler 2 */ }
} catch(...) { /* handler 1 */ }
```

Here, executing `goto lab;` will destroy first `t2`, then `t1`, assuming the *condition* does not declare a variable. Any exception raised while destroying `t2` will result in executing *handler 2*; any exception raised while destroying `t1` will result in executing *handler 1*. — *end example*]

1

A *function-try-block* associates a *handler-seq* with the *ctor-initializer*, if present, and the *compound-statement*. An exception thrown during the execution of the *compound-statement* or, for constructors and destructors, during the initialization or destruction, respectively, of the class's subobjects, transfers control to a handler in a *function-try-block* in the same way as an exception thrown during the execution of a *try-block* transfers control to other handlers. [*Example:*

```
int f(int);
class C {
  int i;
  double d;
public:
  C(int, double);
};

C::C(int ii, double id)
try : i(f(ii)), d(id) {
    // constructor statements
}
catch (...) {
    // handles exceptions thrown from the ctor-initializer
    // and from the constructor statements
}
```

— *end example*]

15.7 Throwing an exception [except.throw]

1

Throwing an exception transfers control to a handler. [*Note:* An exception can be thrown from one of the following contexts: *throw-expression* (see below), allocation functions (3.2361.0.1), `dynamic_cast` (5.1295.1), `typeid` (5.1393.1), *new-expression* (5.2221.1), and standard library functions (17.14.0.1). — *end note*] An object is passed and the type of that object determines which handlers can catch it. [*Example:*

```
throw "Help!";
```

can be caught by a *handler* of `const char*` type:

```
try {
    // ...
}
catch(const char* p) {
    // handle character string exceptions here
}
```

and

```
class Overflow {
public:
    Overflow(char,double,double);
};

void f(double x) {
    throw Overflow('+',x,3.45e107);
}
```

can be caught by a handler for exceptions of type `Overflow`

```
try {
    f(1.2);
} catch(Overflow& oo) {
    // handle exceptions of type Overflow here
}
```

— *end example*]

1

When an exception is thrown, control is transferred to the nearest handler with a matching type (15.146); "nearest" means the handler for which the *compound-statement* or *ctor-initializer* following the `try` keyword was most recently entered by the thread of control and not yet exited.

1

Throwing an exception copy-initializes (8.821, 12.1577) a temporary object, called the *exception object*. The temporary is an lvalue and is used to initialize the variable declared in the matching *handler* (15.146). If the type of the exception object would be an incomplete type or a pointer to an incomplete type other than (possibly cv-qualified) `void` the program is ill-formed. Evaluating a *throw-expression* with an operand throws an exception; the type of the exception object is determined by removing any top-level *cv-qualifiers* from the static type of the operand and adjusting the type from "array of `T`" or "function returning `T`" to "pointer to `T`" or "pointer to function returning `T`," respectively.

1

The memory for the exception object is allocated in an unspecified way, except as noted in 3.2361.0.1. If a handler exits by rethrowing, control is passed to another handler for the same exception. The exception object is destroyed after either the last remaining active handler for the exception exits by any means other than rethrowing, or the last object of type `std::exception_ptr` (18.254.1) that refers to the exception object is destroyed, whichever is later. In the former case, the destruction occurs when the handler exits, immediately after the destruction of the object declared in the *exception-declaration* in the handler, if any. In the latter case, the destruction occurs before the destructor of `std::exception_ptr` returns. The implementation may then deallocate the memory for the exception object; any such deallocation is done in an unspecified way. [*Note:* a thrown exception does not propagate to other threads unless caught, stored, and rethrown using appropriate library functions; see 18.254.1 and 30.179. — *end note*]

1

When the thrown object is a class object, the constructor selected for the copy-initialization and the destructor shall be accessible, even if the copy/move operation is elided (12.1577).

1 An exception is considered caught when a handler for that exception becomes active (15.146). [*Note:* An exception can have active handlers and still be considered uncaught if it is rethrown. — *end note*]

2

If the exception handling mechanism, after completing the initialization of the exception object but before the activation of a handler for the exception, calls a function that exits via an exception, `std::terminate` is called (15.308.1). [*Example:*

```
struct C {
  C() { }
  C(const C&) {
    if (std::uncaught_exception()) {
      throw 0;        // throw during copy to handler's exception-declaration object (15.146)
    }
  }
};

int main() {
  try {
    throw C();        // calls std::terminate() if construction of the handler's
                      // exception-declaration object is not elided (12.1577)
  } catch(C) { }
}
```

— *end example*]

1

A *throw-expression* with no operand rethrows the currently handled exception (15.146). The exception is reactivated with the existing exception object; no new exception object is created. The exception is no longer considered to be caught; therefore, the value of `std::uncaught_exception()` will again be `true`. [*Example:* code that must be executed because of an exception yet cannot completely handle the exception can be written like this:

```
try {
    // ...
} catch (...) {       // catch all exceptions
  // respond (partially) to exception
  throw;              // pass the exception to some
                      // other handler
}
```

— *end example*]

1

If no exception is presently being handled, executing a *throw-expression* with no operand calls `std::terminate()` (15.308.1).

15.89 Constructors and destructors [except.ctor]

1

As control passes from the point where an exception is thrown to a handler, destructors are invoked for all automatic objects constructed since the try block was entered. The automatic objects are destroyed in the reverse order of the completion of their construction.

1

An object of any storage duration whose initialization or destruction is terminated by an exception will have destructors executed for all of its fully constructed subobjects (excluding the variant members of a union-like class), that is, for subobjects for which the principal constructor (12.1026.1) has completed execution and the destructor has not yet begun execution. Similarly, if the non-delegating constructor for an object

has completed execution and a delegating constructor for that object exits with an exception, the object's destructor will be invoked. If the object was allocated in a *new-expression*, the matching deallocation function (3.2428.0.1, 5.2221.1, 12.988), if any, is called to free the storage occupied by the object.

1

The process of calling destructors for automatic objects constructed on the path from a try block to the point where an exception is thrown is called "*stack unwinding*." If a destructor called during stack unwinding exits with an exception, `std::terminate` is called (15.308.1). [*Note:* So destructors should generally catch exceptions and not let them propagate out of the destructor. — *end note*]

15.146 Handling an exception [except.handle]

1

The *exception-declaration* in a *handler* describes the type(s) of exceptions that can cause that *handler* to be entered. The *exception-declaration* shall not denote an incomplete type, an abstract class type, or an rvalue reference type. The *exception-declaration* shall not denote a pointer or reference to an incomplete type, other than `void*`, `const void*`, `volatile void*`, or `const volatile void*`.

1 A handler of type "array of `T`" or "function returning `T`" is adjusted to be of type "pointer to `T`" or "pointer to function returning `T`", respectively.

2

A *handler* is a match for an exception object of type `E` if

— The *handler* is of type *cv* `T` or *cv* `T&` and `E` and `T` are the same type (ignoring the top-level *cv-qualifiers*), or

— the *handler* is of type *cv* `T` or *cv* `T&` and `T` is an unambiguous public base class of `E`, or

— the *handler* is of type *cv* `T` or `const T&` where `T` is a pointer type and `E` is a pointer type that can be converted to `T` by either or both of

  — a standard pointer conversion (4.579) not involving conversions to pointers to private or protected or ambiguous classes

  — a qualification conversion, or

— the *handler* is of type *cv* `T` or `const T&` where `T` is a pointer or pointer to member type and `E` is `std::nullptr_t`.

[*Note:* A *throw-expression* whose operand is an integer literal with value zero does not match a handler of pointer or pointer to member type. — *end note*]

[*Example:*

```
class Matherr { /* ... */ virtual void vf(); };
class Overflow: public Matherr { /* ... */ };
class Underflow: public Matherr { /* ... */ };
class Zerodivide: public Matherr { /* ... */ };

void f() {
  try {
    g();
  } catch (Overflow oo) {
        // ...
  } catch (Matherr mm) {
        // ...
```

```
  }
}
```

Here, the `Overflow` handler will catch exceptions of type `Overflow` and the `Matherr` handler will catch exceptions of type `Matherr` and of all types publicly derived from `Matherr` including exceptions of type `Underflow` and `Zerodivide`. — *end example*]

1

The handlers for a try block are tried in order of appearance. That makes it possible to write handlers that can never be executed, for example by placing a handler for a derived class after a handler for a corresponding base class.

1

A `...` in a handler's *exception-declaration* functions similarly to `...` in a function parameter declaration; it specifies a match for any exception. If present, a `...` handler shall be the last handler for its try block.

1

If no match is found among the handlers for a try block, the search for a matching handler continues in a dynamically surrounding try block of the same thread.

1

A handler is considered active when initialization is complete for the parameter (if any) of the catch clause. [*Note:* The stack will have been unwound at that point. — *end note*] Also, an implicit handler is considered active when `std::terminate()` or `std::unexpected()` is entered due to a throw. A handler is no longer considered active when the catch clause exits or when `std::unexpected()` exits after being entered due to a throw.

1

The exception with the most recently activated handler that is still active is called the *currently handled exception*.

1

If no matching handler is found, the function `std::terminate()` is called; whether or not the stack is unwound before this call to `std::terminate()` is implementation-defined (15.308.1).

1

Referring to any non-static member or base class of an object in the handler for a *function-try-block* of a constructor or destructor for that object results in undefined behavior.

1

The fully constructed base classes and members of an object shall be destroyed before entering the handler of a *function-try-block* of a constructor for that object. Similarly, if a delegating constructor for an object exits with an exception after the non-delegating constructor for that object has completed execution, the object's destructor shall be executed before entering the handler of a *function-try-block* of a constructor for that object. The base classes and non-variant members of an object shall be destroyed before entering the handler of a *function-try-block* of a destructor for that object (12.807).

1 The scope and lifetime of the parameters of a function or constructor extend into the handlers of a *function-try-block*.

2

Exceptions thrown in destructors of objects with static storage duration or in constructors of namespace-scope objects with static storage duration are not caught by a *function-try-block* on `main()`. Exceptions thrown in destructors of objects with thread storage duration or in constructors of namespace-scope objects

with thread storage duration are not caught by a *function-try-block* on the initial function of the thread.

1

If a return statement appears in a handler of the *function-try-block* of a constructor, the program is ill-formed.

1

The currently handled exception is rethrown if control reaches the end of a handler of the *function-try-block* of a constructor or destructor. Otherwise, a function returns when control reaches the end of a handler for the *function-try-block* (6.270.2). Flowing off the end of a *function-try-block* is equivalent to a `return` with no value; this results in undefined behavior in a value-returning function (6.270.2).

1

The variable declared by the *exception-declaration*, of type *cv* `T` or *cv* `T&`, is initialized from the exception object, of type `E`, as follows:

— if `T` is a base class of `E`, the variable is copy-initialized (8.821) from the corresponding base class subobject of the exception object;

— otherwise, the variable is copy-initialized (8.821) from the exception object.

The lifetime of the variable ends when the handler exits, after the destruction of any automatic objects initialized within the handler.

1

When the handler declares an object, any changes to that object will not affect the exception object. When the handler declares a reference to an object, any changes to the referenced object are changes to the exception object and will have effect should that object be rethrown.

15.228 Exception specifications [except.spec]

1

A function declaration lists exceptions that its function might directly or indirectly throw by using an *exception-specification* as a suffix of its declarator.

exception-specification:
  dynamic-exception-specification
  noexcept-specification

dynamic-exception-specification:
  `throw (` *type-id-list*$_{opt}$`)`

type-id-list:
  type-id `...`$_{opt}$
  type-id-list `,` *type-id* `...`$_{opt}$

noexcept-specification:
  `noexcept (` *constant-expression* `)`
  `noexcept`

In a *noexcept-specification*, the *constant-expression*, if supplied, shall be a constant expression (5.3643) that is contextually converted to `bool` (Clause 4). A *noexcept-specification* `noexcept` is equivalent to `noexcept(true)`. A `(` token that follows `noexcept` is part of the *noexcept-specification* and does not commence an initializer (8.821).

1

An *exception-specification* shall appear only on a function declarator for a function type, pointer to function type, reference to function type, or pointer to member function type that is the top-level type of a declaration or definition, or on such a type appearing as a parameter or return type in a function declarator. An *exception-specification* shall not appear in a typedef declaration or *alias-declaration*. [*Example:*

```
void f() throw(int);                    // OK
void (*fp)() throw (int);               // OK
void g(void pfa() throw(int));          // OK
typedef int (*pf)() throw(int);         // ill-formed
```

— *end example*]

A type denoted in an *exception-specification* shall not denote an incomplete type or an rvalue reference type. A type denoted in an *exception-specification* shall not denote a pointer or reference to an incomplete type, other than *cv* `void*`. A type *cv* `T`, "array of `T`", or "function returning `T`" denoted in an *exception-specification* is adjusted to type `T`, "pointer to `T`", or "pointer to function returning `T`", respectively.

1

Two *exception-specification*s are *compatible* if:

— both are non-throwing (see below), regardless of their form,

— both have the form `noexcept(`*constant-expression*`)` and the *constant-expression*s are equivalent, or

— both are *dynamic-exception-specification*s that have the same set of adjusted types.

1

If any declaration of a function has an *exception-specification* that is not a *noexcept-specification* allowing all exceptions, all declarations, including the definition and any explicit specialization, of that function shall have a compatible *exception-specification*. If any declaration of a pointer to function, reference to function, or pointer to member function has an *exception-specification*, all occurrences of that declaration shall have a compatible *exception-specification* In an explicit instantiation an *exception-specification* may be specified, but is not required. If an *exception-specification* is specified in an explicit instantiation directive, it shall be compatible with the *exception-specification*s of other declarations of that function. A diagnostic is required only if the *exception-specification*s are not compatible within a single translation unit.

1

If a virtual function has an *exception-specification*, all declarations, including the definition, of any function that overrides that virtual function in any derived class shall only allow exceptions that are allowed by the *exception-specification* of the base class virtual function. [*Example:*

```
struct B {
  virtual void f() throw (int, double);
  virtual void g();
};

struct D: B {
  void f();                     // ill-formed
  void g() throw (int);         // OK
};
```

The declaration of `D::f` is ill-formed because it allows all exceptions, whereas `B::f` allows only `int` and `double`. — *end example*] A similar restriction applies to assignment to and initialization of pointers to functions, pointers to member functions, and references to functions: the target entity shall allow at least the exceptions allowed by the source value in the assignment or initialization. [*Example:*

```
class A { /* ... */ };
void (*pf1)();       // no exception specification
void (*pf2)() throw(A);

void f() {
```

```
  pf1 = pf2;          // OK: pf1 is less restrictive
  pf2 = pf1;          // error: pf2 is more restrictive
}
```

— *end example*]

1 In such an assignment or initialization, *exception-specification*s on return types and parameter types shall be compatible. In other assignments or initializations, *exception-specification*s shall be compatible.

2

An *exception-specification* can include the same type more than once and can include classes that are related by inheritance, even though doing so is redundant. [*Note:* An *exception-specification* can also include the class `std::bad_exception` (18.247.1). — *end note*]

1

A function is said to *allow* an exception of type `E` if the *constant-expression* in its *noexcept-specification* evaluates to `false` or its *dynamic-exception-specification* contains a type `T` for which a handler of type `T` would be a match (15.146) for an exception of type `E`.

1

Whenever an exception is thrown and the search for a handler (15.146) encounters the outermost block of a function with an *exception-specification* that does not allow the exception, then,

— if the *exception-specification* is a *dynamic-exception-specification*, the function `std::unexpected()` is called (15.370.1),

— otherwise, the function `std::terminate()` is called (15.308.1).

[*Example:*

```
class X { };
class Y { };
class Z: public X { };
class W { };

void f() throw (X, Y) {
  int n = 0;
  if (n) throw X();          // OK
  if (n) throw Z();          // also OK
  throw W();                 // will call std::unexpected()
}
```

— *end example*]

[*Note:* A function can have multiple declarations with different non-throwing *exception-specification*s; for this purpose, the one on the function definition is used. — *end note*]

1 The function `unexpected()` may throw an exception that will satisfy the *exception-specification* for which it was invoked, and in this case the search for another handler will continue at the call of the function with this *exception-specification* (see 15.370.1), or it may call `std::terminate()`.

2

An implementation shall not reject an expression merely because when executed it throws or might throw an exception that the containing function does not allow. [*Example:*

```
extern void f() throw(X, Y);

void g() throw(X) {
```

```
  f();                          // OK
}
```

the call to `f` is well-formed even though when called, `f` might throw exception `Y` that `g` does not allow. — *end example*]

1

A function with no *exception-specification* or with an *exception-specification* of the form `noexcept(`*constant-expression* `)` where the *constant-expression* yields `false` allows all exceptions. An *exception-specification* is *non-throwing* if it is of the form `throw()`, `noexcept`, or `noexcept(`*constant-expression* `)` where the *constant-expression* yields `true`. A function with a non-throwing *exception-specification* does not allow any exceptions.

1 An *exception-specification* is not considered part of a function's type.

2

An inheriting constructor (12.2400) and an implicitly declared special member function (Clause 12) have an *exception-specification*. If `f` is an inheriting constructor or an implicitly declared default constructor, copy constructor, move constructor, destructor, copy assignment operator, or move assignment operator, its implicit *exception-specification* specifies the *type-id* `T` if and only if `T` is allowed by the *exception-specification* of a function directly invoked by `f`'s implicit definition; `f` allows all exceptions if any function it directly invokes allows all exceptions, and `f` has the *exception-specification* `noexcept(true)` if every function it directly invokes allows no exceptions. [*Note:* It follows that `f` has the *exception-specification* `noexcept(true)` if it invokes no other functions. — *end note*] [*Note:* An instantiation of an inheriting constructor template has an implied *exception-specification* as if it were a non-template inheriting constructor. — *end note*] [*Example:*

```
struct A {
  A();
  A(const A&) throw();
  A(A&&) throw();
  ~A() throw(X);
};
struct B {
  B() throw();
  B(const B&) = default; // Declaration of B::B(const B&) noexcept(true)
  B(B&&) throw(Y);
  ~B() throw(Y);
};
struct D : public A, public B {
    // Implicit declaration of D::D();
    // Implicit declaration of D::D(const D&) noexcept(true);
    // Implicit declaration of D::D(D&&) throw(Y);
    // Implicit declaration of D::~D() throw(X, Y);
};
```

Furthermore, if `A::~A()` or `B::~B()` were virtual, `D::~D()` would not be as restrictive as that of `A::~A`, and the program would be ill-formed since a function that overrides a virtual function from a base class shall have an *exception-specification* at least as restrictive as that in the base class. — *end example*]

1 A deallocation function (3.2428.0.1) with no explicit *exception-specification* is treated as if it were specified with `noexcept(true)`.

2 An *exception-specification* is considered to be *needed* when:

(2.1) — in an expression, the function is the unique lookup result or the selected member of a set of overloaded functions (3.923, 13.88, 13.1084);

(2.2) — the function is odr-used (3.91) or, if it appears in an unevaluated operand, would be odr-used if the expression were potentially-evaluated;

(2.3) — the *exception-specification* is compared to that of another declaration (e.g., an explicit specialization or an overriding virtual function);

(2.4) — the function is defined; or

(2.5) — the *exception-specification* is needed for a defaulted special member function that calls the function. [*Note:* A defaulted declaration does not require the *exception-specification* of a base member function to be evaluated until the implicit *exception-specification* of the derived function is needed, but an explicit *exception-specification* needs the implicit *exception-specification* to compare against. — *end note*]

The *exception-specification* of a defaulted special member function is evaluated as described above only when needed; similarly, the *exception-specification* of a specialization of a function template or member function of a class template is instantiated only when needed.

3 In a *dynamic-exception-specification*, a *type-id* followed by an ellipsis is a pack expansion (14.703.1).

4

[*Note:* The use of *dynamic-exception-specification*s is deprecated (see Annex D). — *end note*]

15.308 Special functions [except.special]

1 The functions `std::terminate()` (15.308.1) and `std::unexpected()` (15.370.1) are used by the exception handling mechanism for coping with errors related to the exception handling mechanism itself. The function `std::current_exception()` (18.254.1) and the class `std::nested_exception` (18.265.1) can be used by a program to capture the currently handled exception.

15.308.1 The `std::terminate()` function [except.terminate]

1

In some situations exception handling must be abandoned for less subtle error handling techniques. [*Note:* These situations are:

— when the exception handling mechanism, after completing the initialization of the exception object but before activation of a handler for the exception (15.7), calls a function that exits via an exception, or

— when the exception handling mechanism cannot find a handler for a thrown exception (15.146), or

— when the search for a handler (15.146) encounters the outermost block of a function with a *noexcept-specification* that does not allow the exception (15.228), or

— when the destruction of an object during stack unwinding (15.89) terminates by throwing an exception, or

— when initialization of a non-local variable with static or thread storage duration (3.1937.1) exits via an exception, or

— when destruction of an object with static or thread storage duration exits via an exception (3.2200.1), or

— when execution of a function registered with `std::atexit` or `std::at_quick_exit` exits via an exception (18.127), or

— when a *throw-expression* with no operand attempts to rethrow an exception and no exception is being handled (15.7), or

— when `std::unexpected` throws an exception which is not allowed by the previously violated *dynamic-exception-specification*, and `std::bad_exception` is not included in that *dynamic-exception-specification* (15.370.1), or

— when the implementation's default unexpected exception handler is called (D.62.1), or

— when the function `std::nested_exception::rethrow_nested` is called for an object that has captured no exception (18.265.1), or

— when execution of the initial function of a thread exits via an exception (30.31.0.1), or

— when the destructor or the copy assignment operator is invoked on an object of type `std::thread` that refers to a joinable thread (30.60.0.1, 30.74.0.1).

— *end note*]

1

In such cases, `std::terminate()` is called (18.247.2). In the situation where no matching handler is found, it is implementation-defined whether or not the stack is unwound before `std::terminate()` is called. In the situation where the search for a handler (15.146) encounters the outermost block of a function with a *noexcept-specification* that does not allow the exception (15.228), it is implementation-defined whether the stack is unwound, unwound partially, or not unwound at all before `std::terminate()` is called. In all other situations, the stack shall not be unwound before `std::terminate()` is called. An implementation is not permitted to finish stack unwinding prematurely based on a determination that the unwind process will eventually cause a call to `std::terminate()`.

15.370.1 The `std::unexpected()` function [except.unexpected]

1 If a function with a *dynamic-exception-specification* throws an exception that is not listed in the *dynamic-exception-specification*, the function `std::unexpected()` is called (D.62) immediately after completing the stack unwinding for the former function.

2 [*Note:* By default, `std::unexpected()` calls `std::terminate()`, but a program can install its own handler function (D.62.2). In either case, the constraints in the following paragraph apply. — *end note*]

3

The `std::unexpected()` function shall not return, but it can throw (or re-throw) an exception. If it throws a new exception which is allowed by the exception specification which previously was violated, then the search for another handler will continue at the call of the function whose exception specification was violated. If it throws or rethrows an exception that the *dynamic-exception-specification* does not allow then the following happens: If the *dynamic-exception-specification* does not include the class `std::bad_exception` (18.247.1) then the function `std::terminate()` is called, otherwise the thrown exception is replaced by an implementation-defined object of the type `std::bad_exception` and the search for another handler will continue at the call of the function whose *dynamic-exception-specification* was violated.

1 Thus, a *dynamic-exception-specification* guarantees that only the listed exceptions will be thrown. If the *dynamic-exception-specification* includes the type `std::bad_exception` then any exception not on the list may be replaced by `std::bad_exception` within the function `std::unexpected()`.

15.371.1 The `std::uncaught_exception()` function [except.uncaught]

1

The function `std::uncaught_exception()` returns `true` after completing the initialization of the exception object (15.7) until completing the activation of a handler for the exception (15.146, 18.253.1). This includes

stack unwinding. If the exception is rethrown (15.7), `std::uncaught_exception()` returns `true` from the point of rethrow until the rethrown exception is caught again.

16 Preprocessing directives [cpp]

1

A *preprocessing directive* consists of a sequence of preprocessing tokens that satisfies the following constraints: The first token in the sequence is a `#` preprocessing token that (at the start of translation phase 4) is either the first character in the source file (optionally after white space containing no new-line characters) or that follows white space containing at least one new-line character. The last token in the sequence is the first new-line character that follows the first token in the sequence.[146] A new-line character ends the preprocessing directive even if it occurs within what would otherwise be an invocation of a function-like macro.

preprocessing-file:
  group$_{opt}$

group:
  group-part
  group group-part

group-part:
  if-section
  control-line
  text-line
  `#` *non-directive*

if-section:
  if-group elif-groups$_{opt}$ *else-group*$_{opt}$ *endif-line*

if-group:
  `# if` *constant-expression new-line group*$_{opt}$
  `# ifdef` *identifier new-line group*$_{opt}$
  `# ifndef` *identifier new-line group*$_{opt}$

elif-groups:
  elif-group
  elif-groups elif-group

elif-group:
  `# elif` *constant-expression new-line group*$_{opt}$

else-group:
  `# else` *new-line group*$_{opt}$

endif-line:
  `# endif` *new-line*

146) Thus, preprocessing directives are commonly called "lines." These "lines" have no other syntactic significance, as all white space is equivalent except in certain situations during preprocessing (see the `#` character string literal creation operator in 16.161.1, for example).

control-line:
`# include` *pp-tokens new-line*
`# define` *identifier replacement-list new-line*
`# define` *identifier lparen identifier-list*$_{opt}$ `)` *replacement-list new-line*
`# define` *identifier lparen* `...` `)` *replacement-list new-line*
`# define` *identifier lparen identifier-list,* `...` `)` *replacement-list new-line*
`# undef` *identifier new-line*
`# line` *pp-tokens new-line*
`# error` *pp-tokens*$_{opt}$ *new-line*
`# pragma` *pp-tokens*$_{opt}$ *new-line*
`#` *new-line*

text-line:
pp-tokens$_{opt}$ *new-line*

non-directive:
pp-tokens new-line

lparen:
a `(` character not immediately preceded by white-space

identifier-list:
identifier
identifier-list `,` *identifier*

replacement-list:
pp-tokens$_{opt}$

pp-tokens:
preprocessing-token
pp-tokens preprocessing-token

new-line:
the new-line character

1

A text line shall not begin with a `#` preprocessing token. A non-directive shall not begin with any of the directive names appearing in the syntax.

1 When in a group that is skipped (16.18), the directive syntax is relaxed to allow any sequence of preprocessing tokens to occur between the directive name and the following new-line character.

2

The only white-space characters that shall appear between preprocessing tokens within a preprocessing directive (from just after the introducing `#` preprocessing token through just before the terminating new-line character) are space and horizontal-tab (including spaces that have replaced comments or possibly other white-space characters in translation phase 3).

1

The implementation can process and skip sections of source files conditionally, include other source files, and replace macros. These capabilities are called *preprocessing*, because conceptually they occur before translation of the resulting translation unit.

1

The preprocessing tokens within a preprocessing directive are not subject to macro expansion unless otherwise stated.

[*Example:* In:

```
#define EMPTY
EMPTY   #   include <file.h>
```

the sequence of preprocessing tokens on the second line is *not* a preprocessing directive, because it does not begin with a # at the start of translation phase 4, even though it will do so after the macro `EMPTY` has been replaced. — *end example*]

16.18 Conditional inclusion [cpp.cond]

1

The expression that controls conditional inclusion shall be an integral constant expression except that identifiers (including those lexically identical to keywords) are interpreted as described below[147] and it may contain unary operator expressions of the form

`defined` *identifier*

or

`defined (` *identifier* `)`

which evaluate to `1` if the identifier is currently defined as a macro name (that is, if it is predefined or if it has been the subject of a `#define` preprocessing directive without an intervening `#undef` directive with the same subject identifier), `0` if it is not.

1 Each preprocessing token that remains (in the list of preprocessing tokens that will become the controlling expression) after all macro replacements have occurred shall be in the lexical form of a token (2.247).

2 Preprocessing directives of the forms

`# if` *constant-expression new-line* $group_{opt}$
`# elif` *constant-expression new-line* $group_{opt}$

check whether the controlling constant expression evaluates to nonzero.

3

Prior to evaluation, macro invocations in the list of preprocessing tokens that will become the controlling constant expression are replaced (except for those macro names modified by the `defined` unary operator), just as in normal text. If the token `defined` is generated as a result of this replacement process or use of the `defined` unary operator does not match one of the two specified forms prior to macro replacement, the behavior is undefined. After all replacements due to macro expansion and the `defined` unary operator have been performed, all remaining identifiers and keywords[148], except for `true` and `false`, are replaced with the pp-number `0`, and then each preprocessing token is converted into a token. The resulting tokens comprise the controlling constant expression which is evaluated according to the rules of 5.3643 using arithmetic that has at least the ranges specified in 18.41. For the purposes of this token conversion and evaluation all signed and unsigned integer types act as if they have the same representation as, respectively, `intmax_t` or `uintmax_t` (18.114).[149] This includes interpreting character literals, which may involve converting escape sequences into execution character set members. Whether the numeric value for these character literals matches the value obtained when an identical character literal occurs in an expression (other than within a `#if` or `#elif` directive) is implementation-defined.[150] Also, whether a single-character character literal may

147) Because the controlling constant expression is evaluated during translation phase 4, all identifiers either are or are not macro names — there simply are no keywords, enumeration constants, etc.

148) An alternative token (2.236) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not subject to this replacement.

149) Thus on an implementation where `std::numeric_limits<int>::max()` is `0x7FFF` and `std::numeric_limits<unsigned int>::max()` is `0xFFFF`, the integer literal `0x8000` is signed and positive within a `#if` expression even though it is unsigned in translation phase 7 (2.6).

150) Thus, the constant expression in the following `#if` directive and `if` statement is not guaranteed to evaluate to the same value in these two contexts.

```
#if 'z' - 'a' == 25
if ('z' - 'a' == 25)
```

have a negative value is implementation-defined. Each subexpression with type `bool` is subjected to integral promotion before processing continues.

1 Preprocessing directives of the forms

`# ifdef` *identifier new-line* $group_{opt}$
`# ifndef` *identifier new-line* $group_{opt}$

check whether the identifier is or is not currently defined as a macro name. Their conditions are equivalent to `#if defined` *identifier* and `#if !defined` *identifier* respectively.

2

Each directive's condition is checked in order. If it evaluates to false (zero), the group that it controls is skipped: directives are processed only through the name that determines the directive in order to keep track of the level of nested conditionals; the rest of the directives' preprocessing tokens are ignored, as are the other preprocessing tokens in the group. Only the first group whose control condition evaluates to true (nonzero) is processed. If none of the conditions evaluates to true, and there is a `#else` directive, the group controlled by the `#else` is processed; lacking a `#else` directive, all the groups until the `#endif` are skipped.[151]

16.48 Source file inclusion [cpp.include]

1

A `#include` directive shall identify a header or source file that can be processed by the implementation.

1

A preprocessing directive of the form

`# include <` *h-char-sequence*`>` *new-line*

searches a sequence of implementation-defined places for a header identified uniquely by the specified sequence between the `<` and `>` delimiters, and causes the replacement of that directive by the entire contents of the header. How the places are specified or the header identified is implementation-defined.

1

A preprocessing directive of the form

`# include "` *q-char-sequence*`"` *new-line*

causes the replacement of that directive by the entire contents of the source file identified by the specified sequence between the `"` delimiters. The named source file is searched for in an implementation-defined manner. If this search is not supported, or if the search fails, the directive is reprocessed as if it read

`# include <` *h-char-sequence*`>` *new-line*

with the identical contained sequence (including `>` characters, if any) from the original directive.

1

A preprocessing directive of the form

`# include` *pp-tokens new-line*

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after `include` in the directive are processed just as in normal text (i.e., each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined.[152] The method by which a sequence

151) As indicated by the syntax, a preprocessing token shall not follow a `#else` or `#endif` directive before the terminating new-line character. However, comments may appear anywhere in a source file, including within a preprocessing directive.
152) Note that adjacent string literals are not concatenated into a single string literal (see the translation phases in 2.6); thus, an expansion that results in two string literals is an invalid directive.

of preprocessing tokens between a `<` and a `>` preprocessing token pair or a pair of `"` characters is combined into a single header name preprocessing token is implementation-defined.

1

The implementation shall provide unique mappings for sequences consisting of one or more *nondigit*s or *digit*s (2.268) followed by a period (`.`) and a single *nondigit*. The first character shall not be a *digit*. The implementation may ignore distinctions of alphabetical case.

1

A `#include` preprocessing directive may appear in a source file that has been read because of a `#include` directive in another file, up to an implementation-defined nesting limit.

1 [*Note:* Although an implementation may provide a mechanism for making arbitrary source files available to the `< >` search, in general programmers should use the `< >` form for headers provided with the implementation, and the `" "` form for sources outside the control of the implementation. For instance:

```
#include <stdio.h>
#include <unistd.h>
#include "usefullib.h"
#include "myprog.h"
```

— *end note*]

2 [*Example:* This illustrates macro-replaced `#include` directives:

```
#if VERSION == 1
    #define INCFILE  "vers1.h"
#elif VERSION == 2
    #define INCFILE  "vers2.h"   // and so on
#else
    #define INCFILE  "versN.h"
#endif
#include INCFILE
```

— *end example*]

16.116 Macro replacement [cpp.replace]

1 Two replacement lists are identical if and only if the preprocessing tokens in both have the same number, ordering, spelling, and white-space separation, where all white-space separations are considered identical.

2

An identifier currently defined as an *object-like* macro may be redefined by another `#define` preprocessing directive provided that the second definition is an object-like macro definition and the two replacement lists are identical, otherwise the program is ill-formed. Likewise, an identifier currently defined as a *function-like* macro may be redefined by another `#define` preprocessing directive provided that the second definition is a function-like macro definition that has the same number and spelling of parameters, and the two replacement lists are identical, otherwise the program is ill-formed.

1

There shall be white-space between the identifier and the replacement list in the definition of an object-like macro.

1

If the identifier-list in the macro definition does not end with an ellipsis, the number of arguments (including those arguments consisting of no preprocessing tokens) in an invocation of a function-like macro shall equal the number of parameters in the macro definition. Otherwise, there shall be more arguments in the invocation

than there are parameters in the macro definition (excluding the `...`). There shall exist a `)` preprocessing token that terminates the invocation.

1 The identifier `__VA_ARGS__` shall occur only in the replacement-list of a function-like macro that uses the ellipsis notation in the parameters.

2 A parameter identifier in a function-like macro shall be uniquely declared within its scope.

3 The identifier immediately following the `define` is called the *macro name*. There is one name space for macro names. Any white-space characters preceding or following the replacement list of preprocessing tokens are not considered part of the replacement list for either form of macro.

4

If a `#` preprocessing token, followed by an identifier, occurs lexically at the point at which a preprocessing directive could begin, the identifier is not subject to macro replacement.

1

A preprocessing directive of the form

`#` `define` *identifier replacement-list new-line*

defines an *object-like macro* that causes each subsequent instance of the macro name[153] to be replaced by the replacement list of preprocessing tokens that constitute the remainder of the directive.[154] The replacement list is then rescanned for more macro names as specified below.

1

A preprocessing directive of the form

`#` `define` *identifier lparen identifier-list*$_{opt}$`)` *replacement-list new-line*
`#` `define` *identifier lparen* `...` `)` *replacement-list new-line*
`#` `define` *identifier lparen identifier-list* `,` `...` `)` *replacement-list new-line*

defines a *function-like macro* with parameters, whose use is similar syntactically to a function call. The parameters are specified by the optional list of identifiers, whose scope extends from their declaration in the identifier list until the new-line character that terminates the `#define` preprocessing directive. Each subsequent instance of the function-like macro name followed by a `(` as the next preprocessing token introduces the sequence of preprocessing tokens that is replaced by the replacement list in the definition (an invocation of the macro). The replaced sequence of preprocessing tokens is terminated by the matching `)` preprocessing token, skipping intervening matched pairs of left and right parenthesis preprocessing tokens. Within the sequence of preprocessing tokens making up an invocation of a function-like macro, new-line is considered a normal white-space character.

1

The sequence of preprocessing tokens bounded by the outside-most matching parentheses forms the list of arguments for the function-like macro. The individual arguments within the list are separated by comma preprocessing tokens, but comma preprocessing tokens between matching inner parentheses do not separate arguments. If there are sequences of preprocessing tokens within the list of arguments that would otherwise act as preprocessing directives,[155] the behavior is undefined.

1

If there is a `...` immediately preceding the `)` in the function-like macro definition, then the trailing arguments, including any separating comma preprocessing tokens, are merged to form a single item: the *variable*

153) Since, by macro-replacement time, all character literals and string literals are preprocessing tokens, not sequences possibly containing identifier-like subsequences (see 2.6, translation phases), they are never scanned for macro names or parameters.
154) An alternative token (2.236) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not possible to define a macro whose name is the same as that of an alternative token.
155) Despite the name, a non-directive is a preprocessing directive.

arguments. The number of arguments so combined is such that, following merger, the number of arguments is one more than the number of parameters in the macro definition (excluding the `...`).

16.146.1 Argument substitution [cpp.subst]

1

After the arguments for the invocation of a function-like macro have been identified, argument substitution takes place. A parameter in the replacement list, unless preceded by a `#` or `##` preprocessing token or followed by a `##` preprocessing token (see below), is replaced by the corresponding argument after all macros contained therein have been expanded. Before being substituted, each argument's preprocessing tokens are completely macro replaced as if they formed the rest of the preprocessing file; no other preprocessing tokens are available.

1

An identifier `__VA_ARGS__` that occurs in the replacement list shall be treated as if it were a parameter, and the variable arguments shall form the preprocessing tokens used to replace it.

16.161.1 The # operator [cpp.stringize]

1 Each `#` preprocessing token in the replacement list for a function-like macro shall be followed by a parameter as the next preprocessing token in the replacement list.

2

A *character string literal* is a *string-literal* with no prefix. If, in the replacement list, a parameter is immediately preceded by a `#` preprocessing token, both are replaced by a single character string literal preprocessing token that contains the spelling of the preprocessing token sequence for the corresponding argument. Each occurrence of white space between the argument's preprocessing tokens becomes a single space character in the character string literal. White space before the first preprocessing token and after the last preprocessing token comprising the argument is deleted. Otherwise, the original spelling of each preprocessing token in the argument is retained in the character string literal, except for special handling for producing the spelling of string literals and character literals: a `\` character is inserted before each `"` and `\` character of a character literal or string literal (including the delimiting `"` characters). If the replacement that results is not a valid character string literal, the behavior is undefined. The character string literal corresponding to an empty argument is `""`. The order of evaluation of `#` and `##` operators is unspecified.

16.175.1 The ## operator [cpp.concat]

1

A `##` preprocessing token shall not occur at the beginning or at the end of a replacement list for either form of macro definition.

1

If, in the replacement list of a function-like macro, a parameter is immediately preceded or followed by a `##` preprocessing token, the parameter is replaced by the corresponding argument's preprocessing token sequence; however, if an argument consists of no preprocessing tokens, the parameter is replaced by a placemarker preprocessing token instead.[156]

1

For both object-like and function-like macro invocations, before the replacement list is reexamined for more macro names to replace, each instance of a `##` preprocessing token in the replacement list (not from an argument) is deleted and the preceding preprocessing token is concatenated with the following preprocessing

156) Placemarker preprocessing tokens do not appear in the syntax because they are temporary entities that exist only within translation phase 4.

token. Placemarker preprocessing tokens are handled specially: concatenation of two placemarkers results in a single placemarker preprocessing token, and concatenation of a placemarker with a non-placemarker preprocessing token results in the non-placemarker preprocessing token. If the result is not a valid preprocessing token, the behavior is undefined. The resulting token is available for further macro replacement. The order of evaluation of `##` operators is unspecified.

[*Example:* In the following fragment:

```
#define hash_hash # ## #
#define mkstr(a) # a
#define in_between(a) mkstr(a)
#define join(c, d) in_between(c hash_hash d)
char p[] = join(x, y);          // equivalent to
                                // char p[] = "x ## y";
```

The expansion produces, at various stages:

```
join(x, y)
in_between(x hash_hash y)
in_between(x ## y)
mkstr(x ## y)
"x ## y"
```

In other words, expanding `hash_hash` produces a new token, consisting of two adjacent sharp signs, but this new token is not the `##` operator. — *end example*]

16.187.1 Rescanning and further replacement [cpp.rescan]

1

After all parameters in the replacement list have been substituted and `#` and `##` processing has taken place, all placemarker preprocessing tokens are removed. Then the resulting preprocessing token sequence is rescanned, along with all subsequent preprocessing tokens of the source file, for more macro names to replace.

1

If the name of the macro being replaced is found during this scan of the replacement list (not including the rest of the source file's preprocessing tokens), it is not replaced. Furthermore, if any nested replacements encounter the name of the macro being replaced, it is not replaced. These nonreplaced macro name preprocessing tokens are no longer available for further replacement even if they are later (re)examined in contexts in which that macro name preprocessing token would otherwise have been replaced.

1

The resulting completely macro-replaced preprocessing token sequence is not processed as a preprocessing directive even if it resembles one, but all pragma unary operator expressions within it are then processed as specified in 16.276 below.

16.220.1 Scope of macro definitions [cpp.scope]

1 A macro definition lasts (independent of block structure) until a corresponding `#undef` directive is encountered or (if none is encountered) until the end of the translation unit. Macro definitions have no significance after translation phase 4.

2

A preprocessing directive of the form

`# undef` *identifier new-line*

causes the specified identifier no longer to be defined as a macro name. It is ignored if the specified identifier is not currently defined as a macro name.

1 [*Example:* The simplest use of this facility is to define a "manifest constant," as in

```
#define TABSIZE 100
int table[TABSIZE];
```

— *end example*]

2 [*Example:* The following defines a function-like macro whose value is the maximum of its arguments. It has the advantages of working for any compatible types of the arguments and of generating in-line code without the overhead of function calling. It has the disadvantages of evaluating one or the other of its arguments a second time (including side effects) and generating more code than a function if invoked several times. It also cannot have its address taken, as it has none.

```
#define max(a, b) ((a) > (b) ? (a) : (b))
```

The parentheses ensure that the arguments and the resulting expression are bound properly. — *end example*]

3 [*Example:* To illustrate the rules for redefinition and reexamination, the sequence

```
#define x       3
#define f(a)    f(x * (a))
#undef  x
#define x       2
#define g       f
#define z       z[0]
#define h       g(~
#define m(a)    a(w)
#define w       0,1
#define t(a)    a
#define p()     int
#define q(x)    x
#define r(x,y)  x ## y
#define str(x)  # x

f(y+1) + f(f(z)) % t(t(g)(0) + t)(1);
g(x+(3,4)-w) | h 5) & m
    (f)^m(m);
p() i[q()] = { q(1), r(2,3), r(4,), r(,5), r(,) };
char c[2][6] = { str(hello), str() };
```

results in

```
f(2 * (y+1)) + f(2 * (f(2 * (z[0])))) % f(2 * (0)) + t(1);
f(2 * (2+(3,4)-0,1)) | f(2 * (~ 5)) & f(2 * (0,1))^m(0,1);
int i[] = { 1, 23, 4, 5, };
char c[2][6] = { "hello", "" };
```

— *end example*]

4 [*Example:* To illustrate the rules for creating character string literals and concatenating tokens, the sequence

```
#define str(s)      # s
#define xstr(s)     str(s)
#define debug(s, t) printf("x" # s "= %d, x" # t "= %s", \
                x ## s, x ## t)
#define INCFILE(n)  vers ## n
```

```
#define glue(a, b)  a ## b
#define xglue(a, b) glue(a, b)
#define HIGHLOW     "hello"
#define LOW         LOW ", world"

debug(1, 2);
fputs(str(strncmp("abc\0d", "abc", '\4')  // this goes away
    == 0) str(: @\n), s);
#include xstr(INCFILE(2).h)
glue(HIGH, LOW);
xglue(HIGH, LOW)
```

results in

```
printf("x" "1" "= %d, x" "2" "= %s", x1, x2);
fputs("strncmp(\"abc\\0d\", \"abc\", '\\4') == 0" ": @\n", s);
#include "vers2.h"    (after macro replacement, before file access)
"hello";
"hello" ", world"
```

or, after concatenation of the character string literals,

```
printf("x1= %d, x2= %s", x1, x2);
fputs("strncmp(\"abc\\0d\", \"abc\", '\\4') == 0: @\n", s);
#include "vers2.h"    (after macro replacement, before file access)
"hello";
"hello, world"
```

Space around the # and ## tokens in the macro definition is optional. — *end example*]

5 [*Example:* To illustrate the rules for placemarker preprocessing tokens, the sequence

```
#define t(x,y,z) x ## y ## z
int j[] = { t(1,2,3), t(,4,5), t(6,,7), t(8,9,),
  t(10,,), t(,11,), t(,,12), t(,,) };
```

results in

```
int j[] = { 123, 45, 67, 89,
  10, 11, 12, };
```

— *end example*]

6 [*Example:* To demonstrate the redefinition rules, the following sequence is valid.

```
#define OBJ_LIKE      (1-1)
#define OBJ_LIKE      /* white space */ (1-1) /* other */
#define FUNC_LIKE(a)   ( a )
#define FUNC_LIKE( a )(     /* note the white space */ \
                a /* other stuff on this line
                  */ )
```

But the following redefinitions are invalid:

```
#define OBJ_LIKE    (0)       // different token sequence
#define OBJ_LIKE    (1 - 1)   // different white space
#define FUNC_LIKE(b) ( a )    // different parameter usage
#define FUNC_LIKE(b) ( b )    // different parameter spelling
```

— *end example*]

7 [*Example:* Finally, to show the variable argument list macro facilities:

```
#define debug(...) fprintf(stderr, __VA_ARGS__)
#define showlist(...) puts(#__VA_ARGS__)
#define report(test, ...) ((test) ? puts(#test) : printf(__VA_ARGS__))
debug("Flag");
debug("X = %d\n", x);
showlist(The first, second, and third items.);
report(x>y, "x is %d but y is %d", x, y);
```

results in

```
fprintf(stderr, "Flag");
fprintf(stderr, "X = %d\n", x);
puts("The first, second, and third items.");
((x>y) ? puts("x>y") : printf("x is %d but y is %d", x, y));
```

— *end example*]

16.222 Line control [cpp.line]

1 The string literal of a `#line` directive, if present, shall be a character string literal.

2 The *line number* of the current source line is one greater than the number of new-line characters read or introduced in translation phase 1 (2.6) while processing the source file to the current token.

3

A preprocessing directive of the form

`# line` *digit-sequence new-line*

causes the implementation to behave as if the following sequence of source lines begins with a source line that has a line number as specified by the digit sequence (interpreted as a decimal integer). If the digit sequence specifies zero or a number greater than 2147483647, the behavior is undefined.

1

A preprocessing directive of the form

`# line` *digit-sequence* `"` *s-char-sequence*$_{opt}$`"` *new-line*

sets the presumed line number similarly and changes the presumed name of the source file to be the contents of the character string literal.

1

A preprocessing directive of the form

`# line` *pp-tokens new-line*

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after `line` on the directive are processed just as in normal text (each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined; otherwise, the result is processed as appropriate.

16.226 Error directive [cpp.error]

1

A preprocessing directive of the form

`# error` *pp-tokens*$_{opt}$ *new-line*

causes the implementation to produce a diagnostic message that includes the specified sequence of preprocessing tokens, and renders the program ill-formed.

16.228 Pragma directive [cpp.pragma]

1

A preprocessing directive of the form

`# pragma` *pp-tokens*$_{opt}$ *new-line*

causes the implementation to behave in an implementation-defined manner. The behavior might cause translation to fail or cause the translator or the resulting program to behave in a non-conforming manner. Any pragma that is not recognized by the implementation is ignored.

16.237 Null directive [cpp.null]

1 A preprocessing directive of the form

`#` *new-line*

has no effect.

16.238 Predefined macro names [cpp.predefined]

1

The following macro names shall be defined by the implementation:

`__cplusplus`
: The name `__cplusplus` is defined to the value `201402L` when compiling a C++ translation unit.[157]

`__DATE__`
: The date of translation of the source file: a character string literal of the form `"Mmm dd yyyy"`, where the names of the months are the same as those generated by the `asctime` function, and the first character of `dd` is a space character if the value is less than 10. If the date of translation is not available, an implementation-defined valid date shall be supplied.

`__FILE__`
: The presumed name of the current source file (a character string literal).[158]

`__LINE__`
: The presumed line number (within the current source file) of the current source line (an integer literal).[158]

`__STDC_HOSTED__`
: The integer literal `1` if the implementation is a hosted implementation or the integer literal `0` if it is not.

`__TIME__`
: The time of translation of the source file: a character string literal of the form `"hh:mm:ss"` as in the time generated by the `asctime` function. If the time of translation is not available, an implementation-defined valid time shall be supplied.

1

The following macro names are conditionally defined by the implementation:

157) It is intended that future versions of this standard will replace the value of this macro with a greater value. Non-conforming compilers should use a value with at most five decimal digits.
158) The presumed source file name and line number can be changed by the `#line` directive.

`__STDC__`
Whether `__STDC__` is predefined and if so, what its value is, are implementation-defined.

`__STDC_MB_MIGHT_NEQ_WC__`
The integer literal `1`, intended to indicate that, in the encoding for `wchar_t`, a member of the basic character set need not have a code value equal to its value when used as the lone character in an ordinary character literal.

`__STDC_VERSION__`
Whether `__STDC_VERSION__` is predefined and if so, what its value is, are implementation-defined.

`__STDC_ISO_10646__`
An integer literal of the form `yyyymmL` (for example, `199712L`). If this symbol is defined, then every character in the Unicode required set, when stored in an object of type `wchar_t`, has the same value as the short identifier of that character. The *Unicode required set* consists of all the characters that are defined by ISO/IEC 10646, along with all amendments and technical corrigenda as of the specified year and month.

`__STDCPP_STRICT_POINTER_SAFETY__`
Defined, and has the value integer literal 1, if and only if the implementation has strict pointer safety (3.2532.0.1).

`__STDCPP_THREADS__`
Defined, and has the value integer literal 1, if and only if a program can have more than one thread of execution (1.859).

1 The values of the predefined macros (except for `__FILE__` and `__LINE__`) remain constant throughout the translation unit.

2 If any of the pre-defined macro names in this subclause, or the identifier `defined`, is the subject of a `#define` or a `#undef` preprocessing directive, the behavior is undefined. Any other predefined macro names shall begin with a leading underscore followed by an uppercase letter or a second underscore.

16.276 Pragma operator [cpp.pragma.op]

A unary operator expression of the form:

`_Pragma (` *string-literal* `)`

is processed as follows: The string literal is *destringized* by deleting the `L` prefix, if present, deleting the leading and trailing double-quotes, replacing each escape sequence `\"` by a double-quote, and replacing each escape sequence `\\` by a single backslash. The resulting sequence of characters is processed through translation phase 3 to produce preprocessing tokens that are executed as if they were the *pp-tokens* in a pragma directive. The original four preprocessing tokens in the unary operator expression are removed.

[*Example:*

```
#pragma listing on "..\listing.dir"
```

can also be expressed as:

```
_Pragma ( "listing on \"..\\listing.dir\"" )
```

The latter form is processed in the same way whether it appears literally as shown, or results from macro replacement, as in:

```
#define LISTING(x) PRAGMA(listing on #x)
#define PRAGMA(x) _Pragma(#x)

LISTING( ..\listing.dir )
```

— *end example*]

17 Library introduction [library]

17.1 General [library.general]

1 This Clause describes the contents of the *C++ standard library*, how a well-formed C++ program makes use of the library, and how a conforming implementation may provide the entities in the library.

2

The following subclauses describe the definitions (17.9), method of description (17.11), and organization (17.37.1) of the library. Clause 17.37, Clauses 18 through 30, and Annex D specify the contents of the library, as well as library requirements and constraints on both well-formed C++ programs and conforming implementations.

1 Detailed specifications for each of the components in the library are in Clauses 18–30, as shown in Table 13.

Table 13 — Library categories

Clause	Category
18	Language support library
19	Diagnostics library
20	General utilities library
21	Strings library
22	Localization library
23	Containers library
24	Iterators library
25	Algorithms library
26	Numerics library
27	Input/output library
28	Regular expressions library
29	Atomic operations library
30	Thread support library

2 The language support library (Clause 18) provides components that are required by certain parts of the C++ language, such as memory allocation (5.2221.1, 5.2455.1) and exception processing (Clause 15).

3 The diagnostics library (Clause 19) provides a consistent framework for reporting errors in a C++ program, including predefined exception classes.

4 The general utilities library (Clause 20) includes components used by other library elements, such as a predefined storage allocator for dynamic storage management (3.2331.1), and components used as infrastructure in C++ programs, such as a tuples, function wrappers, and time facilities.

5 The strings library (Clause 21) provides support for manipulating text represented as sequences of type `char`, sequences of type `char16_t`, sequences of type `char32_t`, sequences of type `wchar_t`, and sequences of any other character-like type.

6 The localization library (Clause 22) provides extended internationalization support for text processing.

7 The containers (Clause 23), iterators (Clause 24), and algorithms (Clause 25) libraries provide a C++ program with access to a subset of the most widely used algorithms and data structures.

8 The numerics library (Clause 26) provides numeric algorithms and complex number components that extend support for numeric processing. The `valarray` component provides support for n-at-a-time processing, potentially implemented as parallel operations on platforms that support such processing. The random

number component provides facilities for generating pseudo-random numbers.

9 The input/output library (Clause 27) provides the `iostream` components that are the primary mechanism for C++ program input and output. They can be used with other elements of the library, particularly strings, locales, and iterators.

10 The regular expressions library (Clause 28) provides regular expression matching and searching.

11 The atomic operations library (Clause 29) allows more fine-grained concurrent access to shared data than is possible with locks.

12 The thread support library (Clause 30) provides components to create and manage threads, including mutual exclusion and interthread communication.

17.3 The C standard library [library.c]

1

The C++ standard library also makes available the facilities of the C standard library, suitably adjusted to ensure static type safety.

1

The descriptions of many library functions rely on the C standard library for the signatures and semantics of those functions. In all such cases, any use of the `restrict` qualifier shall be omitted.

17.9 Definitions [definitions]

17.9.1 [defns.arbitrary.stream]

arbitrary-positional stream

a stream (described in Clause 27) that can seek to any integral position within the length of the stream

[*Note:* Every arbitrary-positional stream is also a repositional stream. — *end note*]

17.9.2 [defns.block]

block

place a thread in the blocked state

17.9.3 [defns.blocked]

blocked thread

a thread that is waiting for some condition (other than the availability of a processor) to be satisfied before it can continue execution[159]

17.9.4 [defns.character]

character

<Clauses 21, 22, 27, and 28> any object which, when treated sequentially, can represent text

[*Note:* The term does not mean only `char`, `char16_t`, `char32_t`, and `wchar_t` objects, but any value that can be represented by a type that provides the definitions specified in these Clauses. — *end note*]

17.9.5 [defns.character.container]

character container type

a class or a type used to represent a *character*

[*Note:* It is used for one of the template parameters of the string, iostream, and regular expression class templates. A character container type is a POD (3.2955) type. — *end note*]

159) This definition is taken from POSIX.

17.9.6 **[defns.comparison]**

comparison function

an operator function (13.1122) for any of the equality (5.3247) or relational (5.3203) operators

17.9.7 **[defns.component]**

component

a group of library entities directly related as members, parameters, or return types

[*Note:* For example, the class template `basic_string` and the non-member function templates that operate on strings are referred to as the *string component*. — *end note*]

17.9.8 **[defns.deadlock]**

deadlock

one or more threads are unable to continue execution because each is blocked waiting for one or more of the others to satisfy some condition

17.9.9 **[defns.default.behavior.impl]**

default behavior

<implementation> any specific behavior provided by the implementation, within the scope of the *required behavior*

17.9.10 **[defns.default.behavior.func]**

default behavior

<specification> a description of *replacement function* and *handler function* semantics

17.9.11 **[defns.handler]**

handler function

a *non-reserved function* whose definition may be provided by a C++ program

[*Note:* A C++ program may designate a handler function at various points in its execution by supplying a pointer to the function when calling any of the library functions that install handler functions (Clause 18). — *end note*]

17.9.12 **[defns.iostream.templates]**

iostream class templates

templates, defined in Clause 27, that take two template arguments

[*Note:* The arguments are named `charT` and `traits`. The argument `charT` is a character container class, and the argument `traits` is a class which defines additional characteristics and functions of the character type represented by `charT` necessary to implement the iostream class templates. — *end note*]

17.9.13 **[defns.modifier]**

modifier function

a class member function (9.401) other than a constructor, assignment operator, or destructor that alters the state of an object of the class

17.9.14 **[defns.move.constr]**

move construction

direct-initialization of an object of some type with an rvalue of the same type

17.9.15 **[defns.move.assign]**

move assignment

assignment of an rvalue of some object type to a modifiable lvalue of the same type

17.9.16 **[defns.obj.state]**

object state

the current value of all non-static class members of an object (9.194)

[*Note:* The state of an object can be obtained by using one or more *observer functions*. — *end note*]

17.9.17 **[defns.ntcts]**

NTCTS

a sequence of values that have *character type* that precede the terminating null character type value `charT()`

17.9.18 **[defns.observer]**

observer function

a class member function (9.401) that accesses the state of an object of the class but does not alter that state

[*Note:* Observer functions are specified as `const` member functions (9.508.1). — *end note*]

17.9.19 **[defns.referenceable]**

referenceable type

An object type, a function type that does not have cv-qualifiers or a *ref-qualifier*, or a reference type. [*Note:* The term describes a type to which a reference can be created, including reference types. — *end note*]

17.9.20 **[defns.replacement]**

replacement function

a *non-reserved function* whose definition is provided by a C++ program

[*Note:* Only one definition for such a function is in effect for the duration of the program's execution, as the result of creating the program (2.6) and resolving the definitions of all translation units (3.1459). — *end note*]

17.9.21 **[defns.repositional.stream]**

repositional stream

a stream (described in Clause 27) that can seek to a position that was previously encountered

17.9.22 **[defns.required.behavior]**

required behavior

a description of *replacement function* and *handler function* semantics applicable to both the behavior provided by the implementation and the behavior of any such function definition in the program

[*Note:* If such a function defined in a C++ program fails to meet the required behavior when it executes, the behavior is undefined. — *end note*]

17.9.23 **[defns.reserved.function]**

reserved function

a function, specified as part of the C++ standard library, that must be defined by the implementation

[*Note:* If a C++ program provides a definition for any reserved function, the results are undefined. — *end note*]

17.9.24 **[defns.stable]**

stable algorithm

an algorithm that preserves, as appropriate to the particular algorithm, the order of elements

[*Note:* Requirements for stable algorithms are given in 17.602.0.1. — *end note*]

17.9.25 **[defns.traits]**

traits class

a class that encapsulates a set of types and functions necessary for class templates and function templates to manipulate objects of types for which they are instantiated

[*Note:* Traits classes defined in Clauses 21, 22 and 27 are *character traits*, which provide the character handling support needed by the string and iostream classes. — *end note*]

17.9.26 **[defns.unblock]**

unblock

place a thread in the unblocked state

17.9.27 **[defns.valid]**

valid but unspecified state

an object state that is not specified except that the object's invariants are met and operations on the object behave as specified for its type

[*Example:* If an object `x` of type `std::vector<int>` is in a valid but unspecified state, `x.empty()` can be called unconditionally, and `x.front()` can be called only if `x.empty()` returns `false`. — *end example*]

17.10 Additional definitions [defns.additional]

1 1.27 defines additional terms used elsewhere in this International Standard.

17.11 Method of description (Informative) [description]

1 This subclause describes the conventions used to specify the C++ standard library. 17.11.1 describes the structure of the normative Clauses 18 through 30 and Annex D. 17.17.1 describes other editorial conventions.

17.11.1 Structure of each clause [structure]

17.11.1.1 Elements [structure.elements]

1 Each library clause contains the following elements, as applicable:[160]

(1.1) — Summary

(1.2) — Requirements

(1.3) — Detailed specifications

(1.4) — References to the Standard C library

17.11.1.2 Summary [structure.summary]

1 The Summary provides a synopsis of the category, and introduces the first-level subclauses. Each subclause also provides a summary, listing the headers specified in the subclause and the library entities provided in each header.

160) To save space, items that do not apply to a Clause are omitted. For example, if a Clause does not specify any requirements, there will be no "Requirements" subclause.

2

Paragraphs labeled "Note(s):" or "Example(s):" are informative, other paragraphs are normative.

1 The contents of the summary and the detailed specifications include:

(1.1) — macros

(1.2) — values

(1.3) — types

(1.4) — classes and class templates

(1.5) — functions and function templates

(1.6) — objects

17.12.0.1 Requirements [structure.requirements]

1 Requirements describe constraints that shall be met by a C++ program that extends the standard library. Such extensions are generally one of the following:

(1.1) — Template arguments

(1.2) — Derived classes

(1.3) — Containers, iterators, and algorithms that meet an interface convention

2 The string and iostream components use an explicit representation of operations required of template arguments. They use a class template `char_traits` to define these constraints.

3

Interface convention requirements are stated as generally as possible. Instead of stating "class X has to define a member function `operator++()`," the interface requires "for any object `x` of class `X`, `++x` is defined." That is, whether the operator is a member is unspecified.

1 Requirements are stated in terms of well-defined expressions that define valid terms of the types that satisfy the requirements. For every set of well-defined expression requirements there is a table that specifies an initial set of the valid expressions and their semantics. Any generic algorithm (Clause 25) that uses the well-defined expression requirements is described in terms of the valid expressions for its template type parameters.

2 Template argument requirements are sometimes referenced by name. See 17.17.1.1.

3

In some cases the semantic requirements are presented as C++ code. Such code is intended as a specification of equivalence of a construct to another construct, not necessarily as the way the construct must be implemented.[161]

17.14.0.1 Detailed specifications [structure.specifications]

1 The detailed specifications each contain the following elements:

(1.1) — name and brief description

(1.2) — synopsis (class definition or function prototype, as appropriate)

(1.3) — restrictions on template arguments, if any

161) Although in some cases the code given is unambiguously the optimum implementation.

(1.4) — description of class invariants

(1.5) — description of function semantics

2 Descriptions of class member functions follow the order (as appropriate):[162]

(2.1) — constructor(s) and destructor

(2.2) — copying, moving & assignment functions

(2.3) — comparison functions

(2.4) — modifier functions

(2.5) — observer functions

(2.6) — operators and other non-member functions

3 Descriptions of function semantics contain the following elements (as appropriate):[163]

(3.1) — *Requires:* the preconditions for calling the function

(3.2) — *Effects:* the actions performed by the function

(3.3) — *Synchronization:* the synchronization operations (1.859) applicable to the function

(3.4) — *Postconditions:* the observable results established by the function

(3.5) — *Returns:* a description of the value(s) returned by the function

(3.6) — *Throws:* any exceptions thrown by the function, and the conditions that would cause the exception

(3.7) — *Complexity:* the time and/or space complexity of the function

(3.8) — *Remarks:* additional semantic constraints on the function

(3.9) — *Error conditions:* the error conditions for error codes reported by the function.

(3.10) — *Notes:* non-normative comments about the function

4 Whenever the *Effects:* element specifies that the semantics of some function `F` are *Equivalent to* some code sequence, then the various elements are interpreted as follows. If `F`'s semantics specifies a *Requires:* element, then that requirement is logically imposed prior to the *equivalent-to* semantics. Next, the semantics of the code sequence are determined by the *Requires:*, *Effects:*, *Postconditions:*, *Returns:*, *Throws:*, *Complexity:*, *Remarks:*, *Error conditions:*, and *Notes:* specified for the function invocations contained in the code sequence. The value returned from `F` is specified by `F`'s *Returns:* element, or if `F` has no *Returns:* element, a non-`void` return from `F` is specified by the *Returns:* elements in the code sequence. If `F`'s semantics contains a *Throws:*, *Postconditions:*, or *Complexity:* element, then that supersedes any occurrences of that element in the code sequence.

5 For non-reserved replacement and handler functions, Clause 18 specifies two behaviors for the functions in question: their required and default behavior. The *default behavior* describes a function definition provided by the implementation. The *required behavior* describes the semantics of a function definition provided by either the implementation or a C++ program. Where no distinction is explicitly made in the description, the behavior described is the required behavior.

162) To save space, items that do not apply to a class are omitted. For example, if a class does not specify any comparison functions, there will be no "Comparison functions" subclause.

163) To save space, items that do not apply to a function are omitted. For example, if a function does not specify any further preconditions, there will be no "Requires" paragraph.

6 If the formulation of a complexity requirement calls for a negative number of operations, the actual requirement is zero operations.[164]

7

Complexity requirements specified in the library clauses are upper bounds, and implementations that provide better complexity guarantees satisfy the requirements.

1 Error conditions specify conditions where a function may fail. The conditions are listed, together with a suitable explanation, as the `enum class errc` constants (19.14).

17.17.0.1 C library [structure.see.also]

1 Paragraphs labeled "See also:" contain cross-references to the relevant portions of this International Standard and the ISO C standard, which is incorporated into this International Standard by reference.

17.17.1 Other conventions [conventions]

1 This subclause describes several editorial conventions used to describe the contents of the C++ standard library. These conventions are for describing implementation-defined types (17.17.1.1), and member functions (17.28.0.1).

17.17.1.1 Type descriptions [type.descriptions]

17.17.1.1.1 General [type.descriptions.general]

1 The Requirements subclauses may describe names that are used to specify constraints on template arguments.[165] These names are used in library Clauses to describe the types that may be supplied as arguments by a C++ program when instantiating template components from the library.

2 Certain types defined in Clause 27 are used to describe implementation-defined types. They are based on other types, but with added constraints.

17.17.1.1.2 Enumerated types [enumerated.types]

1

Several types defined in Clause 27 are *enumerated types*. Each enumerated type may be implemented as an enumeration or as a synonym for an enumeration.[166]

1

The enumerated type *enumerated* can be written:

```
enum enumerated { V0, V1, V2, V3, ..... };

static const enumerated C0 (V0);
static const enumerated C1 (V1);
static const enumerated C2 (V2);
static const enumerated C3 (V3);
  .....
```

1

Here, the names *C0*, *C1*, etc. represent *enumerated elements* for this particular enumerated type. All such elements have distinct values.

164) This simplifies the presentation of complexity requirements in some cases.
165) Examples from 17.128.1 include: `EqualityComparable`, `LessThanComparable`, `CopyConstructible`. Examples from 24.2 include: `InputIterator`, `ForwardIterator`, `Function`, `Predicate`.
166) Such as an integer type, with constant integer values (3.3151.1).

17.20.0.0.1 Bitmask types [bitmask.types]

1

Several types defined in Clauses 18 through 30 and Annex D are *bitmask types*. Each bitmask type can be implemented as an enumerated type that overloads certain operators, as an integer type, or as a `bitset` (20.68).

1 The bitmask type *bitmask* can be written:

```
// For exposition only.
// int_type is an integral type capable of
// representing all values of the bitmask type.
enum bitmask : int_type {
  V0 = 1 << 0, V1 = 1 << 1, V2 = 1 << 2, V3 = 1 << 3, .....
};

constexpr bitmask C0(V0);
constexpr bitmask C1(V1);
constexpr bitmask C2(V2);
constexpr bitmask C3(V3);
  .....

constexpr bitmask operator&(bitmask X, bitmask Y) {
  return static_cast<bitmask>(
    static_cast<int_type>(X) & static_cast<int_type>(Y));
}
constexpr bitmask operator|(bitmask X, bitmask Y) {
  return static_cast<bitmask>(
    static_cast<int_type>(X) | static_cast<int_type>(Y));
}
constexpr bitmask operator^(bitmask X, bitmask Y){
  return static_cast<bitmask>(
    static_cast<int_type>(X) ^ static_cast<int_type>(Y));
}
constexpr bitmask operator~(bitmask X){
  return static_cast<bitmask>(~static_cast<int_type>(X));
}
bitmask& operator&=(bitmask& X, bitmask Y){
  X = X & Y; return X;
}
bitmask& operator|=(bitmask& X, bitmask Y) {
  X = X | Y; return X;
}
bitmask& operator^=(bitmask& X, bitmask Y) {
  X = X ^ Y; return X;
}
```

2 Here, the names *C0*, *C1*, etc. represent *bitmask elements* for this particular bitmask type. All such elements have distinct, nonzero values such that, for any pair *Ci* and *Cj* where $i \mathrel{!=} j$, *Ci* & *Ci* is nonzero and *Ci* & *Cj* is zero. Additionally, the value 0 is used to represent an *empty bitmask*, in which no bitmask elements are set.

3

The following terms apply to objects and values of bitmask types:

— To *set* a value *Y* in an object *X* is to evaluate the expression *X* `|=` *Y*.

— To *clear* a value Y in an object X is to evaluate the expression X `&= ~` Y.

— The value Y *is set* in the object X if the expression X `&` Y is nonzero.

17.24.0.0.1 Character sequences [character.seq]

1

The C standard library makes widespread use of characters and character sequences that follow a few uniform conventions:

— A *letter* is any of the 26 lowercase or 26 uppercase letters in the basic execution character set.[167]

— The *decimal-point character* is the (single-byte) character used by functions that convert between a (single-byte) character sequence and a value of one of the floating-point types. It is used in the character sequence to denote the beginning of a fractional part. It is represented in Clauses 18 through 30 and Annex D by a period, `'.'`, which is also its value in the `"C"` locale, but may change during program execution by a call to `setlocale(int, const char*)`,[168] or by a change to a `locale` object, as described in Clauses 22.3 and 27.

— A *character sequence* is an array object (8.251.1) A that can be declared as `T A[N]`, where T is any of the types `char`, `unsigned char`, or `signed char` (3.3151.1), optionally qualified by any combination of `const` or `volatile`. The initial elements of the array have defined contents up to and including an element determined by some predicate. A character sequence can be designated by a pointer value S that points to its first element.

17.25.0.0.0.1 Byte strings [byte.strings]

1 A *null-terminated byte string*, or NTBS, is a character sequence whose highest-addressed element with defined content has the value zero (the *terminating null* character); no other element in the sequence has the value zero.[169]

2

The *length* of an NTBS is the number of elements that precede the terminating null character. An *empty* NTBS has a length of zero.

1 The *value* of an NTBS is the sequence of values of the elements up to and including the terminating null character.

2 A *static* NTBS is an NTBS with static storage duration.[170]

17.26.0.0.0.1 Multibyte strings [multibyte.strings]

1

A *null-terminated multibyte string,* or NTMBS, is an NTBS that constitutes a sequence of valid multibyte characters, beginning and ending in the initial shift state.[171]

1 A *static* NTMBS is an NTMBS with static storage duration.

167) Note that this definition differs from the definition in ISO C 7.1.1.
168) declared in `<clocale>` (22.118).
169) Many of the objects manipulated by function signatures declared in `<cstring>` (21.261) are character sequences or NTBSs. The size of some of these character sequences is limited by a length value, maintained separately from the character sequence.
170) A string literal, such as `"abc"`, is a static NTBS.
171) An NTBS that contains characters only from the basic execution character set is also an NTMBS. Each multibyte character then consists of a single byte.

17.28.0.1 Functions within classes [functions.within.classes]

1 For the sake of exposition, Clauses 18 through 30 and Annex D do not describe copy/move constructors, assignment operators, or (non-virtual) destructors with the same apparent semantics as those that can be generated by default (12.30, 12.807, 12.1577).

2 It is unspecified whether the implementation provides explicit definitions for such member function signatures, or for virtual destructors that can be generated by default.

17.28.0.2 Private members [objects.within.classes]

1

Clauses 18 through 30 and Annex D do not specify the representation of classes, and intentionally omit specification of class members (9.194). An implementation may define static or non-static class members, or both, as needed to implement the semantics of the member functions specified in Clauses 18 through 30 and Annex D.

1

Objects of certain classes are sometimes required by the external specifications of their classes to store data, apparently in member objects. For the sake of exposition, some subclauses provide representative declarations, and semantic requirements, for private member objects of classes that meet the external specifications of the classes. The declarations for such member objects and the definitions of related member types are followed by a comment that ends with *exposition only*, as in:

```
streambuf* sb;   // exposition only
```

1

An implementation may use any technique that provides equivalent external behavior.

17.37 Library-wide requirements [requirements]

1 This subclause specifies requirements that apply to the entire C++ standard library. Clauses 18 through 30 and Annex D specify the requirements of individual entities within the library.

2 Requirements specified in terms of interactions between threads do not apply to programs having only a single thread of execution.

3 Within this subclause, 17.37.1 describes the library's contents and organization, 17.109.1 describes how well-formed C++ programs gain access to library entities, 17.128.1 describes constraints on types and functions used with the C++ standard library, 17.194.1 describes constraints on well-formed C++ programs, and 17.544.1 describes constraints on conforming implementations.

17.37.1 Library contents and organization [organization]

1 17.37.1.1 describes the entities defined in the C++ standard library. 17.48.0.1 lists the standard library headers and some constraints on those headers. 17.97.0.1 lists requirements for a freestanding implementation of the C++ standard library.

17.37.1.1 Library contents [contents]

1

The C++ standard library provides definitions for the following types of entities: macros, values, types, templates, classes, functions, objects.

1

All library entities except macros, `operator new` and `operator delete` are defined within the namespace `std` or namespaces nested within namespace `std`.[172] It is unspecified whether names declared in a specific namespace are declared directly in that namespace or in an inline namespace inside that namespace.[173]

1 Whenever a name `x` defined in the standard library is mentioned, the name `x` is assumed to be fully qualified as `::std::x`, unless explicitly described otherwise. For example, if the Effects section for library function `F` is described as calling library function `G`, the function `::std::G` is meant.

17.48.0.1 Headers [headers]

1

Each element of the C++ standard library is declared or defined (as appropriate) in a *header*.[174]

1

The C++ standard library provides 53 *C++ library headers*, as shown in Table 14.

Table 14 — C++ library headers

`<algorithm>`	`<fstream>`	`<list>`	`<regex>`	`<tuple>`
`<array>`	`<functional>`	`<locale>`	`<scoped_allocator>`	`<type_traits>`
`<atomic>`	`<future>`	`<map>`	`<set>`	`<typeindex>`
`<bitset>`	`<initializer_list>`	`<memory>`	`<sstream>`	`<typeinfo>`
`<chrono>`	`<iomanip>`	`<mutex>`	`<stack>`	`<unordered_map>`
`<codecvt>`	`<ios>`	`<new>`	`<stdexcept>`	`<unordered_set>`
`<complex>`	`<iosfwd>`	`<numeric>`	`<streambuf>`	`<utility>`
`<condition_variable>`	`<iostream>`	`<ostream>`	`<string>`	`<valarray>`
`<deque>`	`<istream>`	`<queue>`	`<strstream>`	`<vector>`
`<exception>`	`<iterator>`	`<random>`	`<system_error>`	
`<forward_list>`	`<limits>`	`<ratio>`	`<thread>`	

1

The facilities of the C standard Library are provided in 26 additional headers, as shown in Table 15.

Table 15 — C++ headers for C library facilities

`<cassert>`	`<cinttypes>`	`<csignal>`	`<cstdio>`	`<cwchar>`
`<ccomplex>`	`<ciso646>`	`<cstdalign>`	`<cstdlib>`	`<cwctype>`
`<cctype>`	`<climits>`	`<cstdarg>`	`<cstring>`	
`<cerrno>`	`<clocale>`	`<cstdbool>`	`<ctgmath>`	
`<cfenv>`	`<cmath>`	`<cstddef>`	`<ctime>`	
`<cfloat>`	`<csetjmp>`	`<cstdint>`	`<cuchar>`	

1

Except as noted in Clauses 18 through 30 and Annex D, the contents of each header `c`*`name`* shall be the same as that of the corresponding header *`name`*`.h`, as specified in the C standard library (1.4) or the C Unicode TR, as appropriate, as if by inclusion. In the C++ standard library, however, the declarations (except for

172) The C standard library headers (Annex D.9) also define names within the global namespace, while the C++ headers for C library facilities (17.48.0.1) may also define names within the global namespace.
173) This gives implementers freedom to use inline namespaces to support multiple configurations of the library.
174) A header is not necessarily a source file, nor are the sequences delimited by `<` and `>` in header names necessarily valid source file names (16.48).

names which are defined as macros in C) are within namespace scope (3.736.1) of the namespace `std`. It is unspecified whether these names are first declared within the global namespace scope and are then injected into namespace `std` by explicit *using-declarations* (7.1311.1).

1

Names which are defined as macros in C shall be defined as macros in the C++ standard library, even if C grants license for implementation as functions. [*Note:* The names defined as macros in C include the following: `assert`, `offsetof`, `setjmp`, `va_arg`, `va_end`, and `va_start`. — *end note*]

1

Names that are defined as functions in C shall be defined as functions in the C++ standard library.[175]

1

Identifiers that are keywords or operators in C++ shall not be defined as macros in C++ standard library headers.[176]

1 D.9, C standard library headers, describes the effects of using the *`name`*`.h` (C header) form in a C++ program.[177]

17.97.0.1 Freestanding implementations [compliance]

1

Two kinds of implementations are defined: *hosted* and *freestanding* (1.196). For a hosted implementation, this International Standard describes the set of available headers.

1

A freestanding implementation has an implementation-defined set of headers. This set shall include at least the headers shown in Table 16.

Table 16 — C++ headers for freestanding implementations

Subclause		Header(s)
		`<ciso646>`
18.2	Types	`<cstddef>`
18.41	Implementation properties	`<cfloat>` `<limits>` `<climits>`
18.114	Integer types	`<cstdint>`
18.127	Start and termination	`<cstdlib>`
18.159	Dynamic memory management	`<new>`
18.227	Type identification	`<typeinfo>`
18.241	Exception handling	`<exception>`
18.274	Initializer lists	`<initializer_list>`
18.295	Other runtime support	`<cstdalign>` `<cstdarg>` `<cstdbool>`
20.449	Type traits	`<type_traits>`
29	Atomics	`<atomic>`

1

175) This disallows the practice, allowed in C, of providing a masking macro in addition to the function prototype. The only way to achieve equivalent inline behavior in C++ is to provide a definition as an extern inline function.
176) In particular, including the standard header `<iso646.h>` or `<ciso646>` has no effect.
177) The `".h"` headers dump all their names into the global namespace, whereas the newer forms keep their names in namespace `std`. Therefore, the newer forms are the preferred forms for all uses except for C++ programs which are intended to be strictly compatible with C.

The supplied version of the header `<cstdlib>` shall declare at least the functions `abort`, `atexit`, `at_quick_exit`, `exit`, and `quick_exit` (18.127). The other headers listed in this table shall meet the same requirements as for a hosted implementation.

17.109.1 Using the library [using]

17.109.1.1 Overview [using.overview]

1

This section describes how a C++ program gains access to the facilities of the C++ standard library. 17.110.0.1 describes effects during translation phase 4, while 17.125.0.1 describes effects during phase 8 (2.6).

17.110.0.1 Headers [using.headers]

1 The entities in the C++ standard library are defined in headers, whose contents are made available to a translation unit when it contains the appropriate `#include` preprocessing directive (16.48).

2

A translation unit may include library headers in any order (Clause 2). Each may be included more than once, with no effect different from being included exactly once, except that the effect of including either `<cassert>` or `<assert.h>` depends each time on the lexically current definition of `NDEBUG`.[178]

1

A translation unit shall include a header only outside of any external declaration or definition, and shall include the header lexically before the first reference in that translation unit to any of the entities declared in that header. No diagnostic is required.

17.125.0.1 Linkage [using.linkage]

1

Entities in the C++ standard library have external linkage (3.1459). Unless otherwise specified, objects and functions have the default `extern "C++"` linkage (7.1477).

1

Whether a name from the C standard library declared with external linkage has `extern "C"` or `extern "C++"` linkage is implementation-defined. It is recommended that an implementation use `extern "C++"` linkage for this purpose.[179]

1 Objects and functions defined in the library and required by a C++ program are included in the program prior to program startup.

See also: replacement functions (17.428.0.3), run-time changes (17.436.0.1).

17.128.1 Requirements on types and expressions [utility.requirements]

1 17.128.1.1 describes requirements on types and expressions used to instantiate templates defined in the C++ standard library. 17.143.0.1 describes the requirements on swappable types and swappable expressions. 17.153.0.1 describes the requirements on pointer-like types that support null values. 17.159.0.1 describes the requirements on hash function objects. 17.165.0.1 describes the requirements on storage allocators.

17.128.1.1 Template argument requirements [utility.arg.requirements]

1

178) This is the same as the Standard C library.

179) The only reliable way to declare an object or function signature from the Standard C library is by including the header that declares it, notwithstanding the latitude granted in 7.1.4 of the C Standard.

The template definitions in the C++ standard library refer to various named requirements whose details are set out in tables 17–24. In these tables, `T` is an object or reference type to be supplied by a C++ program instantiating a template; `a`, `b`, and `c` are values of type (possibly `const`) `T`; `s` and `t` are modifiable lvalues of type `T`; `u` denotes an identifier; `rv` is an rvalue of type `T`; and `v` is an lvalue of type (possibly `const`) `T` or an rvalue of type `const T`.

1

In general, a default constructor is not required. Certain container class member function signatures specify `T()` as a default argument. `T()` shall be a well-defined expression (8.821) if one of those signatures is called using the default argument (8.545.1).

Table 17 — `EqualityComparable` requirements [**equalitycomparable**]

Expression	Return type	Requirement
`a == b`	convertible to `bool`	`==` is an equivalence relation, that is, it has the following properties: — For all `a`, `a == a`. — If `a == b`, then `b == a`. — If `a == b` and `b == c`, then `a == c`.

Table 18 — `LessThanComparable` requirements [**lessthancomparable**]

Expression	Return type	Requirement
`a < b`	convertible to `bool`	`<` is a strict weak ordering relation (25.98)

Table 19 — `DefaultConstructible` requirements [**defaultconstructible**]

Expression	Post-condition
`T t;`	object `t` is default-initialized
`T u{};`	object `u` is value-initialized
`T()` `T{}`	a temporary object of type `T` is value-initialized

Table 20 — `MoveConstructible` requirements [**moveconstructible**]

Expression	Post-condition
`T u = rv;`	`u` is equivalent to the value of `rv` before the construction
`T(rv)`	`T(rv)` is equivalent to the value of `rv` before the construction
`rv`'s state is unspecified [*Note:* `rv` must still meet the requirements of the library component that is using it. The operations listed in those requirements must work as specified whether `rv` has been moved from or not. — *end note*]	

Table 21 — `CopyConstructible` requirements (in addition to `MoveConstructible`) [**copyconstructible**]

Expression	Post-condition
`T u = v;`	the value of `v` is unchanged and is equivalent to `u`
`T(v)`	the value of `v` is unchanged and is equivalent to `T(v)`

Table 22 — `MoveAssignable` requirements [**moveassignable**]

Expression	Return type	Return value	Post-condition
`t = rv`	`T&`	`t`	`t` is equivalent to the value of `rv` before the assignment
`rv`'s state is unspecified. [*Note:* `rv` must still meet the requirements of the library component that is using it. The operations listed in those requirements must work as specified whether `rv` has been moved from or not. — *end note*]			

Table 23 — `CopyAssignable` requirements (in addition to `MoveAssignable`) [**copyassignable**]

Expression	Return type	Return value	Post-condition
`t = v`	`T&`	`t`	`t` is equivalent to `v`, the value of `v` is unchanged

Table 24 — `Destructible` requirements [**destructible**]

Expression	Post-condition
`u.~T()`	All resources owned by `u` are reclaimed, no exception is propagated.

17.143.0.1 `Swappable` requirements [**swappable.requirements**]

1 This subclause provides definitions for swappable types and expressions. In these definitions, let `t` denote an expression of type `T`, and let `u` denote an expression of type `U`.

2 An object `t` is *swappable with* an object `u` if and only if:

(2.1) — the expressions `swap(t, u)` and `swap(u, t)` are valid when evaluated in the context described below, and

(2.2) — these expressions have the following effects:

(2.2.1) — the object referred to by `t` has the value originally held by `u` and

(2.2.2) — the object referred to by `u` has the value originally held by `t`.

3

The context in which `swap(t, u)` and `swap(u, t)` are evaluated shall ensure that a binary non-member function named "swap" is selected via overload resolution (13.88) on a candidate set that includes:

— the two `swap` function templates defined in `<utility>` (20.2) and

— the lookup set produced by argument-dependent lookup (3.1092.1).

[*Note:* If `T` and `U` are both fundamental types or arrays of fundamental types and the declarations from the header `<utility>` are in scope, the overall lookup set described above is equivalent to that of the qualified name lookup applied to the expression `std::swap(t, u)` or `std::swap(u, t)` as appropriate. — *end note*]

[*Note:* It is unspecified whether a library component that has a swappable requirement includes the header `<utility>` to ensure an appropriate evaluation context. — *end note*]

1

An rvalue or lvalue `t` is *swappable* if and only if `t` is swappable with any rvalue or lvalue, respectively, of type `T`.

1 A type `X` satisfying any of the iterator requirements (24.2) satisfies the requirements of `ValueSwappable` if, for any dereferenceable object `x` of type `X`, `*x` is swappable.

[*Example:* User code can ensure that the evaluation of `swap` calls is performed in an appropriate context under the various conditions as follows:

```
#include <utility>

// Requires: std::forward<T>(t) shall be swappable with std::forward<U>(u).
template <class T, class U>
void value_swap(T&& t, U&& u) {
  using std::swap;
  swap(std::forward<T>(t), std::forward<U>(u)); // OK: uses "swappable with" conditions
                                                // for rvalues and lvalues
}

// Requires: lvalues of T shall be swappable.
template <class T>
void lv_swap(T& t1 T& t2) {
  using std::swap;
  swap(t1, t2);                                 // OK: uses swappable conditions for
}                                               // lvalues of type T

namespace N {
  struct A { int m; };
  struct Proxy { A* a; };
  Proxy proxy(A& a) { return Proxy{ &a }; }

  void swap(A& x, Proxy p) {
    std::swap(x.m, p.a->m);                     // OK: uses context equivalent to swappable
                                                // conditions for fundamental types
  }
  void swap(Proxy p, A& x) { swap(x, p); }      // satisfy symmetry constraint
}

int main() {
  int i = 1, j = 2;
  lv_swap(i, j);
  assert(i == 2 && j == 1);

  N::A a1 = { 5 }, a2 = { -5 };
  value_swap(a1, proxy(a2));
  assert(a1.m == -5 && a2.m == 5);
}
```

— *end example*]

17.153.0.1 `NullablePointer` requirements [nullablepointer.requirements]

1

A `NullablePointer` type is a pointer-like type that supports null values. A type `P` meets the requirements of `NullablePointer` if:

— `P` satisfies the requirements of `EqualityComparable`, `DefaultConstructible`, `CopyConstructible`, `CopyAssignable`, and `Destructible`,

— lvalues of type `P` are swappable (17.143.0.1),

— the expressions shown in Table 25 are valid and have the indicated semantics, and

— `P` satisfies all the other requirements of this subclause.

1

A value-initialized object of type `P` produces the null value of the type. The null value shall be equivalent only to itself. A default-initialized object of type `P` may have an indeterminate value. [*Note:* Operations involving indeterminate values may cause undefined behavior. — *end note*]

1

An object `p` of type `P` can be contextually converted to `bool` (Clause 4). The effect shall be as if `p != nullptr` had been evaluated in place of `p`.

1 No operation which is part of the `NullablePointer` requirements shall exit via an exception.

2

In Table 25, `u` denotes an identifier, `t` denotes a non-`const` lvalue of type `P`, `a` and `b` denote values of type (possibly `const`) `P`, and `np` denotes a value of type (possibly `const`) `std::nullptr_t`.

Table 25 — `NullablePointer` requirements **[nullablepointer]**

Expression	Return type	Operational semantics
`P u(np);` `P u = np;`		post: `u == nullptr`
`P(np)`		post: `P(np) == nullptr`
`t = np`	`P&`	post: `t == nullptr`
`a != b`	contextually convertible to `bool`	`!(a == b)`
`a == np` `np == a`	contextually convertible to `bool`	`a == P()`
`a != np` `np != a`	contextually convertible to `bool`	`!(a == np)`

17.159.0.1 Hash requirements [hash.requirements]

1 A type `H` meets the `Hash` requirements if:

(1.1) — it is a function object type (20.283),

(1.2) — it satisfies the requirements of `CopyConstructible` and `Destructible` (17.128.1.1), and

(1.3) — the expressions shown in Table 26 are valid and have the indicated semantics.

2

Given `Key` is an argument type for function objects of type `H`, in Table 26 `h` is a value of type (possibly `const`) `H`, `u` is an lvalue of type `Key`, and `k` is a value of a type convertible to (possibly `const`) `Key`.

Table 26 — `Hash` requirements **[hash]**

Expression	Return type	Requirement
`h(k)`	`size_t`	The value returned shall depend only on the argument `k` for the duration of the program. [*Note:* Thus all evaluations of the expression `h(k)` with the same value for `k` yield the same result for a given execution of the program. — *end note*] [*Note:* For two different values `t1` and `t2`, the probability that `h(t1)` and `h(t2)` compare equal should be very small, approaching `1.0 / numeric_limits<size_t>::max()`. — *end note*]
`h(u)`	`size_t`	Shall not modify `u`.

17.165.0.1 Allocator requirements [allocator.requirements]

1 The library describes a standard set of requirements for *allocators*, which are class-type objects that encapsulate the information about an allocation model. This information includes the knowledge of pointer types, the type of their difference, the type of the size of objects in this allocation model, as well as the memory allocation and deallocation primitives for it. All of the string types (Clause 21), containers (Clause 23) (except array), string buffers and string streams (Clause 27), and `match_results` (Clause 28) are parameterized in terms of allocators.

2

The template struct `allocator_traits` (20.86.3) supplies a uniform interface to all allocator types. Table 27 describes the types manipulated through allocators. Table 28 describes the requirements on allocator types and thus on types used to instantiate `allocator_traits`. A requirement is optional if the last column of Table 28 specifies a default for a given expression. Within the standard library `allocator_traits` template, an optional requirement that is not supplied by an allocator is replaced by the specified default expression. A user specialization of `allocator_traits` may provide different defaults and may provide defaults for different requirements than the primary template. Within Tables 27 and 28, the use of `move` and `forward` always refers to `std::move` and `std::forward`, respectively.

Table 27 — Descriptive variable definitions

Variable	Definition
`T, U, C`	any non-const object type (3.2955)
`V`	a type convertible to `T`
`X`	an Allocator class for type `T`
`Y`	the corresponding Allocator class for type `U`
`XX`	the type `allocator_traits<X>`
`YY`	the type `allocator_traits<Y>`
`t`	a value of type `const T&`
`a, a1, a2`	values of type `X&`
`a3`	an rvalue of type `X`
`b`	a value of type `Y`
`c`	a pointer of type `C*` through which indirection is valid
`p`	a value of type `XX::pointer`, obtained by calling `a1.allocate`, where `a1 == a`
`q`	a value of type `XX::const_pointer` obtained by conversion from a value `p`.

Table 27 — Descriptive variable definitions (continued)

Variable	Definition
w	a value of type XX::void_pointer obtained by conversion from a value p
z	a value of type XX::const_void_pointer obtained by conversion from a value q or a value w
r	a value of type T& obtained by the expression *p.
s	a value of type const T& obtained by the expression *q or by conversion from a value r.
u	a value of type XX:const_void_pointer obtained by conversion from a result value of YY::allocate, or else a value of type (possibly const) std::nullptr_t.
v	a value of type V
n	a value of type XX::size_type.
Args	a template parameter pack
args	a function parameter pack with the pattern Args&&

Table 28 — Allocator requirements

Expression	Return type	Assertion/note pre-/post-condition	Default
X::pointer			T*
X::const_pointer		X::pointer is convertible to X::const_pointer	pointer_traits<X::pointer>::rebind<const T>
X::void_pointer Y::void_pointer		X::pointer is convertible to X::void_pointer. X::void_pointer and Y::void_pointer are the same type.	pointer_traits<X::pointer>::rebind<void>
X::const_void_pointer Y::const_void_pointer		X::pointer, X::const_pointer, and X::void_pointer are convertible to X::const_void_pointer. X::const_void_pointer and Y::const_void_pointer are the same type.	pointer_traits<X::pointer>::rebind<const void>
X::value_type	Identical to T		
X::size_type	unsigned integer type	a type that can represent the size of the largest object in the allocation model.	make_unsigned_t<X::difference_type>

Table 28 — Allocator requirements (continued)

Expression	Return type	Assertion/note pre-/post-condition	Default
`X::difference_type`	signed integer type	a type that can represent the difference between any two pointers in the allocation model.	`pointer_traits<X::pointer>::difference_type`
`typename X::template rebind<U>::other`	`Y`	For all `U` (including `T`), `Y::template rebind<T>::other` is `X`.	See Note A, below.
`*p`	`T&`		
`*q`	`const T&`	`*q` refers to the same object as `*p`	
`p->m`	type of `T::m`	*pre:* `(*p).m` is well-defined. equivalent to `(*p).m`	
`q->m`	type of `T::m`	*pre:* `(*q).m` is well-defined. equivalent to `(*q).m`	
`static_cast<X::pointer>(w)`	`X::pointer`	`static_cast<X::pointer>(w) == p`	
`static_cast<X::const_pointer>(z)`	`X::const_pointer`	`static_cast<X::const_pointer>(z) == q`	
`a.allocate(n)`	`X::pointer`	Memory is allocated for `n` objects of type `T` but objects are not constructed. `allocate` may raise an appropriate exception.[180] [*Note:* If `n == 0`, the return value is unspecified. — *end note*]	
`a.allocate(n, u)`	`X::pointer`	Same as `a.allocate(n)`. The use of `u` is unspecified, but it is intended as an aid to locality.	`a.allocate(n)`
`a.deallocate(p,n)`	(not used)	All `n T` objects in the area pointed to by `p` shall be destroyed prior to this call. `n` shall match the value passed to `allocate` to obtain this memory. Does not throw exceptions. [*Note:* `p` shall not be singular. — *end note*]	
`a.max_size()`	`X::size_type`	the largest value that can meaningfully be passed to `X::allocate()`	`numeric_limits<size_type>::max()`
`a1 == a2`	`bool`	returns `true` only if storage allocated from each can be deallocated via the other. `operator==` shall be reflexive, symmetric, and transitive, and shall not exit via an exception.	

Table 28 — Allocator requirements (continued)

Expression	Return type	Assertion/note pre-/post-condition	Default
`a1 != a2`	`bool`	same as `!(a1 == a2)`	
`a == b`	`bool`	same as `a == Y::rebind<T>::other(b)`	
`a != b`	`bool`	same as `!(a == b)`	
`X a1(a);` `X a1 = a;`		Shall not exit via an exception. post: `a1 == a`	
`X a(b);`		Shall not exit via an exception. post: `Y(a) == b`, `a == X(b)`	
`X a1(move(a));` `X a1 = move(a);`		Shall not exit via an exception. post: `a1` equals the prior value of `a`.	
`X a(move(b));`		Shall not exit via an exception. post: `a` equals the prior value of `X(b)`.	
`a.construct(c, args)`	(not used)	Effect: Constructs an object of type `C` at `c`	`::new ((void*)c) C(forward< Args> (args)...)`
`a.destroy(c)`	(not used)	Effect: Destroys the object at `c`	`c->~C()`
`a.select_on_container_copy_construction()`	`X`	Typically returns either `a` or `X()`	`return a;`
`X::propagate_on_container_copy_assignment`	Identical to or derived from `true_type` or `false_type`	`true_type` only if an allocator of type `X` should be copied when the client container is copy-assigned.	`false_type`
`X::propagate_on_container_move_assignment`	Identical to or derived from `true_type` or `false_type`	`true_type` only if an allocator of type `X` should be moved when the client container is move-assigned.	`false_type`
`X::propagate_on_container_swap`	Identical to or derived from `true_type` or `false_type`	`true_type` only if an allocator of type `X` should be swapped when the client container is swapped.	`false_type`

1

Note A: The member class template `rebind` in the table above is effectively a typedef template. [*Note:* In general, if the name `Allocator` is bound to `SomeAllocator<T>`, then `Allocator::rebind<U>::other` is the same type as `SomeAllocator<U>`, where `SomeAllocator<T>::value_type` is `T` and `SomeAllocator<U>::value_type` is `U`. — *end note*] If `Allocator` is a class template instantiation of the form `SomeAllocator<T, Args>`, where `Args` is zero or more type arguments, and `Allocator` does not supply a `rebind` member template, the standard `allocator_traits` template uses `SomeAllocator<U, Args>` in place of `Allocator::`

180) It is intended that `a.allocate` be an efficient means of allocating a single object of type `T`, even when `sizeof(T)` is small. That is, there is no need for a container to maintain its own free list.

`rebind<U>::other` by default. For allocator types that are not template instantiations of the above form, no default is provided.

1

An allocator type `X` shall satisfy the requirements of `CopyConstructible` (17.128.1.1). The `X::pointer`, `X::const_pointer`, `X::void_pointer`, and `X::const_void_pointer` types shall satisfy the requirements of `NullablePointer` (17.153.0.1). No constructor, comparison operator, copy operation, move operation, or swap operation on these types shall exit via an exception. `X::pointer` and `X::const_pointer` shall also satisfy the requirements for a random access iterator (24.2).

1 Let `x1` and `x2` denote objects of (possibly different) types `X::void_pointer`, `X::const_void_pointer`, `X::pointer`, or `X::const_pointer`. Then, `x1` and `x2` are *equivalently-valued* pointer values, if and only if both `x1` and `x2` can be explicitly converted to the two corresponding objects `px1` and `px2` of type `X::const_pointer`, using a sequence of `static_cast`s using only these four types, and the expression `px1 == px2` evaluates to `true`.

2 Let `w1` and `w2` denote objects of type `X::void_pointer`. Then for the expressions

```
w1 == w2
w1 != w2
```

either or both objects may be replaced by an equivalently-valued object of type `X::const_void_pointer` with no change in semantics.

3 Let `p1` and `p2` denote objects of type `X::pointer`. Then for the expressions

```
p1 == p2
p1 != p2
p1 < p2
p1 <= p2
p1 >= p2
p1 > p2
p1 - p2
```

either or both objects may be replaced by an equivalently-valued object of type `X::const_pointer` with no change in semantics.

4

An allocator may constrain the types on which it can be instantiated and the arguments for which its `construct` member may be called. If a type cannot be used with a particular allocator, the allocator class or the call to `construct` may fail to instantiate.

[*Example:* the following is an allocator class template supporting the minimal interface that satisfies the requirements of Table 28:

```
template <class Tp>
struct SimpleAllocator {
  typedef Tp value_type;
  SimpleAllocator(ctor args);

  template <class T> SimpleAllocator(const SimpleAllocator<T>& other);

  Tp* allocate(std::size_t n);
  void deallocate(Tp* p, std::size_t n);
};

template <class T, class U>
bool operator==(const SimpleAllocator<T>&, const SimpleAllocator<U>&);
```

```
template <class T, class U>
bool operator!=(const SimpleAllocator<T>&, const SimpleAllocator<U>&);
```

— *end example*]

1

If the alignment associated with a specific over-aligned type is not supported by an allocator, instantiation of the allocator for that type may fail. The allocator also may silently ignore the requested alignment. [*Note:* Additionally, the member function `allocate` for that type may fail by throwing an object of type `std::bad_alloc`. — *end note*]

17.194.1 Constraints on programs [constraints]

17.194.1.1 Overview [constraints.overview]

1

This section describes restrictions on C++ programs that use the facilities of the C++ standard library. The following subclauses specify constraints on the program's use of namespaces (17.198.0.1.1), its use of various reserved names (17.296.0.1), its use of headers (17.428.0.1), its use of standard library classes as base classes (17.428.0.2), its definitions of replacement functions (17.428.0.3), and its installation of handler functions during execution (17.436.0.1).

17.198.0.1 Namespace use [namespace.constraints]

17.198.0.1.1 Namespace `std` [namespace.std]

1

The behavior of a C++ program is undefined if it adds declarations or definitions to namespace `std` or to a namespace within namespace `std` unless otherwise specified. A program may add a template specialization for any standard library template to namespace `std` only if the declaration depends on a user-defined type and the specialization meets the standard library requirements for the original template and is not explicitly prohibited.[181]

1

The behavior of a C++ program is undefined if it declares

— an explicit specialization of any member function of a standard library class template, or

— an explicit specialization of any member function template of a standard library class or class template, or

— an explicit or partial specialization of any member class template of a standard library class or class template.

A program may explicitly instantiate a template defined in the standard library only if the declaration depends on the name of a user-defined type and the instantiation meets the standard library requirements for the original template.

1 A translation unit shall not declare namespace `std` to be an inline namespace (7.1149.1).

17.295.0.0.1 Namespace `posix` [namespace.posix]

1

181) Any library code that instantiates other library templates must be prepared to work adequately with any user-supplied specialization that meets the minimum requirements of the Standard.

The behavior of a C++ program is undefined if it adds declarations or definitions to namespace `posix` or to a namespace within namespace `posix` unless otherwise specified. The namespace `posix` is reserved for use by ISO/IEC 9945 and other POSIX standards.

17.296.0.1 Reserved names [reserved.names]

1

The C++ standard library reserves the following kinds of names:

— macros

— global names

— names with external linkage

1

If a program declares or defines a name in a context where it is reserved, other than as explicitly allowed by this Clause, its behavior is undefined.

17.309.0.0.1 Macro names [macro.names]

1

A translation unit that includes a standard library header shall not `#define` or `#undef` names declared in any standard library header.

1

A translation unit shall not `#define` or `#undef` names lexically identical to keywords, to the identifiers listed in Table 3, or to the *attribute-tokens* described in 7.1546.

17.332.0.0.1 Global names [global.names]

1

Certain sets of names and function signatures are always reserved to the implementation:

— Each name that contains a double underscore `__` or begins with an underscore followed by an uppercase letter (2.287) is reserved to the implementation for any use.

— Each name that begins with an underscore is reserved to the implementation for use as a name in the global namespace.

17.405.0.0.1 External linkage [extern.names]

1

Each name declared as an object with external linkage in a header is reserved to the implementation to designate that library object with external linkage,[182] both in namespace `std` and in the global namespace.

1 Each global function signature declared with external linkage in a header is reserved to the implementation to designate that function signature with external linkage. [183]

2

Each name from the Standard C library declared with external linkage is reserved to the implementation for use as a name with `extern "C"` linkage, both in namespace std and in the global namespace.

182) The list of such reserved names includes `errno`, declared or defined in `<cerrno>`.

183) The list of such reserved function signatures with external linkage includes `setjmp(jmp_buf)`, declared or defined in `<csetjmp>`, and `va_end(va_list)`, declared or defined in `<cstdarg>`.

1

Each function signature from the Standard C library declared with external linkage is reserved to the implementation for use as a function signature with both `extern "C"` and `extern "C++"` linkage, [184] or as a name of namespace scope in the global namespace.

17.420.0.0.1 Types [extern.types]

1

For each type T from the Standard C library,[185] the types `::T` and `std::T` are reserved to the implementation and, when defined, `::T` shall be identical to `std::T`.

17.424.0.0.1 User-defined literal suffixes [usrlit.suffix]

1

Literal suffix identifiers that do not start with an underscore are reserved for future standardization.

17.428.0.1 Headers [alt.headers]

1 If a file with a name equivalent to the derived file name for one of the C++ standard library headers is not provided as part of the implementation, and a file with that name is placed in any of the standard places for a source file to be included (16.48), the behavior is undefined.

17.428.0.2 Derived classes [derived.classes]

1 Virtual member function signatures defined for a base class in the C++ standard library may be overridden in a derived class defined in the program (10.113).

17.428.0.3 Replacement functions [replacement.functions]

1

Clauses 18 through 30 and Annex D describe the behavior of numerous functions defined by the C++ standard library. Under some circumstances, however, certain of these function descriptions also apply to replacement functions defined in the program (17.9).

1

A C++ program may provide the definition for any of twelve dynamic memory allocation function signatures declared in header `<new>` (3.2331.1, 18.159):

— `operator new(std::size_t)`

— `operator new(std::size_t, const std::nothrow_t&)`

— `operator new[](std::size_t)`

— `operator new[](std::size_t, const std::nothrow_t&)`

— `operator delete(void*)`

— `operator delete(void*, const std::nothrow_t&)`

— `operator delete[](void*)`

— `operator delete[](void*, const std::nothrow_t&)`

184) The function signatures declared in `<cuchar>`, `<cwchar>`, and `<cwctype>` are always reserved, notwithstanding the restrictions imposed in subclause 4.5.1 of Amendment 1 to the C Standard for these headers.

185) These types are `clock_t`, `div_t`, `FILE`, `fpos_t`, `lconv`, `ldiv_t`, `mbstate_t`, `ptrdiff_t`, `sig_atomic_t`, `size_t`, `time_t`, `tm`, `va_list`, `wctrans_t`, `wctype_t`, and `wint_t`.

— `operator delete(void*, std::size_t)`

— `operator delete(void*, std::size_t, const std::nothrow_t&)`

— `operator delete[](void*, std::size_t)`

— `operator delete[](void*, std::size_t, const std::nothrow_t&)`

1

The program's definitions are used instead of the default versions supplied by the implementation (18.159). Such replacement occurs prior to program startup (3.91, 3.1721). The program's definitions shall not be specified as `inline`. No diagnostic is required.

17.436.0.1 Handler functions [handler.functions]

1 The C++ standard library provides default versions of the following handler functions (Clause 18):

(1.1) — `unexpected_handler`

(1.2) — `terminate_handler`

2

A C++ program may install different handler functions during execution, by supplying a pointer to a function defined in the program or the library as an argument to (respectively):

— `set_new_handler`

— `set_unexpected`

— `set_terminate`

SEE ALSO: subclauses 18.223.1, Storage allocation errors, and 18.241, Exception handling.

1 A C++ program can get a pointer to the current handler function by calling the following functions:

(1.1) — `get_new_handler`

(1.2) — `get_unexpected`

(1.3) — `get_terminate`

2

Calling the `set_*` and `get_*` functions shall not incur a data race. A call to any of the `set_*` functions shall synchronize with subsequent calls to the same `set_*` function and to the corresponding `get_*` function.

17.438.0.1 Other functions [res.on.functions]

1

In certain cases (replacement functions, handler functions, operations on types used to instantiate standard library template components), the C++ standard library depends on components supplied by a C++ program. If these components do not meet their requirements, the Standard places no requirements on the implementation.

1

In particular, the effects are undefined in the following cases:

— for replacement functions (18.159.1), if the installed replacement function does not implement the semantics of the applicable *Required behavior:* paragraph.

— for handler functions (18.226.0.1, 18.247.2.1, D.62.1), if the installed handler function does not implement the semantics of the applicable *Required behavior:* paragraph

— for types used as template arguments when instantiating a template component, if the operations on the type do not implement the semantics of the applicable **Requirements** subclause (17.165.0.1, 23.2, 24.2, 26.2). Operations on such types can report a failure by throwing an exception unless otherwise specified.

— if any replacement function or handler function or destructor operation exits via an exception, unless specifically allowed in the applicable *Required behavior:* paragraph.

— if an incomplete type (3.2955) is used as a template argument when instantiating a template component, unless specifically allowed for that component.

17.513.0.1 Function arguments [res.on.arguments]

1

Each of the following applies to all arguments to functions defined in the C++ standard library, unless explicitly stated otherwise.

— If an argument to a function has an invalid value (such as a value outside the domain of the function or a pointer invalid for its intended use), the behavior is undefined.

— If a function argument is described as being an array, the pointer actually passed to the function shall have a value such that all address computations and accesses to objects (that would be valid if the pointer did point to the first element of such an array) are in fact valid.

— If a function argument binds to an rvalue reference parameter, the implementation may assume that this parameter is a unique reference to this argument. [*Note:* If the parameter is a generic parameter of the form `T&&` and an lvalue of type `A` is bound, the argument binds to an lvalue reference (14.2261.0.1) and thus is not covered by the previous sentence. — *end note*] [*Note:* If a program casts an lvalue to an xvalue while passing that lvalue to a library function (e.g. by calling the function with the argument `move(x)`), the program is effectively asking that function to treat that lvalue as a temporary. The implementation is free to optimize away aliasing checks which might be needed if the argument was an lvalue. — *end note*]

17.535.0.1 Shared objects and the library [res.on.objects]

1

The behavior of a program is undefined if calls to standard library functions from different threads may introduce a data race. The conditions under which this may occur are specified in 17.607.0.1. [*Note:* Modifying an object of a standard library type that is shared between threads risks undefined behavior unless objects of that type are explicitly specified as being sharable without data races or the user supplies a locking mechanism. — *end note*]

1 [*Note:* In particular, the program is required to ensure that completion of the constructor of any object of a class type defined in the standard library happens before any other member function invocation on that object and, unless otherwise specified, to ensure that completion of any member function invocation other than destruction on such an object happens before destruction of that object. This applies even to objects such as mutexes intended for thread synchronization. — *end note*]

17.539.0.1 Requires paragraph [res.on.required]

1

Violation of the preconditions specified in a function's *Requires:* paragraph results in undefined behavior unless the function's *Throws:* paragraph specifies throwing an exception when the precondition is violated.

17.544.1 Conforming implementations [conforming]

17.544.1.1 Overview [conforming.overview]

1 This section describes the constraints upon, and latitude of, implementations of the C++ standard library.

2 An implementation's use of headers is discussed in 17.544.1.2, its use of macros in 17.563.0.1, global functions in 17.565.0.1, member functions in 17.568.0.1, data race avoidance in 17.607.0.1, access specifiers in 17.674.0.1, class derivation in 17.674.0.2, and exceptions in 17.677.0.1.

17.544.1.2 Headers [res.on.headers]

1

A C++ header may include other C++ headers. A C++ header shall provide the declarations and definitions that appear in its synopsis. A C++ header shown in its synopsis as including other C++ headers shall provide the declarations and definitions that appear in the synopses of those other headers.

1

Certain types and macros are defined in more than one header. Every such entity shall be defined such that any header that defines it may be included after any other header that also defines it (3.91).

1

The C standard headers (D.9) shall include only their corresponding C++ standard header, as described in 17.48.0.1.

17.563.0.1 Restrictions on macro definitions [res.on.macro.definitions]

1 The names and global function signatures described in 17.37.1.1 are reserved to the implementation.

2

All object-like macros defined by the C standard library and described in this Clause as expanding to integral constant expressions are also suitable for use in `#if` preprocessing directives, unless explicitly stated otherwise.

17.565.0.1 Global and non-member functions [global.functions]

1

It is unspecified whether any global or non-member functions in the C++ standard library are defined as `inline` (7.94.1).

1 A call to a global or non-member function signature described in Clauses 18 through 30 and Annex D shall behave as if the implementation declared no additional global or non-member function signatures.[186]

2

An implementation shall not declare a global or non-member function signature with additional default arguments.

1

Unless otherwise specified, global and non-member functions in the standard library shall not use functions from another namespace which are found through *argument-dependent name lookup* (3.1092.1). [*Note:* The phrase "unless otherwise specified" is intended to allow argument-dependent lookup in cases like that of `ostream_iterator::operator=` (24.219.0.2):

Effects:

```
*out_stream << value;
```

186) A valid C++ program always calls the expected library global or non-member function. An implementation may also define additional global or non-member functions that would otherwise not be called by a valid C++ program.

```
if (delim != 0)
  *out_stream << delim;
return *this;
```

— *end note*]

17.568.0.1 Member functions [member.functions]

1

It is unspecified whether any member functions in the C++ standard library are defined as `inline` (7.94.1).

1

An implementation may declare additional non-virtual member function signatures within a class:

— by adding arguments with default values to a member function signature;[187] [*Note:* An implementation may not add arguments with default values to virtual, global, or non-member functions. — *end note*]

— by replacing a member function signature with default values by two or more member function signatures with equivalent behavior; and

— by adding a member function signature for a member function name.

1

A call to a member function signature described in the C++ standard library behaves as if the implementation declares no additional member function signatures.[188]

17.598.0.1 `constexpr` functions and constructors [constexpr.functions]

1

This standard explicitly requires that certain standard library functions are `constexpr` (7.328.1). An implementation shall not declare any standard library function signature as `constexpr` except for those where it is explicitly required. Within any header that provides any non-defining declarations of `constexpr` functions or constructors an implementation shall provide corresponding definitions.

17.602.0.1 Requirements for stable algorithms [algorithm.stable]

1

When the requirements for an algorithm state that it is "stable" without further elaboration, it means:

— For the *sort* algorithms the relative order of equivalent elements is preserved.

— For the *remove* and *copy* algorithms the relative order of the elements that are not removed is preserved.

— For the *merge* algorithms, for equivalent elements in the original two ranges, the elements from the first range (preserving their original order) precede the elements from the second range (preserving their original order).

17.604.0.1 Reentrancy [reentrancy]

1

Except where explicitly specified in this standard, it is implementation-defined which functions in the Standard C++ library may be recursively reentered.

187) Hence, the address of a member function of a class in the C++ standard library has an unspecified type.

188) A valid C++ program always calls the expected library member function, or one with equivalent behavior. An implementation may also define additional member functions that would otherwise not be called by a valid C++ program.

17.607.0.1 Data race avoidance [res.on.data.races]

1

This section specifies requirements that implementations shall meet to prevent data races (1.859). Every standard library function shall meet each requirement unless otherwise specified. Implementations may prevent data races in cases other than those specified below.

1

A C++ standard library function shall not directly or indirectly access objects (1.859) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function's arguments, including `this`.

1

A C++ standard library function shall not directly or indirectly modify objects (1.859) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function's non-const arguments, including `this`.

1

[*Note:* This means, for example, that implementations can't use a static object for internal purposes without synchronization because it could cause a data race even in programs that do not explicitly share objects between threads. — *end note*]

1

A C++ standard library function shall not access objects indirectly accessible via its arguments or via elements of its container arguments except by invoking functions required by its specification on those container elements.

1

Operations on iterators obtained by calling a standard library container or string member function may access the underlying container, but shall not modify it. [*Note:* In particular, container operations that invalidate iterators conflict with operations on iterators associated with that container. — *end note*]

1

Implementations may share their own internal objects between threads if the objects are not visible to users and are protected against data races.

1

Unless otherwise specified, C++ standard library functions shall perform all operations solely within the current thread if those operations have effects that are visible (1.859) to users.

1

[*Note:* This allows implementations to parallelize operations if there are no visible side effects. — *end note*]

17.674.0.1 Protection within classes [protection.within.classes]

1 It is unspecified whether any function signature or class described in Clauses 18 through 30 and Annex D is a `friend` of another class in the C++ standard library.

17.674.0.2 Derived classes [derivation]

1

An implementation may derive any class in the C++ standard library from a class with a name reserved to the implementation.

1 Certain classes defined in the C++ standard library are required to be derived from other classes in the C++ standard library. An implementation may derive such a class directly from the required base or indirectly

through a hierarchy of base classes with names reserved to the implementation.

2 In any case:

(2.1) — Every base class described as `virtual` shall be virtual;

(2.2) — Every base class described as non-`virtual` shall not be virtual;

(2.3) — Unless explicitly stated otherwise, types with distinct names shall be distinct types.[189]

17.677.0.1 Restrictions on exception handling [res.on.exception.handling]

1

Any of the functions defined in the C++ standard library can report a failure by throwing an exception of a type described in its **Throws:** paragraph. An implementation may strengthen the *exception-specification* for a non-virtual function by adding a non-throwing *noexcept-specification*.

1

A function may throw an object of a type not listed in its **Throws** clause if its type is derived from a type named in the **Throws** clause and would be caught by an exception handler for the base type.

1 Functions from the C standard library shall not throw exceptions[190] except when such a function calls a program-supplied function that throws an exception.[191]

2

Destructor operations defined in the C++ standard library shall not throw exceptions. Every destructor in the C++ standard library shall behave as if it had a non-throwing exception specification. Any other functions defined in the C++ standard library that do not have an *exception-specification* may throw implementation-defined exceptions unless otherwise specified.[192] An implementation may strengthen this implicit *exception-specification* by adding an explicit one.[193]

17.685.0.1 Restrictions on storage of pointers [res.on.pointer.storage]

1 Objects constructed by the standard library that may hold a user-supplied pointer value or an integer of type `std::intptr_t` shall store such values in a traceable pointer location (3.2532.0.1). [*Note:* Other libraries are strongly encouraged to do the same, since not doing so may result in accidental use of pointers that are not safely derived. Libraries that store pointers outside the user's address space should make it appear that they are stored and retrieved from a traceable pointer location. — *end note*]

17.685.0.2 Value of error codes [value.error.codes]

1

Certain functions in the C++ standard library report errors via a `std::error_code` (19.22.1.1) object. That object's `category()` member shall return `std::system_category()` for errors originating from the operating system, or a reference to an implementation-defined `error_category` object for errors originating elsewhere. The implementation shall define the possible values of `value()` for each of these error categories.

189) There is an implicit exception to this rule for types that are described as synonyms for basic integral types, such as `size_t` (18.2) and `streamoff` (27.56.2).

190) That is, the C library functions can all be treated as if they are marked `noexcept`. This allows implementations to make performance optimizations based on the absence of exceptions at runtime.

191) The functions `qsort()` and `bsearch()` (25.205) meet this condition.

192) In particular, they can report a failure to allocate storage by throwing an exception of type `bad_alloc`, or a class derived from `bad_alloc` (18.223.1.1). Library implementations should report errors by throwing exceptions of or derived from the standard exception classes (18.223.1.1, 18.241, 19.3).

193) That is, an implementation may provide an explicit *exception-specification* that defines the subset of "any" exceptions thrown by that function. This implies that the implementation may list implementation-defined types in such an *exception-specification*.

[*Example:* For operating systems that are based on POSIX, implementations are encouraged to define the `std::system_category()` values as identical to the POSIX `errno` values, with additional values as defined by the operating system's documentation. Implementations for operating systems that are not based on POSIX are encouraged to define values identical to the operating system's values. For errors that do not originate from the operating system, the implementation may provide enums for the associated values. — *end example*]

17.688.0.1 Moved-from state of library types [lib.types.movedfrom]

1

Objects of types defined in the C++ standard library may be moved from (12.1577). Move operations may be explicitly specified or implicitly generated. Unless otherwise specified, such moved-from objects shall be placed in a valid but unspecified state.

18 Language support library [language.support]

18.1 General [support.general]

1 This Clause describes the function signatures that are called implicitly, and the types of objects generated implicitly, during the execution of some C++ programs. It also describes the headers that declare these function signatures and define any related types.

2 The following subclauses describe common type definitions used throughout the library, characteristics of the predefined types, functions supporting start and termination of a C++ program, support for dynamic memory management, support for dynamic type identification, support for exception processing, support for initializer lists, and other runtime support, as summarized in Table 29.

Table 29 — Language support library summary

Subclause		Header(s)
18.2	Types	`<cstddef>`

18.41	Implementation properties	`<limits>`
		`<climits>`
		`<cfloat>`

18.114	Integer types	`<cstdint>`
18.127	Start and termination	`<cstdlib>`
18.159	Dynamic memory management	`<new>`
18.227	Type identification	`<typeinfo>`
18.241	Exception handling	`<exception>`
18.274	Initializer lists	`<initializer_list>`

18.295	Other runtime support	`<csignal>`
		`<csetjmp>`
		`<cstdalign>`
		`<cstdarg>`
		`<cstdbool>`
		`<cstdlib>`
		`<ctime>`

18.2 Types [support.types]

1 Table 30 describes the header `<cstddef>`.

Table 30 — Header `<cstddef>` synopsis

Type	Name(s)	
Macros:	`NULL`	`offsetof`
Types:	`ptrdiff_t`	`size_t`
	`max_align_t`	`nullptr_t`

2

The contents are the same as the Standard C library header `<stddef.h>`, with the following changes:

1

The macro `NULL` is an implementation-defined C++ null pointer constant in this International Standard (4.579).[194]

1

The macro `offsetof`(*type*, *member-designator*) accepts a restricted set of *type* arguments in this International Standard. If *type* is not a standard-layout class (Clause 9), the results are undefined.[195] The expression `offsetof`(*type*, *member-designator*) is never type-dependent (14.1390.0.1) and it is value-dependent (14.1430.0.1) if and only if *type* is dependent. The result of applying the `offsetof` macro to a field that is a static data member or a function member is undefined. No operation invoked by the `offsetof` macro shall throw an exception and `noexcept(offsetof(type, member-designator))` shall be `true`.

1 The type `ptrdiff_t` is an implementation-defined signed integer type that can hold the difference of two subscripts in an array object, as described in 5.2882.

2

The type `size_t` is an implementation-defined unsigned integer type that is large enough to contain the size in bytes of any object.

1

[*Note:* It is recommended that implementations choose types for `ptrdiff_t` and `size_t` whose integer conversion ranks (4.807) are no greater than that of `signed long int` unless a larger size is necessary to contain all the possible values. — *end note*]

1

The type `max_align_t` is a POD type whose alignment requirement is at least as great as that of every scalar type, and whose alignment requirement is supported in every context.

1

`nullptr_t` is defined as follows:

```
namespace std {
  typedef decltype(nullptr) nullptr_t;
}
```

The type for which `nullptr_t` is a synonym has the characteristics described in 3.3151.1 and 4.579. [*Note:* Although `nullptr`'s address cannot be taken, the address of another `nullptr_t` object that is an lvalue can be taken. — *end note*]

See also: Alignment (3.3924), Sizeof (5.2075.1), Additive operators (5.2882), Free store (12.988), and ISO C 7.1.6.

18.41 Implementation properties [support.limits]

18.41.1 In general [support.limits.general]

1 The headers `<limits>` (18.41.2), `<climits>`, and `<cfloat>` (18.110.1) supply characteristics of implementation-dependent arithmetic types (3.3151.1).

18.41.2 Numeric limits [limits]

18.41.2.1 Class template `numeric_limits` [limits.numeric]

1

194) Possible definitions include `0` and `0L`, but not `(void*)0`.

195) Note that `offsetof` is required to work as specified even if unary `operator&` is overloaded for any of the types involved.

The `numeric_limits` class template provides a C++ program with information about various properties of the implementation's representation of the arithmetic types.

1

Specializations shall be provided for each arithmetic type, both floating point and integer, including `bool`. The member `is_specialized` shall be `true` for all such specializations of `numeric_limits`.

1

For all members declared `static constexpr` in the `numeric_limits` template, specializations shall define these values in such a way that they are usable as constant expressions.

1

Non-arithmetic standard types, such as `complex<T>` (26.33.2), shall not have specializations.

18.53.0.1 Header `<limits>` synopsis [limits.syn]

```
namespace std {
  template<class T> class numeric_limits;
  enum float_round_style;
  enum float_denorm_style;

  template<> class numeric_limits<bool>;

  template<> class numeric_limits<char>;
  template<> class numeric_limits<signed char>;
  template<> class numeric_limits<unsigned char>;
  template<> class numeric_limits<char16_t>;
  template<> class numeric_limits<char32_t>;
  template<> class numeric_limits<wchar_t>;

  template<> class numeric_limits<short>;
  template<> class numeric_limits<int>;
  template<> class numeric_limits<long>;
  template<> class numeric_limits<long long>;
  template<> class numeric_limits<unsigned short>;
  template<> class numeric_limits<unsigned int>;
  template<> class numeric_limits<unsigned long>;
  template<> class numeric_limits<unsigned long long>;

  template<> class numeric_limits<float>;
  template<> class numeric_limits<double>;
  template<> class numeric_limits<long double>;
}
```

18.53.0.2 Class template `numeric_limits` [numeric.limits]

```
namespace std {
  template<class T> class numeric_limits {
  public:
    static constexpr bool is_specialized = false;
    static constexpr T min() noexcept { return T(); }
    static constexpr T max() noexcept { return T(); }
    static constexpr T lowest() noexcept { return T(); }

    static constexpr int  digits = 0;
    static constexpr int  digits10 = 0;
```

```
    static constexpr int  max_digits10 = 0;
    static constexpr bool is_signed = false;
    static constexpr bool is_integer = false;
    static constexpr bool is_exact = false;
    static constexpr int  radix = 0;
    static constexpr T epsilon() noexcept { return T(); }
    static constexpr T round_error() noexcept { return T(); }

    static constexpr int  min_exponent = 0;
    static constexpr int  min_exponent10 = 0;
    static constexpr int  max_exponent = 0;
    static constexpr int  max_exponent10 = 0;

    static constexpr bool has_infinity = false;
    static constexpr bool has_quiet_NaN = false;
    static constexpr bool has_signaling_NaN = false;
    static constexpr float_denorm_style has_denorm = denorm_absent;
    static constexpr bool has_denorm_loss = false;
    static constexpr T infinity() noexcept { return T(); }
    static constexpr T quiet_NaN() noexcept { return T(); }
    static constexpr T signaling_NaN() noexcept { return T(); }
    static constexpr T denorm_min() noexcept { return T(); }

    static constexpr bool is_iec559 = false;
    static constexpr bool is_bounded = false;
    static constexpr bool is_modulo = false;

    static constexpr bool traps = false;
    static constexpr bool tinyness_before = false;
    static constexpr float_round_style round_style = round_toward_zero;
  };

  template<class T> class numeric_limits<const T>;
  template<class T> class numeric_limits<volatile T>;
  template<class T> class numeric_limits<const volatile T>;
}
```

1

The default `numeric_limits<T>` template shall have all members, but with 0 or `false` values.

1

The value of each member of a specialization of `numeric_limits` on a *cv*-qualified type `cv T` shall be equal to the value of the corresponding member of the specialization on the unqualified type `T`.

18.57.0.1 `numeric_limits` members [numeric.limits.members]

`static constexpr T min() noexcept;`

1 Minimum finite value.[196]

2

For floating types with denormalization, returns the minimum positive normalized value.

1

196) Equivalent to `CHAR_MIN`, `SHRT_MIN`, `FLT_MIN`, `DBL_MIN`, etc.

Meaningful for all specializations in which `is_bounded != false`, or `is_bounded == false && is_signed == false`.

`static constexpr T max() noexcept;`

1 Maximum finite value.[197]

2

Meaningful for all specializations in which `is_bounded != false`.

`static constexpr T lowest() noexcept;`

1

A finite value `x` such that there is no other finite value `y` where `y < x`.[198]

1

Meaningful for all specializations in which `is_bounded != false`.

`static constexpr int digits;`

1

Number of `radix` digits that can be represented without change.

1

For integer types, the number of non-sign bits in the representation.

1 For floating point types, the number of `radix` digits in the mantissa.[199]

`static constexpr int digits10;`

1 Number of base 10 digits that can be represented without change.[200]

2 Meaningful for all specializations in which `is_bounded != false`.

`static constexpr int max_digits10;`

3 Number of base 10 digits required to ensure that values which differ are always differentiated.

4

Meaningful for all floating point types.

`static constexpr bool is_signed;`

1 True if the type is signed.

2 Meaningful for all specializations.

`static constexpr bool is_integer;`

3 True if the type is integer.

4

Meaningful for all specializations.

`static constexpr bool is_exact;`

197) Equivalent to `CHAR_MAX`, `SHRT_MAX`, `FLT_MAX`, `DBL_MAX`, etc.

198) `lowest()` is necessary because not all floating-point representations have a smallest (most negative) value that is the negative of the largest (most positive) finite value.

199) Equivalent to `FLT_MANT_DIG`, `DBL_MANT_DIG`, `LDBL_MANT_DIG`.

200) Equivalent to `FLT_DIG`, `DBL_DIG`, `LDBL_DIG`.

1

True if the type uses an exact representation. All integer types are exact, but not all exact types are integer. For example, rational and fixed-exponent representations are exact but not integer.

1 Meaningful for all specializations.

```
static constexpr int radix;
```

2 For floating types, specifies the base or radix of the exponent representation (often 2).[201]

3 For integer types, specifies the base of the representation.[202]

4 Meaningful for all specializations.

```
static constexpr T epsilon() noexcept;
```

5 Machine epsilon: the difference between 1 and the least value greater than 1 that is representable.[203]

6 Meaningful for all floating point types.

```
static constexpr T round_error() noexcept;
```

7 Measure of the maximum rounding error.[204]

```
static constexpr int  min_exponent;
```

8 Minimum negative integer such that `radix` raised to the power of one less than that integer is a normalized floating point number.[205]

9 Meaningful for all floating point types.

```
static constexpr int  min_exponent10;
```

10 Minimum negative integer such that 10 raised to that power is in the range of normalized floating point numbers.[206]

11 Meaningful for all floating point types.

```
static constexpr int  max_exponent;
```

12 Maximum positive integer such that `radix` raised to the power one less than that integer is a representable finite floating point number.[207]

13 Meaningful for all floating point types.

```
static constexpr int  max_exponent10;
```

14 Maximum positive integer such that 10 raised to that power is in the range of representable finite floating point numbers.[208]

15 Meaningful for all floating point types.

```
static constexpr bool has_infinity;
```

201) Equivalent to `FLT_RADIX`.
202) Distinguishes types with bases other than 2 (e.g. BCD).
203) Equivalent to `FLT_EPSILON`, `DBL_EPSILON`, `LDBL_EPSILON`.
204) Rounding error is described in ISO/IEC 10967-1 Language independent arithmetic - Part 1 Section 5.2.8 and Annex A Rationale Section A.5.2.8 - Rounding constants.
205) Equivalent to `FLT_MIN_EXP`, `DBL_MIN_EXP`, `LDBL_MIN_EXP`.
206) Equivalent to `FLT_MIN_10_EXP`, `DBL_MIN_10_EXP`, `LDBL_MIN_10_EXP`.
207) Equivalent to `FLT_MAX_EXP`, `DBL_MAX_EXP`, `LDBL_MAX_EXP`.
208) Equivalent to `FLT_MAX_10_EXP`, `DBL_MAX_10_EXP`, `LDBL_MAX_10_EXP`.

16 True if the type has a representation for positive infinity.

17 Meaningful for all floating point types.

18

Shall be `true` for all specializations in which `is_iec559 != false`.

```
static constexpr bool has_quiet_NaN;
```

1

True if the type has a representation for a quiet (non-signaling) "Not a Number."[209]

1 Meaningful for all floating point types.

2 Shall be `true` for all specializations in which `is_iec559 != false`.

```
static constexpr bool has_signaling_NaN;
```

3 True if the type has a representation for a signaling "Not a Number."[210]

4 Meaningful for all floating point types.

5 Shall be `true` for all specializations in which `is_iec559 != false`.

```
static constexpr float_denorm_style has_denorm;
```

6 `denorm_present` if the type allows denormalized values (variable number of exponent bits)[211], `denorm_absent` if the type does not allow denormalized values, and `denorm_indeterminate` if it is indeterminate at compile time whether the type allows denormalized values.

7 Meaningful for all floating point types.

```
static constexpr bool has_denorm_loss;
```

8

True if loss of accuracy is detected as a denormalization loss, rather than as an inexact result.[212]

```
static constexpr T infinity() noexcept;
```

1

Representation of positive infinity, if available.[213]

1

Meaningful for all specializations for which `has_infinity != false`. Required in specializations for which `is_iec559 != false`.

```
static constexpr T quiet_NaN() noexcept;
```

1 Representation of a quiet "Not a Number," if available.[214]

2 Meaningful for all specializations for which `has_quiet_NaN != false`. Required in specializations for which `is_iec559 != false`.

```
static constexpr T signaling_NaN() noexcept;
```

209) Required by LIA-1.
210) Required by LIA-1.
211) Required by LIA-1.
212) See IEC 559.
213) Required by LIA-1.
214) Required by LIA-1.

3 Representation of a signaling "Not a Number," if available.[215]

4 Meaningful for all specializations for which `has_signaling_NaN != false`. Required in specializations for which `is_iec559 != false`.

`static constexpr T denorm_min() noexcept;`

5 Minimum positive denormalized value.[216]

6 Meaningful for all floating point types.

7

In specializations for which `has_denorm == false`, returns the minimum positive normalized value.

`static constexpr bool is_iec559;`

1

True if and only if the type adheres to IEC 559 standard.[217]

1 Meaningful for all floating point types.

`static constexpr bool is_bounded;`

2 True if the set of values representable by the type is finite.[218] [*Note:* All fundamental types (3.3151.1) are bounded. This member would be false for arbitrary precision types. — *end note*]

3 Meaningful for all specializations.

`static constexpr bool is_modulo;`

4

True if the type is modulo.[219] A type is modulo if, for any operation involving `+`, `-`, or `*` on values of that type whose result would fall outside the range `[min(),max()]`, the value returned differs from the true value by an integer multiple of `max() - min() + 1`.

1

On most machines, this is `false` for floating types, `true` for unsigned integers, and `true` for signed integers.

1 Meaningful for all specializations.

`static constexpr bool traps;`

2 `true` if, at program startup, there exists a value of the type that would cause an arithmetic operation using that value to trap.[220]

3 Meaningful for all specializations.

`static constexpr bool tinyness_before;`

4 `true` if tinyness is detected before rounding.[221]

5 Meaningful for all floating point types.

215) Required by LIA-1.
216) Required by LIA-1.
217) International Electrotechnical Commission standard 559 is the same as IEEE 754.
218) Required by LIA-1.
219) Required by LIA-1.
220) Required by LIA-1.
221) Refer to IEC 559. Required by LIA-1.

```
static constexpr float_round_style round_style;
```

6 The rounding style for the type.[222]

7 Meaningful for all floating point types. Specializations for integer types shall return `round_toward_zero`.

18.107.0.1 Type `float_round_style` [round.style]

```
namespace std {
  enum float_round_style {
    round_indeterminate       = -1,
    round_toward_zero         =  0,
    round_to_nearest          =  1,
    round_toward_infinity     =  2,
    round_toward_neg_infinity =  3
  };
}
```

1 The rounding mode for floating point arithmetic is characterized by the values:

(1.1) — `round_indeterminate` if the rounding style is indeterminable

(1.2) — `round_toward_zero` if the rounding style is toward zero

(1.3) — `round_to_nearest` if the rounding style is to the nearest representable value

(1.4) — `round_toward_infinity` if the rounding style is toward infinity

(1.5) — `round_toward_neg_infinity` if the rounding style is toward negative infinity

18.107.0.2 Type `float_denorm_style` [denorm.style]

```
namespace std {
  enum float_denorm_style {
    denorm_indeterminate = -1,
    denorm_absent = 0,
    denorm_present = 1
  };
}
```

1 The presence or absence of denormalization (variable number of exponent bits) is characterized by the values:

(1.1) — `denorm_indeterminate` if it cannot be determined whether or not the type allows denormalized values

(1.2) — `denorm_absent` if the type does not allow denormalized values

(1.3) — `denorm_present` if the type does allow denormalized values

18.107.0.3 `numeric_limits` specializations [numeric.special]

1

All members shall be provided for all specializations. However, many values are only required to be meaningful under certain conditions (for example, `epsilon()` is only meaningful if `is_integer` is `false`). Any value that is not "meaningful" shall be set to 0 or `false`.

1 [*Example:*

222) Equivalent to `FLT_ROUNDS`. Required by LIA-1.

```
namespace std {
  template<> class numeric_limits<float> {
  public:
    static constexpr bool is_specialized = true;

    inline static constexpr float min() noexcept { return 1.17549435E-38F; }
    inline static constexpr float max() noexcept { return 3.40282347E+38F; }
    inline static constexpr float lowest() noexcept { return -3.40282347E+38F; }

    static constexpr int digits   = 24;
    static constexpr int digits10 =  6;
    static constexpr int max_digits10 =  9;

    static constexpr bool is_signed  = true;
    static constexpr bool is_integer = false;
    static constexpr bool is_exact   = false;

    static constexpr int radix = 2;
    inline static constexpr float epsilon() noexcept     { return 1.19209290E-07F; }
    inline static constexpr float round_error() noexcept { return 0.5F; }

    static constexpr int min_exponent   = -125;
    static constexpr int min_exponent10 = - 37;
    static constexpr int max_exponent   = +128;
    static constexpr int max_exponent10 = + 38;

    static constexpr bool has_infinity             = true;
    static constexpr bool has_quiet_NaN            = true;
    static constexpr bool has_signaling_NaN        = true;
    static constexpr float_denorm_style has_denorm = denorm_absent;
    static constexpr bool has_denorm_loss          = false;

    inline static constexpr float infinity()      noexcept { return value; }
    inline static constexpr float quiet_NaN()     noexcept { return value; }
    inline static constexpr float signaling_NaN() noexcept { return value; }
    inline static constexpr float denorm_min()    noexcept { return min(); }

    static constexpr bool is_iec559  = true;
    static constexpr bool is_bounded = true;
    static constexpr bool is_modulo  = false;
    static constexpr bool traps      = true;
    static constexpr bool tinyness_before = true;

    static constexpr float_round_style round_style = round_to_nearest;
  };
}
```

— *end example*]

2 The specialization for `bool` shall be provided as follows:

```
namespace std {
   template<> class numeric_limits<bool> {
   public:
     static constexpr bool is_specialized = true;
     static constexpr bool min() noexcept { return false; }
```

```
    static constexpr bool max() noexcept { return true; }
    static constexpr bool lowest() noexcept { return false; }

    static constexpr int  digits = 1;
    static constexpr int  digits10 = 0;
    static constexpr int  max_digits10 = 0;

    static constexpr bool is_signed = false;
    static constexpr bool is_integer = true;
    static constexpr bool is_exact = true;
    static constexpr int  radix = 2;
    static constexpr bool epsilon() noexcept { return 0; }
    static constexpr bool round_error() noexcept { return 0; }

    static constexpr int  min_exponent = 0;
    static constexpr int  min_exponent10 = 0;
    static constexpr int  max_exponent = 0;
    static constexpr int  max_exponent10 = 0;

    static constexpr bool has_infinity = false;
    static constexpr bool has_quiet_NaN = false;
    static constexpr bool has_signaling_NaN = false;
    static constexpr float_denorm_style has_denorm = denorm_absent;
    static constexpr bool has_denorm_loss = false;
    static constexpr bool infinity() noexcept { return 0; }
    static constexpr bool quiet_NaN() noexcept { return 0; }
    static constexpr bool signaling_NaN() noexcept { return 0; }
    static constexpr bool denorm_min() noexcept { return 0; }

    static constexpr bool is_iec559 = false;
    static constexpr bool is_bounded = true;
    static constexpr bool is_modulo = false;

    static constexpr bool traps = false;
    static constexpr bool tinyness_before = false;
    static constexpr float_round_style round_style = round_toward_zero;
  };
}
```

18.110.1 C library [c.limits]

1 Table 31 describes the header `<climits>`.

Table 31 — Header `<climits>` synopsis

Type	Name(s)				
Values:					
CHAR_BIT	INT_MAX	LONG_MAX	SCHAR_MIN	SHRT_MIN	ULLONG_MAX
CHAR_MAX	LLONG_MAX	LONG_MIN	SCHAR_MAX	UCHAR_MAX	ULONG_MAX
CHAR_MIN	LLONG_MIN	MB_LEN_MAX	SHRT_MAX	UINT_MAX	USHRT_MAX
INT_MIN					

2

The contents are the same as the Standard C library header `<limits.h>`. [*Note:* The types of the constants defined by macros in `<climits>` are not required to match the types to which the macros refer. — *end note*]

1 Table 32 describes the header `<cfloat>`.

Table 32 — Header `<cfloat>` synopsis

Type	Name(s)		
Values:			
DBL_DIG	DBL_MIN_EXP	FLT_MAX_EXP	LDBL_MANT_DIG
DBL_EPSILON	DECIMAL_DIG	FLT_MIN	LDBL_MAX_10_EXP
DBL_MANT_DIG	FLT_DIG	FLT_MIN_10_EXP	LDBL_MAX_EXP
DBL_MAX	FLT_EPSILON	FLT_MIN_EXP	LDBL_MAX
DBL_MAX_10_EXP	FLT_EVAL_METHOD	FLT_RADIX	LDBL_MIN
DBL_MAX_EXP	FLT_MANT_DIG	FLT_ROUNDS	LDBL_MIN_10_EXP
DBL_MIN	FLT_MAX	LDBL_DIG	LDBL_MIN_EXP
DBL_MIN_10_EXP	FLT_MAX_10_EXP	LDBL_EPSILON	

2

The contents are the same as the Standard C library header `<float.h>`.

See also: ISO C 7.1.5, 5.2.4.2.2, 5.2.4.2.1.

18.114 Integer types [cstdint]

18.114.1 Header `<cstdint>` synopsis [cstdint.syn]

```
namespace std {
  typedef signed integer type int8_t;   // optional
  typedef signed integer type int16_t;  // optional
  typedef signed integer type int32_t;  // optional
  typedef signed integer type int64_t;  // optional

  typedef signed integer type int_fast8_t;
  typedef signed integer type int_fast16_t;
  typedef signed integer type int_fast32_t;
  typedef signed integer type int_fast64_t;

  typedef signed integer type int_least8_t;
  typedef signed integer type int_least16_t;
  typedef signed integer type int_least32_t;
  typedef signed integer type int_least64_t;

  typedef signed integer type intmax_t;
  typedef signed integer type intptr_t;         // optional

  typedef unsigned integer type uint8_t;        // optional
  typedef unsigned integer type uint16_t;       // optional
  typedef unsigned integer type uint32_t;       // optional
  typedef unsigned integer type uint64_t;       // optional

  typedef unsigned integer type uint_fast8_t;
  typedef unsigned integer type uint_fast16_t;
  typedef unsigned integer type uint_fast32_t;
  typedef unsigned integer type uint_fast64_t;
```

```
  typedef unsigned integer type uint_least8_t;
  typedef unsigned integer type uint_least16_t;
  typedef unsigned integer type uint_least32_t;
  typedef unsigned integer type uint_least64_t;

  typedef unsigned integer type uintmax_t;
  typedef unsigned integer type uintptr_t;      // optional
} // namespace std
```

1

The header also defines numerous macros of the form:

```
INT_[FAST LEAST]{8 16 32 64}_MIN
[U]INT_[FAST LEAST]{8 16 32 64}_MAX
INT{MAX PTR}_MIN
[U]INT{MAX PTR}_MAX
{PTRDIFF SIG_ATOMIC WCHAR WINT}{_MAX _MIN}
SIZE_MAX
```

plus function macros of the form:

```
[U]INT{8 16 32 64 MAX}_C
```

1

The header defines all functions, types, and macros the same as 7.18 in the C standard. [*Note:* The macros defined by `<cstdint>` are provided unconditionally. In particular, the symbols `__STDC_LIMIT_MACROS` and `__STDC_CONSTANT_MACROS` (mentioned in footnotes 219, 220, and 222 in the C standard) play no role in C++. — *end note*]

18.127 Start and termination [support.start.term]

1 Table 33 describes some of the contents of the header `<cstdlib>`.

Table 33 — Header `<cstdlib>` synopsis

Type	Name(s)		
Macros:	`EXIT_FAILURE`	`EXIT_SUCCESS`	
Functions:	`_Exit`	`abort`	`atexit`
	`at_quick_exit`	`exit`	`quick_exit`

2 The contents are the same as the Standard C library header `<stdlib.h>`, with the following changes:

```
[[noreturn]] void _Exit(int status) noexcept;
```

3

The function `_Exit(int status)` has additional behavior in this International Standard:

— The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to `atexit()` (3.2200.1).

```
[[noreturn]] void abort(void) noexcept;
```

1

The function `abort()` has additional behavior in this International Standard:

— The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to `atexit()` (3.2200.1).

```
extern "C" int atexit(void (*f)(void)) noexcept;
extern "C++" int atexit(void (*f)(void)) noexcept;
```

1 *Effects:* The `atexit()` functions register the function pointed to by `f` to be called without arguments at normal program termination. It is unspecified whether a call to `atexit()` that does not happen before (1.859) a call to `exit()` will succeed. [*Note:* The `atexit()` functions do not introduce a data race (17.607.0.1). — *end note*]

1 *Implementation limits:* The implementation shall support the registration of at least 32 functions.

1 *Returns:* The `atexit()` function returns zero if the registration succeeds, non-zero if it fails.

```
[[noreturn]] void exit(int status)
```

2 The function `exit()` has additional behavior in this International Standard:

— First, objects with thread storage duration and associated with the current thread are destroyed. Next, objects with static storage duration are destroyed and functions registered by calling `atexit` are called.[223] See 3.2200.1 for the order of destructions and calls. (Automatic objects are not destroyed as a result of calling `exit()`.)[224]

If control leaves a registered function called by `exit` because the function does not provide a handler for a thrown exception, `std::terminate()` shall be called (15.308.1).

— Next, all open C streams (as mediated by the function signatures declared in `<cstdio>`) with unwritten buffered data are flushed, all open C streams are closed, and all files created by calling `tmpfile()` are removed.

— Finally, control is returned to the host environment. If `status` is zero or `EXIT_SUCCESS`, an implementation-defined form of the status *successful termination* is returned. If `status` is `EXIT_FAILURE`, an implementation-defined form of the status *unsuccessful termination* is returned. Otherwise the status returned is implementation-defined.[225]

```
extern "C" int at_quick_exit(void (*f)(void)) noexcept;
extern "C++" int at_quick_exit(void (*f)(void)) noexcept;
```

1 *Effects:* The `at_quick_exit()` functions register the function pointed to by `f` to be called without arguments when `quick_exit` is called. It is unspecified whether a call to `at_quick_exit()` that does not happen before (1.859) all calls to `quick_exit` will succeed. [*Note:* The `at_quick_exit()` functions do not introduce a data race (17.607.0.1). — *end note*] [*Note:* The order of registration may be indeterminate if `at_quick_exit` was called from more than one thread. — *end note*] [*Note:* The `at_quick_exit` registrations are distinct from the `atexit` registrations, and applications may need to call both registration functions with the same argument. — *end note*]

2 *Implementation limits:* The implementation shall support the registration of at least 32 functions.

3 *Returns:* Zero if the registration succeeds, non-zero if it fails.

```
[[noreturn]] void quick_exit(int status) noexcept;
```

223) A function is called for every time it is registered.

224) Objects with automatic storage duration are all destroyed in a program whose function `main()` contains no automatic objects and executes the call to `exit()`. Control can be transferred directly to such a `main()` by throwing an exception that is caught in `main()`.

225) The macros `EXIT_FAILURE` and `EXIT_SUCCESS` are defined in `<cstdlib>`.

4

Effects: Functions registered by calls to `at_quick_exit` are called in the reverse order of their registration, except that a function shall be called after any previously registered functions that had already been called at the time it was registered. Objects shall not be destroyed as a result of calling `quick_exit`. If control leaves a registered function called by `quick_exit` because the function does not provide a handler for a thrown exception, `std::terminate()` shall be called. [*Note:* `at_quick_exit` may call a registered function from a different thread than the one that registered it, so registered functions should not rely on the identity of objects with thread storage duration. — *end note*] After calling registered functions, `quick_exit` shall call `_Exit(status)`. [*Note:* The standard file buffers are not flushed. SEE: ISO C 7.20.4.4. — *end note*]

18.159 Dynamic memory management [support.dynamic]

1 The header `<new>` defines several functions that manage the allocation of dynamic storage in a program. It also defines components for reporting storage management errors.

Header `<new>` synopsis

```
namespace std {
  class bad_alloc;
  class bad_array_new_length;
  struct nothrow_t {};
  extern const nothrow_t nothrow;
  typedef void (*new_handler)();
  new_handler get_new_handler() noexcept;
  new_handler set_new_handler(new_handler new_p) noexcept;
}

void* operator new(std::size_t size);
void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
void  operator delete(void* ptr) noexcept;
void  operator delete(void* ptr, const std::nothrow_t&) noexcept;
void  operator delete(void* ptr, std::size_t size) noexcept;
void  operator delete(void* ptr, std::size_t size,
                      const std::nothrow_t&) noexcept;
void* operator new[](std::size_t size);
void* operator new[](std::size_t size, const std::nothrow_t&) noexcept;
void  operator delete[](void* ptr) noexcept;
void  operator delete[](void* ptr, const std::nothrow_t&) noexcept;
void  operator delete[](void* ptr, std::size_t size) noexcept;
void  operator delete[](void* ptr, std::size_t size,
                        const std::nothrow_t&) noexcept;

void* operator new  (std::size_t size, void* ptr) noexcept;
void* operator new[](std::size_t size, void* ptr) noexcept;
void  operator delete  (void* ptr, void*) noexcept;
void  operator delete[](void* ptr, void*) noexcept;
```

18.159.1 Storage allocation and deallocation [new.delete]

1 Except where otherwise specified, the provisions of (3.2331.1) apply to the library versions of `operator new` and `operator delete`.

18.159.1.1 Single-object forms [new.delete.single]

```
void* operator new(std::size_t size);
```

1 *Effects:* The *allocation function* (3.2361.0.1) called by a *new-expression* (5.2221.1) to allocate `size` bytes of storage suitably aligned to represent any object of that size.

1 *Replaceable:* a C++ program may define a function with this function signature that displaces the default version defined by the C++ standard library.

1 *Required behavior:* Return a non-null pointer to suitably aligned storage (3.2331.1), or else throw a `bad_alloc` exception. This requirement is binding on a replacement version of this function.

1 *Default behavior:*

— Executes a loop: Within the loop, the function first attempts to allocate the requested storage. Whether the attempt involves a call to the Standard C library function `malloc` is unspecified.

— Returns a pointer to the allocated storage if the attempt is successful. Otherwise, if the current `new_handler` (18.226.0.3) is a null pointer value, throws `bad_alloc`.

— Otherwise, the function calls the current `new_handler` function (18.226.0.1). If the called function returns, the loop repeats.

— The loop terminates when an attempt to allocate the requested storage is successful or when a called `new_handler` function does not return.

```
void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
```

1 *Effects:* Same as above, except that it is called by a placement version of a *new-expression* when a C++ program prefers a null pointer result as an error indication, instead of a `bad_alloc` exception.

1 *Replaceable:* a C++ program may define a function with this function signature that displaces the default version defined by the C++ standard library.

2 *Required behavior:* Return a non-null pointer to suitably aligned storage (3.2331.1), or else return a null pointer. This nothrow version of `operator new` returns a pointer obtained as if acquired from the (possibly replaced) ordinary version. This requirement is binding on a replacement version of this function.

1 *Default behavior:* Calls `operator new(size)`. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

2 [*Example:*

```
T* p1 = new T;                  // throws bad_alloc if it fails
T* p2 = new(nothrow) T;         // returns nullptr if it fails
```

— *end example*]

```
void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
```

1 *Effects:* The *deallocation function* (3.2428.0.1) called by a *delete-expression* to render the value of `ptr` invalid.

2 *Replaceable:* a C++ program may define a function with signature `void operator delete(void* ptr) noexcept` that displaces the default version defined by the C++ standard library. If this function (without `size` parameter) is defined, the program should also define `void operator delete(void* ptr, std::size_t size) noexcept`. If this function with `size` parameter is defined, the program shall also define the version without the `size` parameter. [*Note:* The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. — *end note*]

1 *Requires:* *ptr* shall be a null pointer or its value shall be a value returned by an earlier call to the (possibly replaced) `operator new(std::size_t)` or `operator new(std::size_t,const std::nothrow_t&)` which has not been invalidated by an intervening call to `operator delete(void*)`.

1 *Requires:* If an implementation has strict pointer safety (3.2532.0.1) then `ptr` shall be a safely-derived pointer.

2 *Requires:* If present, the `std::size_t size` argument shall equal the size argument passed to the allocation function that returned `ptr`.

3 *Required behavior:* Calls to `operator delete(void* ptr, std::size_t size)` may be changed to calls to `operator delete(void* ptr)` without affecting memory allocation. [*Note:* A conforming implementation is for `operator delete(void* ptr, std::size_t size)` to simply call `operator delete(ptr)`. — *end note*]

4 *Default behavior:* the function `operator delete(void* ptr, std::size_t size)` calls `operator delete(ptr)`. [*Note:* See the note in the above *Replaceable* paragraph. — *end note*]

5 *Default behavior:* If `ptr` is null, does nothing. Otherwise, reclaims the storage allocated by the earlier call to `operator new`.

1 *Remarks:* It is unspecified under what conditions part or all of such reclaimed storage will be allocated by subsequent calls to `operator new` or any of `calloc`, `malloc`, or `realloc`, declared in `<cstdlib>`.

```
void operator delete(void* ptr, const std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::size_t size, const std::nothrow_t&) noexcept;
```

1 *Effects:* The *deallocation function* (3.2428.0.1) called by the implementation to render the value of `ptr` invalid when the constructor invoked from a nothrow placement version of the *new-expression* throws an exception.

2 *Replaceable:* a C++ program may define a function with signature `void operator delete(void* ptr, const std::nothrow_t&) noexcept` that displaces the default version defined by the C++ standard library. If this function (without `size` parameter) is defined, the program should also define `void operator delete(void* ptr, std::size_t size, const std::nothrow_t&) noexcept`. If this function with `size` parameter is defined, the program shall also define the version without the `size` parameter. [*Note:* The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. — *end note*]

3 *Requires:* If an implementation has strict pointer safety (3.2532.0.1) then `ptr` shall be a safely-derived pointer.

4 *Requires:* If present, the `std::size_t size` argument must equal the size argument passed to the allocation function that returned `ptr`.

5 *Required behavior:* Calls to `operator delete(void* ptr, std::size_t size, const std::nothrow_t&)` may be changed to calls to `operator delete(void* ptr, const std::nothrow_t&)` without affecting memory allocation. [*Note:* A conforming implementation is for `operator delete(void* ptr, std::size_t size, const std::nothrow_t&)` to simply call `operator delete(void* ptr, const std::nothrow_t&)`. — *end note*]

6 *Default behavior:* `operator delete(void* ptr, std::size_t size, const std::nothrow_t&)` calls `operator delete(ptr, std::nothrow)`, and `operator delete(void* ptr, const std::nothrow_t&)` calls `operator delete(ptr)`.

18.196.0.1 Array forms [new.delete.array]

```
void* operator new[](std::size_t size);
```

1 *Effects:* The *allocation function* (3.2361.0.1) called by the array form of a *new-expression* (5.2221.1) to allocate `size` bytes of storage suitably aligned to represent any array object of that size or smaller.[226]

1 *Replaceable:* a C++ program can define a function with this function signature that displaces the default version defined by the C++ standard library.

2 *Required behavior:* Same as for `operator new(std::size_t)`. This requirement is binding on a replacement version of this function.

1 *Default behavior:* Returns `operator new(size)`.

```
void* operator new[](std::size_t size, const std::nothrow_t&) noexcept;
```

1 *Effects:* Same as above, except that it is called by a placement version of a *new-expression* when a C++ program prefers a null pointer result as an error indication, instead of a `bad_alloc` exception.

2 *Replaceable:* a C++ program can define a function with this function signature that displaces the default version defined by the C++ standard library.

3 *Required behavior:* Return a non-null pointer to suitably aligned storage (3.2331.1), or return a null pointer. This requirement is binding on a replacement version of this function.

4 *Default behavior:* Calls `operator new[](size)`. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

```
void operator delete[](void* ptr) noexcept;
void operator delete[](void* ptr, std::size_t size) noexcept;
```

5 *Effects:* The *deallocation function* (3.2428.0.1) called by the array form of a *delete-expression* to render the value of `ptr` invalid.

1 *Replaceable:* a C++ program can define a function with signature `void operator delete[](void* ptr) noexcept` that displaces the default version defined by the C++ standard library. If this function

226) It is not the direct responsibility of `operator new[](std::size_t)` or `operator delete[](void*)` to note the repetition count or element size of the array. Those operations are performed elsewhere in the array `new` and `delete` expressions. The array `new` expression, may, however, increase the `size` argument to `operator new[](std::size_t)` to obtain space to store supplemental information.

(without `size` parameter) is defined, the program should also define `void operator delete[](void* ptr, std::size_t size) noexcept`. If this function with `size` parameter is defined, the program shall also define the version without the `size` parameter. [*Note:* The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. — *end note*]

2

Requires: *ptr* shall be a null pointer or its value shall be the value returned by an earlier call to `operator new[](std::size_t)` or `operator new[](std::size_t,const std::nothrow_t&)` which has not been invalidated by an intervening call to `operator delete[](void*)`.

1 *Requires:* If present, the `std::size_t size` argument must equal the size argument passed to the allocation function that returned `ptr`.

2 *Required behavior:* Calls to `operator delete[](void* ptr, std::size_t size)` may be changed to calls to `operator delete[](void* ptr)` without affecting memory allocation. [*Note:* A conforming implementation is for `operator delete[](void* ptr, std::size_t size)` to simply call `operator delete[](void* ptr)`. — *end note*]

3 *Requires:* If an implementation has strict pointer safety (3.2532.0.1) then `ptr` shall be a safely-derived pointer.

4

Default behavior: `operator delete[](void* ptr, std::size_t size)` calls `operator delete[](ptr)`, and `operator delete[](void* ptr)` calls `operator delete(ptr)`.

```
void operator delete[](void* ptr, const std::nothrow_t&) noexcept;
void operator delete[](void* ptr, std::size_t size, const std::nothrow_t&) noexcept;
```

1 *Effects:* The *deallocation function* (3.2428.0.1) called by the implementation to render the value of `ptr` invalid when the constructor invoked from a nothrow placement version of the array *new-expression* throws an exception.

2 *Replaceable:* a C++ program may define a function with signature `void operator delete[](void* ptr, const std::nothrow_t&) noexcept` that displaces the default version defined by the C++ standard library. If this function (without `size` parameter) is defined, the program should also define `void operator delete[](void* ptr, std::size_t size, const std::nothrow_t&) noexcept`. If this function with `size` parameter is defined, the program shall also define the version without the `size` parameter. [*Note:* The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. — *end note*]

3 *Requires:* If an implementation has strict pointer safety (3.2532.0.1) then `ptr` shall be a safely-derived pointer.

4 *Requires:* If present, the `std::size_t size` argument must equal the size argument passed to the allocation function that returned `ptr`.

5 *Required behavior:* Calls to `operator delete[](void* ptr, std::size_t size, const std::nothrow_t&)` may be changed to calls to `operator delete[](void* ptr, const std::nothrow_t&)` without affecting memory allocation. [*Note:* A conforming implementation is for `operator delete[](void* ptr, std::size_t size, const std::nothrow_t&)` to simply call `operator delete[](void* ptr, const std::nothrow_t&)`. — *end note*]

6 *Default behavior:* `operator delete[](void* ptr, std::size_t size, const std::nothrow_t&)` calls `operator delete[](ptr, std::nothrow)`, and `operator delete[](void* ptr, const std::nothrow_t&)` calls `operator delete[](ptr)`.

18.203.0.1 Placement forms [new.delete.placement]

1

These functions are reserved, a C++ program may not define functions that displace the versions in the Standard C++ library (17.194.1). The provisions of (3.2331.1) do not apply to these reserved placement forms of `operator new` and `operator delete`.

`void* operator new(std::size_t size, void* ptr) noexcept;`

1 *Returns:* `ptr`.

2

Remarks: Intentionally performs no other action.

1 [*Example:* This can be useful for constructing an object at a known address:

```
void* place = operator new(sizeof(Something));
Something* p = new (place) Something();
```

— *end example*]

`void* operator new[](std::size_t size, void* ptr) noexcept;`

2 *Returns:* `ptr`.

3 *Remarks:* Intentionally performs no other action.

`void operator delete(void* ptr, void*) noexcept;`

4 *Effects:* Intentionally performs no action.

5 *Requires:* If an implementation has strict pointer safety (3.2532.0.1) then `ptr` shall be a safely-derived pointer.

6 *Remarks:* Default function called when any part of the initialization in a placement new expression that invokes the library's non-array placement operator new terminates by throwing an exception (5.2221.1).

`void operator delete[](void* ptr, void*) noexcept;`

7 *Effects:* Intentionally performs no action.

8 *Requires:* If an implementation has strict pointer safety (3.2532.0.1) then `ptr` shall be a safely-derived pointer.

9 *Remarks:* Default function called when any part of the initialization in a placement new expression that invokes the library's array placement operator new terminates by throwing an exception (5.2221.1).

18.220.0.1 Data races [new.delete.dataraces]

1

For purposes of determining the existence of data races, the library versions of `operator new`, user replacement versions of global `operator new`, the C standard library functions `calloc` and `malloc`, the library versions of `operator delete`, user replacement versions of `operator delete`, the C standard library function `free`, and the C standard library function `realloc` shall not introduce a data race (17.607.0.1). Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before (1.859) the next allocation (if any) in this order.

18.223.1 Storage allocation errors [alloc.errors]

18.223.1.1 Class bad_alloc [bad.alloc]

```
namespace std {
  class bad_alloc : public exception {
  public:
    bad_alloc() noexcept;
    bad_alloc(const bad_alloc&) noexcept;
    bad_alloc& operator=(const bad_alloc&) noexcept;
    virtual const char* what() const noexcept;
  };
}
```

1 The class `bad_alloc` defines the type of objects thrown as exceptions by the implementation to report a failure to allocate storage.

`bad_alloc() noexcept;`

2 *Effects:* Constructs an object of class `bad_alloc`.

3 *Remarks:* The result of calling `what()` on the newly constructed object is implementation-defined.

```
bad_alloc(const bad_alloc&) noexcept;
bad_alloc& operator=(const bad_alloc&) noexcept;
```

1 *Effects:* Copies an object of class `bad_alloc`.

`virtual const char* what() const noexcept;`

1 *Returns:* An implementation-defined NTBS.

18.225.0.1 Class bad_array_new_length [new.badlength]

```
namespace std {
  class bad_array_new_length : public bad_alloc {
  public:
    bad_array_new_length() noexcept;
  };
}
```

1 The class `bad_array_new_length` defines the type of objects thrown as exceptions by the implementation to report an attempt to allocate an array of size less than zero or greater than an implementation-defined limit (5.2221.1).

`bad_array_new_length() noexcept;`

1 *Effects:* constructs an object of class `bad_array_new_length`.

2 *Remarks:* the result of calling `what()` on the newly constructed object is implementation-defined.

18.226.0.1 Type new_handler [new.handler]

```
typedef void (*new_handler)();
```

1 The type of a *handler function* to be called by `operator new()` or `operator new[]()` (18.159.1) when they cannot satisfy a request for additional storage.

2 *Required behavior:* A `new_handler` shall perform one of the following:

(2.1) — make more storage available for allocation and then return;

(2.2) — throw an exception of type `bad_alloc` or a class derived from `bad_alloc`;

(2.3) — terminate execution of the program without returning to the caller;

18.226.0.2 `set_new_handler` [set.new.handler]

```
new_handler set_new_handler(new_handler new_p) noexcept;
```

1 *Effects:* Establishes the function designated by `new_p` as the current `new_handler`.

2 *Returns:* The previous `new_handler`.

3 *Remarks:* The initial `new_handler` is a null pointer.

18.226.0.3 `get_new_handler` [get.new.handler]

```
new_handler get_new_handler() noexcept;
```

1 *Returns:* The current `new_handler`. [*Note:* This may be a null pointer value. — *end note*]

18.227 Type identification [support.rtti]

1 The header `<typeinfo>` defines a type associated with type information generated by the implementation. It also defines two types for reporting dynamic type identification errors.

Header `<typeinfo>` synopsis

```
namespace std {
  class type_info;
  class bad_cast;
  class bad_typeid;
}
```

See also: 5.1295.1, 5.1393.1.

18.227.1 Class `type_info` [type.info]

```
namespace std {
  class type_info {
  public:
    virtual ~type_info();
    bool operator==(const type_info& rhs) const noexcept;
    bool operator!=(const type_info& rhs) const noexcept;
    bool before(const type_info& rhs) const noexcept;
    size_t hash_code() const noexcept;
    const char* name() const noexcept;

    type_info(const type_info& rhs) = delete;            // cannot be copied
    type_info& operator=(const type_info& rhs) = delete; // cannot be copied
  };
}
```

1

The class `type_info` describes type information generated by the implementation. Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for

equality or collating order. The names, encoding rule, and collating sequence for types are all unspecified and may differ between programs.

```
bool operator==(const type_info& rhs) const noexcept;
```

1 *Effects:* Compares the current object with `rhs`.

1 *Returns:* `true` if the two values describe the same type.

```
bool operator!=(const type_info& rhs) const noexcept;
```

1 *Returns:* `!(*this == rhs)`.

```
bool before(const type_info& rhs) const noexcept;
```

2 *Effects:* Compares the current object with `rhs`.

3 *Returns:* `true` if `*this` precedes `rhs` in the implementation's collation order.

```
size_t hash_code() const noexcept;
```

4 *Returns:* An unspecified value, except that within a single execution of the program, it shall return the same value for any two `type_info` objects which compare equal.

1 *Remark:* an implementation should return different values for two `type_info` objects which do not compare equal.

```
const char* name() const noexcept;
```

1 *Returns:* An implementation-defined NTBS.

2 *Remarks:* The message may be a null-terminated multibyte string (17.26.0.0.0.1), suitable for conversion and display as a `wstring` (21.26, 22.34.0.1)

18.240.1 Class `bad_cast` [bad.cast]

```
namespace std {
  class bad_cast : public exception {
  public:
    bad_cast() noexcept;
    bad_cast(const bad_cast&) noexcept;
    bad_cast& operator=(const bad_cast&) noexcept;
    virtual const char* what() const noexcept;
  };
}
```

1 The class `bad_cast` defines the type of objects thrown as exceptions by the implementation to report the execution of an invalid *dynamic-cast* expression (5.1295.1).

```
bad_cast() noexcept;
```

2 *Effects:* Constructs an object of class `bad_cast`.

3 *Remarks:* The result of calling `what()` on the newly constructed object is implementation-defined.

```
bad_cast(const bad_cast&) noexcept;
bad_cast& operator=(const bad_cast&) noexcept;
```

4 *Effects:* Copies an object of class `bad_cast`.

```
virtual const char* what() const noexcept;
```

5 *Returns:* An implementation-defined NTBS.

6 *Remarks:* The message may be a null-terminated multibyte string (17.26.0.0.0.1), suitable for conversion and display as a `wstring` (21.26, 22.34.0.1)

18.240.2 Class `bad_typeid` [bad.typeid]

```
namespace std {
  class bad_typeid : public exception {
  public:
    bad_typeid() noexcept;
    bad_typeid(const bad_typeid&) noexcept;
    bad_typeid& operator=(const bad_typeid&) noexcept;
    virtual const char* what() const noexcept;
  };
}
```

1 The class `bad_typeid` defines the type of objects thrown as exceptions by the implementation to report a null pointer in a *typeid* expression (5.1393.1).

```
bad_typeid() noexcept;
```

2 *Effects:* Constructs an object of class `bad_typeid`.

3 *Remarks:* The result of calling `what()` on the newly constructed object is implementation-defined.

```
bad_typeid(const bad_typeid&) noexcept;
bad_typeid& operator=(const bad_typeid&) noexcept;
```

4 *Effects:* Copies an object of class `bad_typeid`.

```
virtual const char* what() const noexcept;
```

5 *Returns:* An implementation-defined NTBS.

6 *Remarks:* The message may be a null-terminated multibyte string (17.26.0.0.0.1), suitable for conversion and display as a `wstring` (21.26, 22.34.0.1)

18.241 Exception handling [support.exception]

1 The header `<exception>` defines several types and functions related to the handling of exceptions in a C++ program.

Header `<exception>` synopsis

```
namespace std {
  class exception;
  class bad_exception;
  class nested_exception;

  typedef void (*unexpected_handler)();
  unexpected_handler get_unexpected() noexcept;
  unexpected_handler set_unexpected(unexpected_handler f) noexcept;
  [[noreturn]] void unexpected();
```

```
  typedef void (*terminate_handler)();
  terminate_handler get_terminate() noexcept;
  terminate_handler set_terminate(terminate_handler f) noexcept;
  [[noreturn]] void terminate() noexcept;

  bool uncaught_exception() noexcept;

  typedef unspecified  exception_ptr;

  exception_ptr current_exception() noexcept;
  [[noreturn]] void rethrow_exception(exception_ptr p);
  template<class E> exception_ptr make_exception_ptr(E e) noexcept;

  template <class T> [[noreturn]] void throw_with_nested(T&& t);
  template <class E> void rethrow_if_nested(const E& e);
}
```

See also: 15.308.

18.241.1 Class `exception` [exception]

```
namespace std {
  class exception {
  public:
    exception() noexcept;
    exception(const exception&) noexcept;
    exception& operator=(const exception&) noexcept;
    virtual ~exception();
    virtual const char* what() const noexcept;
  };
}
```

1 The class `exception` defines the base class for the types of objects thrown as exceptions by C++ standard library components, and certain expressions, to report errors detected during program execution.

2 Each standard library class `T` that derives from class `exception` shall have a publicly accessible copy constructor and a publicly accessible copy assignment operator that do not exit with an exception. These member functions shall meet the following postcondition: If two objects `lhs` and `rhs` both have dynamic type `T` and `lhs` is a copy of `rhs`, then `strcmp(lhs.what(), rhs.what())` shall equal 0.

`exception() noexcept;`

1 *Effects:* Constructs an object of class `exception`.

```
exception(const exception& rhs) noexcept;
exception& operator=(const exception& rhs) noexcept;
```

2 *Effects:* Copies an `exception` object.

3 *Postcondition:* If `*this` and `rhs` both have dynamic type `exception` then `strcmp(what(), rhs.what())` shall equal 0.

`virtual ~exception();`

4 *Effects:* Destroys an object of class `exception`.

`virtual const char* what() const noexcept;`

5 *Returns:* An implementation-defined NTBS.

6 *Remarks:* The message may be a null-terminated multibyte string (17.26.0.0.0.1), suitable for conversion and display as a `wstring` (21.26, 22.34.0.1). The return value remains valid until the exception object from which it is obtained is destroyed or a non-`const` member function of the exception object is called.

18.247.1 Class `bad_exception` [bad.exception]

```
namespace std {
  class bad_exception : public exception {
  public:
    bad_exception() noexcept;
    bad_exception(const bad_exception&) noexcept;
    bad_exception& operator=(const bad_exception&) noexcept;
    virtual const char* what() const noexcept;
  };
}
```

1 The class `bad_exception` defines the type of objects thrown as described in (15.370.1).

`bad_exception() noexcept;`

2 *Effects:* Constructs an object of class `bad_exception`.

3 *Remarks:* The result of calling `what()` on the newly constructed object is implementation-defined.

```
bad_exception(const bad_exception&) noexcept;
bad_exception& operator=(const bad_exception&) noexcept;
```

4 *Effects:* Copies an object of class `bad_exception`.

`virtual const char* what() const noexcept;`

5 *Returns:* An implementation-defined NTBS.

6 *Remarks:* The message may be a null-terminated multibyte string (17.26.0.0.0.1), suitable for conversion and display as a `wstring` (21.26, 22.34.0.1).

18.247.2 Abnormal termination [exception.terminate]

18.247.2.1 Type `terminate_handler` [terminate.handler]

`typedef void (*terminate_handler)();`

1 The type of a *handler function* to be called by `std::terminate()` when terminating exception processing.

2 *Required behavior:* A `terminate_handler` shall terminate execution of the program without returning to the caller.

1 *Default behavior:* The implementation's default `terminate_handler` calls `abort()`.

18.250.0.1 `set_terminate` [set.terminate]

```
terminate_handler set_terminate(terminate_handler f) noexcept;
```

1 *Effects:* Establishes the function designated by `f` as the current handler function for terminating exception processing.

1 *Remarks:* It is unspecified whether a null pointer value designates the default `terminate_handler`.

2 *Returns:* The previous `terminate_handler`.

18.251.0.1 `get_terminate` [get.terminate]

```
terminate_handler get_terminate() noexcept;
```

1 *Returns:* The current `terminate_handler`. [*Note:* This may be a null pointer value. — *end note*]

18.251.0.2 `terminate` [terminate]

```
[[noreturn]] void terminate() noexcept;
```

1 *Remarks:* Called by the implementation when exception handling must be abandoned for any of several reasons (15.308.1), in effect immediately after throwing the exception. May also be called directly by the program.

1 *Effects:* Calls the current `terminate_handler` function. [*Note:* A default `terminate_handler` is always considered a callable handler in this context. — *end note*]

18.253.1 `uncaught_exception` [uncaught]

```
bool uncaught_exception() noexcept;
```

1 *Returns:* `true` after the current thread has initialized an exception object (15.7) until a handler for the exception (including `std::unexpected()` or `std::terminate()`) is activated (15.146). [*Note:* This includes stack unwinding (15.89). — *end note*]

2 *Remarks:* When `uncaught_exception()` returns `true`, throwing an exception can result in a call of `std::terminate()` (15.308.1).

18.254.1 Exception propagation [propagation]

```
typedef unspecified  exception_ptr;
```

1 The type exception_ptr can be used to refer to an exception object.

1 `exception_ptr` shall satisfy the requirements of `NullablePointer` (17.153.0.1).

1 Two non-null values of type `exception_ptr` are equivalent and compare equal if and only if they refer to the same exception.

1 The default constructor of `exception_ptr` produces the null value of the type.

1

`exception_ptr` shall not be implicitly convertible to any arithmetic, enumeration, or pointer type.

1

[*Note:* An implementation might use a reference-counted smart pointer as `exception_ptr`. — *end note*]

1

For purposes of determining the presence of a data race, operations on `exception_ptr` objects shall access and modify only the `exception_ptr` objects themselves and not the exceptions they refer to. Use of `rethrow_exception` on `exception_ptr` objects that refer to the same exception object shall not introduce a data race. [*Note:* if `rethrow_exception` rethrows the same exception object (rather than a copy), concurrent access to that rethrown exception object may introduce a data race. Changes in the number of `exception_ptr` objects that refer to a particular exception do not introduce a data race. — *end note*]

```
exception_ptr current_exception() noexcept;
```

1

Returns: An `exception_ptr` object that refers to the currently handled exception (15.146) or a copy of the currently handled exception, or a null `exception_ptr` object if no exception is being handled. The referenced object shall remain valid at least as long as there is an `exception_ptr` object that refers to it. If the function needs to allocate memory and the attempt fails, it returns an `exception_ptr` object that refers to an instance of `bad_alloc`. It is unspecified whether the return values of two successive calls to `current_exception` refer to the same exception object. [*Note:* That is, it is unspecified whether `current_exception` creates a new copy each time it is called. — *end note*] If the attempt to copy the current exception object throws an exception, the function returns an `exception_ptr` object that refers to the thrown exception or, if this is not possible, to an instance of `bad_exception`. [*Note:* The copy constructor of the thrown exception may also fail, so the implementation is allowed to substitute a `bad_exception` object to avoid infinite recursion. — *end note*]

```
[[noreturn]] void rethrow_exception(exception_ptr p);
```

1 *Requires:* `p` shall not be a null pointer.

2 *Throws:* the exception object to which `p` refers.

```
template<class E> exception_ptr make_exception_ptr(E e) noexcept;
```

3 *Effects:* Creates an `exception_ptr` object that refers to a copy of `e`, as if

```
try {
  throw e;
} catch(...) {
  return current_exception();
}
```

4 [*Note:* This function is provided for convenience and efficiency reasons. — *end note*]

18.265.1 `nested_exception` [except.nested]

```
namespace std {
  class nested_exception {
  public:
    nested_exception() noexcept;
    nested_exception(const nested_exception&) noexcept = default;
```

```
    nested_exception& operator=(const nested_exception&) noexcept = default;
    virtual ~nested_exception() = default;

    // access functions
    [[noreturn]] void rethrow_nested() const;
    exception_ptr nested_ptr() const noexcept;
  };

  template<class T> [[noreturn]] void throw_with_nested(T&& t);
  template <class E> void rethrow_if_nested(const E& e);
}
```

1 The class `nested_exception` is designed for use as a mixin through multiple inheritance. It captures the currently handled exception and stores it for later use.

2 [*Note:* `nested_exception` has a virtual destructor to make it a polymorphic class. Its presence can be tested for with `dynamic_cast`. — *end note*]

`nested_exception() noexcept;`

1 *Effects:* The constructor calls `current_exception()` and stores the returned value.

`[[noreturn]] void rethrow_nested() const;`

2 *Effects:* If `nested_ptr()` returns a null pointer, the function calls `std::terminate()`. Otherwise, it throws the stored exception captured by `*this`.

`exception_ptr nested_ptr() const noexcept;`

3 *Returns:* The stored exception captured by this `nested_exception` object.

`template <class T> [[noreturn]] void throw_with_nested(T&& t);`

1 Let `U` be `remove_reference_t<T>`.

2 *Requires:* `U` shall be `CopyConstructible`.

3 *Throws:* if `U` is a non-union class type not derived from `nested_exception`, an exception of unspecified type that is publicly derived from both `U` and `nested_exception` and constructed from `std::forward<T>(t)`, otherwise `std::forward<T>(t)`.

`template <class E> void rethrow_if_nested(const E& e);`

1 *Effects:* If the dynamic type of `e` is publicly and unambiguously derived from `nested_exception`, calls `dynamic_cast<const nested_exception&>(e).rethrow_nested()`.

18.274 Initializer lists [support.initlist]

1 The header `<initializer_list>` defines a class template and several support functions related to list-initialization (see 8.2435.1).

Header `<initializer_list>` synopsis

```
namespace std {
  template<class E> class initializer_list {
  public:
```

```
    typedef E value_type;
    typedef const E& reference;
    typedef const E& const_reference;
    typedef size_t size_type;

    typedef const E* iterator;
    typedef const E* const_iterator;

    constexpr initializer_list() noexcept;

    constexpr size_t size() const noexcept;       // number of elements
    constexpr const E* begin() const noexcept;    // first element
    constexpr const E* end() const noexcept;      // one past the last element
  };

  // 18.294.3 initializer list range access
  template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;
  template<class E> constexpr const E* end(initializer_list<E> il) noexcept;
}
```

2 An object of type `initializer_list<E>` provides access to an array of objects of type `const E`. [*Note:* A pair of pointers or a pointer plus a length would be obvious representations for `initializer_list`. `initializer_list` is used to implement initializer lists as specified in 8.2435.1. Copying an initializer list does not copy the underlying elements. — *end note*]

18.294.1 Initializer list constructors [support.initlist.cons]

`constexpr initializer_list() noexcept;`

1 *Effects:* constructs an empty `initializer_list` object.

2 *Postcondition:* `size() == 0`

18.294.2 Initializer list access [support.initlist.access]

`constexpr const E* begin() const noexcept;`

1 *Returns:* A pointer to the beginning of the array. If `size() == 0` the values of `begin()` and `end()` are unspecified but they shall be identical.

`constexpr const E* end() const noexcept;`

2 *Returns:* `begin() + size()`

`constexpr size_t size() const noexcept;`

3 *Returns:* The number of elements in the array.

4 *Complexity:* Constant time.

18.294.3 Initializer list range access [support.initlist.range]

`template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;`

1 *Returns:* `il.begin()`.

`template<class E> constexpr const E* end(initializer_list<E> il) noexcept;`

2 *Returns:* `il.end()`.

18.295 Other runtime support [support.runtime]

1

Headers `<csetjmp>` (nonlocal jumps), `<csignal>` (signal handling), `<cstdalign> (alignment)`, `<cstdarg>` (variable arguments), `<cstdbool>` (`__bool_true_false_are_defined`). `<cstdlib>` (runtime environment `getenv()`, `system()`), and `<ctime>` (system clock `clock()`, `time()`) provide further compatibility with C code.

1

The contents of these headers are the same as the Standard C library headers `<setjmp.h>`, `<signal.h>`, `<stdalign.h>`, `<stdarg.h>`, `<stdbool.h>`, `<stdlib.h>`, and `<time.h>`, respectively, with the following changes:

1

The restrictions that ISO C places on the second parameter to the `va_start()` macro in header `<stdarg.h>` are different in this International Standard. The parameter `parmN` is the identifier of the rightmost parameter in the variable parameter list of the function definition (the one just before the `...`).[227] If the parameter `parmN` is of a reference type, or of a type that is not compatible with the type that results when passing an argument for which there is no parameter, the behavior is undefined.

See also: ISO C 4.8.1.1.

1

The function signature `longjmp(jmp_buf jbuf, int val)` has more restricted behavior in this International Standard. A `setjmp`/`longjmp` call pair has undefined behavior if replacing the `setjmp` and `longjmp` by `catch` and `throw` would invoke any non-trivial destructors for any automatic objects.

See also: ISO C 7.10.4, 7.8, 7.6, 7.12.

1

Calls to the function `getenv` shall not introduce a data race (17.607.0.1) provided that nothing modifies the environment. [*Note:* Calls to the POSIX functions `setenv` and `putenv` modify the environment. — *end note*]

1

A call to the `setlocale` function may introduce a data race with other calls to the `setlocale` function or with calls to functions that are affected by the current C locale. The implementation shall behave as if no library function other than `locale::global()` calls the `setlocale` function.

1

The header `<cstdalign>` and the header `<stdalign.h>` shall not define a macro named `alignas`.

1

The header `<cstdbool>` and the header `<stdbool.h>` shall not define macros named `bool`, `true`, or `false`.

1 A call to the function `signal` synchronizes with any resulting invocation of the signal handler so installed.

2

The common subset of the C and C++ languages consists of all declarations, definitions, and expressions that may appear in a well formed C++ program and also in a conforming C program. A POF ("plain old function") is a function that uses only features from this common subset, and that does not directly or indirectly use any function that is not a POF, except that it may use plain lock-free atomic operations. A *plain lock-free atomic operation* is an invocation of a function f from Clause 29, such that f is not a member function, and either f is the function `atomic_is_lock_free`, or for every atomic argument `A` passed to

227) Note that `va_start` is required to work as specified even if unary `operator&` is overloaded for the type of `parmN`.

f, `atomic_is_lock_free(A)` yields `true`. All signal handlers shall have C linkage. The behavior of any function other than a POF used as a signal handler in a C++ program is implementation-defined.[228]

Table 34 — Header `<csetjmp>` synopsis

Type	Name(s)

19 Diagnostics library [diagnostics]

19.1 General [diagnostics.general]

1

This Clause describes components that C++ programs may use to detect and report error conditions.

1 The following subclauses describe components for reporting several kinds of exceptional conditions, documenting program assertions, and a global variable for error number codes, as summarized in Table 41.

Table 41 — Diagnostics library summary

Subclause		Header(s)
19.3	Exception classes	`<stdexcept>`
19.8	Assertions	`<cassert>`
19.12	Error numbers	`<cerrno>`
19.14	System error support	`<system_error>`

19.3 Exception classes [std.exceptions]

1 The Standard C++ library provides classes to be used to report certain errors (17.677.0.1) in C++ programs. In the error model reflected in these classes, errors are divided into two broad categories: *logic* errors and *runtime* errors.

2 The distinguishing characteristic of logic errors is that they are due to errors in the internal logic of the program. In theory, they are preventable.

3 By contrast, runtime errors are due to events beyond the scope of the program. They cannot be easily predicted in advance. The header `<stdexcept>` defines several types of predefined exceptions for reporting errors in a C++ program. These exceptions are related by inheritance.

Header `<stdexcept>` synopsis

```
namespace std {
  class logic_error;
    class domain_error;
    class invalid_argument;
    class length_error;
    class out_of_range;
  class runtime_error;
    class range_error;
    class overflow_error;
    class underflow_error;
}
```

19.3.1 Class `logic_error` [logic.error]

```
namespace std {
  class logic_error : public exception {
  public:
    explicit logic_error(const string& what_arg);
    explicit logic_error(const char* what_arg);
```

```
  };
}
```

1 The class `logic_error` defines the type of objects thrown as exceptions to report errors presumably detectable before the program executes, such as violations of logical preconditions or class invariants.

`logic_error(const string& what_arg);`

2 *Effects:* Constructs an object of class `logic_error`.

3 *Postcondition:* `strcmp(what(), what_arg.c_str()) == 0`.

`logic_error(const char* what_arg);`

4 *Effects:* Constructs an object of class `logic_error`.

5 *Postcondition:* `strcmp(what(), what_arg) == 0`.

19.3.2 Class `domain_error` [domain.error]

```
namespace std {
  class domain_error : public logic_error {
  public:
    explicit domain_error(const string& what_arg);
    explicit domain_error(const char* what_arg);
  };
}
```

1 The class `domain_error` defines the type of objects thrown as exceptions by the implementation to report domain errors.

`domain_error(const string& what_arg);`

2 *Effects:* Constructs an object of class `domain_error`.

3 *Postcondition:* `strcmp(what(), what_arg.c_str()) == 0`.

`domain_error(const char* what_arg);`

4 *Effects:* Constructs an object of class `domain_error`.

5 *Postcondition:* `strcmp(what(), what_arg) == 0`.

19.3.3 Class `invalid_argument` [invalid.argument]

```
namespace std {
  class invalid_argument : public logic_error {
  public:
    explicit invalid_argument(const string& what_arg);
    explicit invalid_argument(const char* what_arg);
  };
}
```

1 The class `invalid_argument` defines the type of objects thrown as exceptions to report an invalid argument.

`invalid_argument(const string& what_arg);`

2 *Effects:* Constructs an object of class `invalid_argument`.

3 *Postcondition:* `strcmp(what(), what_arg.c_str()) == 0`.

`invalid_argument(const char* what_arg);`

4 *Effects:* Constructs an object of class `invalid_argument`.

5 *Postcondition:* `strcmp(what(), what_arg) == 0`.

19.3.4 Class `length_error` [length.error]

```
namespace std {
  class length_error : public logic_error {
  public:
    explicit length_error(const string& what_arg);
    explicit length_error(const char* what_arg);
  };
}
```

1

The class `length_error` defines the type of objects thrown as exceptions to report an attempt to produce an object whose length exceeds its maximum allowable size.

`length_error(const string& what_arg);`

1 *Effects:* Constructs an object of class `length_error`.

2 *Postcondition:* `strcmp(what(), what_arg.c_str()) == 0`.

`length_error(const char* what_arg);`

3 *Effects:* Constructs an object of class `length_error`.

4 *Postcondition:* `strcmp(what(), what_arg) == 0`.

19.4.1 Class `out_of_range` [out.of.range]

```
namespace std {
  class out_of_range : public logic_error {
  public:
    explicit out_of_range(const string& what_arg);
    explicit out_of_range(const char* what_arg);
  };
}
```

1

The class `out_of_range` defines the type of objects thrown as exceptions to report an argument value not in its expected range.

`out_of_range(const string& what_arg);`

1 *Effects:* Constructs an object of class `out_of_range`.

2 *Postcondition:* `strcmp(what(), what_arg.c_str()) == 0`.

`out_of_range(const char* what_arg);`

3 *Effects:* Constructs an object of class `out_of_range`.

4 *Postcondition:* `strcmp(what(), what_arg) == 0`.

19.5.1 Class `runtime_error` [runtime.error]

```
namespace std {
  class runtime_error : public exception {
  public:
    explicit runtime_error(const string& what_arg);
    explicit runtime_error(const char* what_arg);
  };
}
```

1 The class `runtime_error` defines the type of objects thrown as exceptions to report errors presumably detectable only when the program executes.

`runtime_error(const string& what_arg);`

2

Effects: Constructs an object of class `runtime_error`.

1 *Postcondition:* `strcmp(what(), what_arg.c_str()) == 0`.

`runtime_error(const char* what_arg);`

2 *Effects:* Constructs an object of class `runtime_error`.

3 *Postcondition:* `strcmp(what(), what_arg) == 0`.

19.6.1 Class `range_error` [range.error]

```
namespace std {
  class range_error : public runtime_error {
  public:
    explicit range_error(const string& what_arg);
    explicit range_error(const char* what_arg);
  };
}
```

1

The class `range_error` defines the type of objects thrown as exceptions to report range errors in internal computations.

`range_error(const string& what_arg);`

1 *Effects:* Constructs an object of class `range_error`.

2 *Postcondition:* `strcmp(what(), what_arg.c_str()) == 0`.

`range_error(const char* what_arg);`

3 *Effects:* Constructs an object of class `range_error`.

4 *Postcondition:* `strcmp(what(), what_arg) == 0`.

19.7.1 Class `overflow_error` [overflow.error]

```
namespace std {
  class overflow_error : public runtime_error {
  public:
    explicit overflow_error(const string& what_arg);
    explicit overflow_error(const char* what_arg);
  };
}
```

1 The class `overflow_error` defines the type of objects thrown as exceptions to report an arithmetic overflow error.

`overflow_error(const string& what_arg);`

2 *Effects:* Constructs an object of class `overflow_error`.

3 *Postcondition:* `strcmp(what(), what_arg.c_str()) == 0`.

`overflow_error(const char* what_arg);`

4 *Effects:* Constructs an object of class `overflow_error`.

5 *Postcondition:* `strcmp(what(), what_arg) == 0`.

19.7.2 Class `underflow_error` [underflow.error]

```
namespace std {
  class underflow_error : public runtime_error {
  public:
    explicit underflow_error(const string& what_arg);
    explicit underflow_error(const char* what_arg);
  };
}
```

1 The class `underflow_error` defines the type of objects thrown as exceptions to report an arithmetic underflow error.

`underflow_error(const string& what_arg);`

2 *Effects:* Constructs an object of class `underflow_error`.

3 *Postcondition:* `strcmp(what(), what_arg.c_str()) == 0`.

`underflow_error(const char* what_arg);`

4 *Effects:* Constructs an object of class `underflow_error`.

5 *Postcondition:* `strcmp(what(), what_arg) == 0`.

19.8 Assertions [assertions]

1

The header `<cassert>`, described in (Table 42), provides a macro for documenting C++ program assertions and a mechanism for disabling the assertion checks.

Table 42 — Header `<cassert>` synopsis

Type	Name(s)
Macro:	`assert`

1

The contents are the same as the Standard C library header `<assert.h>`.

See also: ISO C 7.2.

19.12 Error numbers [errno]

1

The header `<cerrno>` is described in Table 43. Its contents are the same as the POSIX header `<errno.h>`, except that `errno` shall be defined as a macro. [*Note:* The intent is to remain in close alignment with the POSIX standard. — *end note*] A separate `errno` value shall be provided for each thread.

19.14 System error support [syserr]

1

This subclause describes components that the standard library and C++ programs may use to report error conditions originating from the operating system or other low-level application program interfaces.

Table 43 — Header `<cerrno>` synopsis

Type	Name(s)				
Macros:	ECONNREFUSED	EIO	ENODEV	ENOTEMPTY	ERANGE
E2BIG	ECONNRESET	EISCONN	ENOENT	ENOTRECOVERABLE	EROFS
EACCES	EDEADLK	EISDIR	ENOEXEC	ENOTSOCK	ESPIPE
EADDRINUSE	EDESTADDRREQ	ELOOP	ENOLCK	ENOTSUP	ESRCH
EADDRNOTAVAIL	EDOM	EMFILE	ENOLINK	ENOTTY	ETIME
EAFNOSUPPORT	EEXIST	EMLINK	ENOMEM	ENXIO	ETIMEDOUT
EAGAIN	EFAULT	EMSGSIZE	ENOMSG	EOPNOTSUPP	ETXTBSY
EALREADY	EFBIG	ENAMETOOLONG	ENOPROTOOPT	EOVERFLOW	EWOULDBLOCK
EBADF	EHOSTUNREACH	ENETDOWN	ENOSPC	EOWNERDEAD	EXDEV
EBADMSG	EIDRM	ENETRESET	ENOSR	EPERM	errno
EBUSY	EILSEQ	ENETUNREACH	ENOSTR	EPIPE	
ECANCELED	EINPROGRESS	ENFILE	ENOSYS	EPROTO	
ECHILD	EINTR	ENOBUFS	ENOTCONN	EPROTONOSUPPORT	
ECONNABORTED	EINVAL	ENODATA	ENOTDIR	EPROTOTYPE	

1 Components described in this subclause shall not change the value of `errno` (19.12). Implementations should leave the error states provided by other libraries unchanged.

Header `<system_error>` synopsis

```
namespace std {
  class error_category;
  const error_category& generic_category() noexcept;
  const error_category& system_category() noexcept;

  class error_code;
  class error_condition;
  class system_error;

  template <class T>
  struct is_error_code_enum : public false_type {};

  template <class T>
  struct is_error_condition_enum : public false_type {};

  enum class errc {
    address_family_not_supported,       // EAFNOSUPPORT

  template <class T> struct hash;
  template <> struct hash<error_code>;
}  // namespace std
```

2 The value of each `enum errc` constant shall be the same as the value of the `<cerrno>` macro shown in the above synopsis. Whether or not the `<system_error>` implementation exposes the `<cerrno>` macros is unspecified.

1 The `is_error_code_enum` and `is_error_condition_enum` may be specialized for user-defined types to indicate that such types are eligible for `class error_code` and `class error_condition` automatic conversions, respectively.

19.16.1 Class `error_category` [syserr.errcat]

19.16.1.1 Class `error_category` overview [syserr.errcat.overview]

1 The class `error_category` serves as a base class for types used to identify the source and encoding of a particular category of error code. Classes may be derived from `error_category` to support categories of errors in addition to those defined in this International Standard. Such classes shall behave as specified in this subclause. [*Note:* `error_category` objects are passed by reference, and two such objects are equal if they have the same address. This means that applications using custom `error_category` types should create a single object of each such type. — *end note*]

```
namespace std {
  class error_category {
  public:
    constexpr error_category() noexcept;
    virtual ~error_category();
    error_category(const error_category&) = delete;
    error_category& operator=(const error_category&) = delete;
    virtual const char* name() const noexcept = 0;
```

```
    virtual error_condition default_error_condition(int ev) const noexcept;
    virtual bool equivalent(int code, const error_condition& condition) const noexcept;
    virtual bool equivalent(const error_code& code, int condition) const noexcept;
    virtual string message(int ev) const = 0;

    bool operator==(const error_category& rhs) const noexcept;
    bool operator!=(const error_category& rhs) const noexcept;
    bool operator<(const error_category& rhs) const noexcept;
  };

  const error_category& generic_category() noexcept;
  const error_category& system_category() noexcept;

}   // namespace std
```

19.16.1.2 Class error_category virtual members [syserr.errcat.virtuals]

`virtual ~error_category();`

1 *Effects:* Destroys an object of class `error_category`.

`virtual const char* name() const noexcept = 0;`

1 *Returns:* A string naming the error category.

`virtual error_condition default_error_condition(int ev) const noexcept;`

2 *Returns:* `error_condition(ev, *this)`.

`virtual bool equivalent(int code, const error_condition& condition) const noexcept;`

3 *Returns:* `default_error_condition(code) == condition`.

`virtual bool equivalent(const error_code& code, int condition) const noexcept;`

4 *Returns:* `*this == code.category() && code.value() == condition`.

`virtual string message(int ev) const = 0;`

5 *Returns:* A string that describes the error condition denoted by `ev`.

19.19.0.1 Class error_category non-virtual members [syserr.errcat.nonvirtuals]

`constexpr error_category() noexcept;`

1 *Effects:* Constructs an object of class `error_category`.

`bool operator==(const error_category& rhs) const noexcept;`

2 *Returns:* `this == &rhs`.

`bool operator!=(const error_category& rhs) const noexcept;`

3 *Returns:* `!(*this == rhs)`.

`bool operator<(const error_category& rhs) const noexcept;`

4 *Returns:* `less<const error_category*>()(this, &rhs)`.

[*Note:* `less` (20.339.3) provides a total ordering for pointers. — *end note*]

19.19.0.2 Program defined classes derived from `error_category` [syserr.errcat.derived]

`virtual const char* name() const noexcept = 0;`

1 *Returns:* A string naming the error category.

`virtual error_condition default_error_condition(int ev) const noexcept;`

2 *Returns:* An object of type `error_condition` that corresponds to `ev`.

`virtual bool equivalent(int code, const error_condition& condition) const noexcept;`

3 *Returns:* `true` if, for the category of error represented by `*this`, `code` is considered equivalent to `condition`; otherwise, `false`.

`virtual bool equivalent(const error_code& code, int condition) const noexcept;`

4 *Returns:* `true` if, for the category of error represented by `*this`, `code` is considered equivalent to `condition`; otherwise, `false`.

19.19.0.3 Error category objects [syserr.errcat.objects]

`const error_category& generic_category() noexcept;`

1 *Returns:* A reference to an object of a type derived from class `error_category`. All calls to this function shall return references to the same object.

2 *Remarks:* The object's `default_error_condition` and `equivalent` virtual functions shall behave as specified for the class `error_category`. The object's `name` virtual function shall return a pointer to the string `"generic"`.

`const error_category& system_category() noexcept;`

3 *Returns:* A reference to an object of a type derived from class `error_category`. All calls to this function shall return references to the same object.

4 *Remarks:* The object's `equivalent` virtual functions shall behave as specified for class `error_category`. The object's `name` virtual function shall return a pointer to the string `"system"`. The object's `default_error_condition` virtual function shall behave as follows:

If the argument `ev` corresponds to a POSIX `errno` value `posv`, the function shall return `error_condition(posv, generic_category())`. Otherwise, the function shall return `error_condition(ev, system_category())`. What constitutes correspondence for any given operating system is unspecified. [*Note:* The number of potential system error codes is large and unbounded, and some may not correspond to any POSIX `errno` value. Thus implementations are given latitude in determining correspondence. — *end note*]

19.22.1 Class `error_code` [syserr.errcode]

19.22.1.1 Class `error_code` overview [syserr.errcode.overview]

1 The class `error_code` describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces. [*Note:* Class `error_code` is an adjunct to error reporting by exception. — *end note*]

```
namespace std {
  class error_code {
  public:
    // 19.22.1.2 constructors:
```

```
    error_code() noexcept;
    error_code(int val, const error_category& cat) noexcept;
    template <class ErrorCodeEnum>
      error_code(ErrorCodeEnum e) noexcept;

    // 19.23.0.1 modifiers:
    void assign(int val, const error_category& cat) noexcept;
    template <class ErrorCodeEnum>
        error_code& operator=(ErrorCodeEnum e) noexcept;
    void clear() noexcept;

    // 19.23.0.2 observers:
    int value() const noexcept;
    const error_category& category() const noexcept;
    error_condition default_error_condition() const noexcept;
    string message() const;
    explicit operator bool() const noexcept;

  private:
    int val_;                    // exposition only
    const error_category* cat_; // exposition only
  };

  // 19.24.0.1 non-member functions:
  error_code make_error_code(errc e) noexcept;
  bool operator<(const error_code& lhs, const error_code& rhs) noexcept;

  template <class charT, class traits>
    basic_ostream<charT,traits>&
      operator<<(basic_ostream<charT,traits>& os, const error_code& ec);
}   // namespace std
```

19.22.1.2 Class `error_code` constructors [syserr.errcode.constructors]

`error_code() noexcept;`

1 *Effects:* Constructs an object of type `error_code`.

2 *Postconditions:* `val_ == 0` and `cat_ == &system_category()`.

`error_code(int val, const error_category& cat) noexcept;`

3 *Effects:* Constructs an object of type `error_code`.

4 *Postconditions:* `val_ == val` and `cat_ == &cat`.

```
template <class ErrorCodeEnum>
  error_code(ErrorCodeEnum e) noexcept;
```

5 *Effects:* Constructs an object of type `error_code`.

6 *Postconditions:* `*this == make_error_code(e)`.

7 *Remarks:* This constructor shall not participate in overload resolution unless `is_error_code_enum<ErrorCodeEnum>::value` is `true`.

19.23.0.1 Class error_code modifiers [syserr.errcode.modifiers]

```
void assign(int val, const error_category& cat) noexcept;
```

1 *Postconditions:* `val_ == val` and `cat_ == &cat`.

```
template <class ErrorCodeEnum>
    error_code& operator=(ErrorCodeEnum e) noexcept;
```

2 *Postconditions:* `*this == make_error_code(e)`.

3 *Returns:* `*this`.

4 *Remarks:* This operator shall not participate in overload resolution unless `is_error_code_enum<ErrorCodeEnum>::value` is `true`.

```
void clear() noexcept;
```

5 *Postconditions:* `value() == 0` and `category() == system_category()`.

19.23.0.2 Class error_code observers [syserr.errcode.observers]

```
int value() const noexcept;
```

1 *Returns:* `val_`.

```
const error_category& category() const noexcept;
```

2 *Returns:* `*cat_`.

```
error_condition default_error_condition() const noexcept;
```

3 *Returns:* `category().default_error_condition(value())`.

```
string message() const;
```

4

Returns: `category().message(value())`.

```
explicit operator bool() const noexcept;
```

1 *Returns:* `value() != 0`.

19.24.0.1 Class error_code non-member functions [syserr.errcode.nonmembers]

```
error_code make_error_code(errc e) noexcept;
```

1 *Returns:* `error_code(static_cast<int>(e), generic_category())`.

```
bool operator<(const error_code& lhs, const error_code& rhs) noexcept;
```

2 *Returns:* `lhs.category() < rhs.category() || lhs.category() == rhs.category() && lhs.value() < rhs.value()`.

```
template <class charT, class traits>
  basic_ostream<charT,traits>&
    operator<<(basic_ostream<charT,traits>& os, const error_code& ec);
```

3 *Effects:* `os << ec.category().name() << ':'  << ec.value()`.

19.24.1 Class error_condition [syserr.errcondition]

19.24.1.1 Class error_condition overview [syserr.errcondition.overview]

1 The class error_condition describes an object used to hold values identifying error conditions. [*Note:* error_condition values are portable abstractions, while error_code values (19.22.1) are implementation specific. — *end note*]

```
namespace std {
  class error_condition {
  public:
    // 19.24.1.2 constructors:
    error_condition() noexcept;
    error_condition(int val, const error_category& cat) noexcept;
    template <class ErrorConditionEnum>
      error_condition(ErrorConditionEnum e) noexcept;

    // 19.24.1.3 modifiers:
    void assign(int val, const error_category& cat) noexcept;
    template<class ErrorConditionEnum>
        error_condition& operator=(ErrorConditionEnum e) noexcept;
    void clear() noexcept;

    // 19.24.1.4 observers:
    int value() const noexcept;
    const error_category& category() const noexcept;
    string message() const;
    explicit operator bool() const noexcept;

  private:
    int val_;                    // exposition only
    const error_category* cat_;  // exposition only
  };

  // 19.24.1.5 non-member functions:
  bool operator<(const error_condition& lhs, const error_condition& rhs) noexcept;
} // namespace std
```

19.24.1.2 Class error_condition constructors [syserr.errcondition.constructors]

`error_condition() noexcept;`

1 *Effects:* Constructs an object of type error_condition.

2 *Postconditions:* val_ == 0 and cat_ == &generic_category().

`error_condition(int val, const error_category& cat) noexcept;`

3 *Effects:* Constructs an object of type error_condition.

4 *Postconditions:* val_ == val and cat_ == &cat.

```
template <class ErrorConditionEnum>
  error_condition(ErrorConditionEnum e) noexcept;
```

5 *Effects:* Constructs an object of type error_condition.

6 *Postcondition:* *this == make_error_condition(e).

7 *Remarks:* This constructor shall not participate in overload resolution unless is_error_condition_enum<ErrorConditionEnum>::value is true.

19.24.1.3 Class error_condition modifiers [syserr.errcondition.modifiers]

```
void assign(int val, const error_category& cat) noexcept;
```

1 *Postconditions:* `val_ == val` and `cat_ == &cat`.

```
template <class ErrorConditionEnum>
    error_condition& operator=(ErrorConditionEnum e) noexcept;
```

2 *Postcondition:* `*this == make_error_condition(e)`.

3 *Returns:* `*this`.

4 *Remarks:* This operator shall not participate in overload resolution unless `is_error_condition_enum<ErrorConditionEnum>::value` is `true`.

```
void clear() noexcept;
```

Postconditions: `value() == 0` and `category() == generic_category()`.

19.24.1.4 Class error_condition observers [syserr.errcondition.observers]

```
int value() const noexcept;
```

1 *Returns:* `val_`.

```
const error_category& category() const noexcept;
```

2 *Returns:* `*cat_`.

```
string message() const;
```

3 *Returns:* `category().message(value())`.

```
explicit operator bool() const noexcept;
```

4 *Returns:* `value() != 0`.

19.24.1.5 Class error_condition non-member functions [syserr.errcondition.nonmembers]

```
error_condition make_error_condition(errc e) noexcept;
```

Returns: `error_condition(static_cast<int>(e), generic_category())`.

```
bool operator<(const error_condition& lhs, const error_condition& rhs) noexcept;
```

1 *Returns:* `lhs.category() < rhs.category() || lhs.category() == rhs.category() && lhs.value() < rhs.value()`.

19.24.2 Comparison operators [syserr.compare]

```
bool operator==(const error_code& lhs, const error_code& rhs) noexcept;
```

1 *Returns:* `lhs.category() == rhs.category() && lhs.value() == rhs.value()`.

```
bool operator==(const error_code& lhs, const error_condition& rhs) noexcept;
```

2 *Returns:* `lhs.category().equivalent(lhs.value(), rhs) || rhs.category().equivalent(lhs, rhs.value())`.

```
bool operator==(const error_condition& lhs, const error_code& rhs) noexcept;
```

3 *Returns:* `rhs.category().equivalent(rhs.value(), lhs) || lhs.category().equivalent(rhs, lhs.value())`.

```
bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;
```

4 *Returns:* `lhs.category() == rhs.category() && lhs.value() == rhs.value()`.

```
bool operator!=(const error_code& lhs, const error_code& rhs) noexcept;
bool operator!=(const error_code& lhs, const error_condition& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_code& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;
```

5 *Returns:* `!(lhs == rhs)`.

19.24.3 System error hash support [syserr.hash]

```
template <> struct hash<error_code>;
```

1 The template specialization shall meet the requirements of class template `hash` (20.443.1).

19.24.4 Class `system_error` [syserr.syserr]

19.24.4.1 Class `system_error` overview [syserr.syserr.overview]

1

The class `system_error` describes an exception object used to report error conditions that have an associated error code. Such error conditions typically originate from the operating system or other low-level application program interfaces.

1 [*Note:* If an error represents an out-of-memory condition, implementations are encouraged to throw an exception object of type `bad_alloc` 18.223.1.1 rather than `system_error`. — *end note*]

```
namespace std {
  class system_error : public runtime_error {
  public:
    system_error(error_code ec, const string& what_arg);
    system_error(error_code ec, const char* what_arg);
    system_error(error_code ec);
    system_error(int ev, const error_category& ecat,
        const string& what_arg);
    system_error(int ev, const error_category& ecat,
        const char* what_arg);
    system_error(int ev, const error_category& ecat);
    const error_code& code() const noexcept;
    const char* what() const noexcept;
  };
}   // namespace std
```

19.25.0.1 Class `system_error` members [syserr.syserr.members]

```
system_error(error_code ec, const string& what_arg);
```

1 *Effects:* Constructs an object of class `system_error`.

2 *Postconditions:* `code() == ec`.

`string(what()).find(what_arg) != string::npos`.

```
system_error(error_code ec, const char* what_arg);
```

3 *Effects:* Constructs an object of class `system_error`.

4 *Postconditions:* `code() == ec`.

`string(what()).find(what_arg) != string::npos`.

```
system_error(error_code ec);
```

5 *Effects:* Constructs an object of class `system_error`.

6 *Postconditions:* `code() == ec`.

```
system_error(int ev, const error_category& ecat,
  const string& what_arg);
```

7 *Effects:* Constructs an object of class `system_error`.

8 *Postconditions:* `code() == error_code(ev, ecat)`.

`string(what()).find(what_arg) != string::npos`.

```
system_error(int ev, const error_category& ecat,
  const char* what_arg);
```

9 *Effects:* Constructs an object of class `system_error`.

10 *Postconditions:* `code() == error_code(ev, ecat)`.

`string(what()).find(what_arg) != string::npos`.

```
system_error(int ev, const error_category& ecat);
```

11 *Effects:* Constructs an object of class `system_error`.

12 *Postconditions:* `code() == error_code(ev, ecat)`.

```
const error_code& code() const noexcept;
```

13 *Returns:* `ec` or `error_code(ev, ecat)`, from the constructor, as appropriate.

```
const char* what() const noexcept;
```

14

Returns: An NTBS incorporating the arguments supplied in the constructor.

[*Note:* The returned NTBS might be the contents of `what_arg + ":  " + code.message()`. — *end note*]

20 General utilities library [utilities]

20.1 General [utilities.general]

1 This Clause describes utilities that are generally useful in C++ programs; some of these utilities are used by other elements of the C++ standard library. These utilities are summarized in Table 44.

Table 44 — General utilities library summary

Subclause		Header(s)
20.2	Utility components	`<utility>`
20.15	Pairs	`<utility>`
20.34	Tuples	`<tuple>`
20.66	Compile-time integer sequences	`<utility>`
20.68	Fixed-size sequences of bits	`<bitset>`

20.82	Memory	`<memory>`
		`<cstdlib>`
		`<cstring>`

20.127	Smart pointers	`<memory>`
20.283	Function objects	`<functional>`
20.449	Type traits	`<type_traits>`
20.575	Compile-time rational arithmetic	`<ratio>`
20.578	Time utilities	`<chrono>` `<ctime>`
20.606	Scoped allocators	`<scoped_allocator>`
20.610	Type indexes	`<typeindex>`

20.2 Utility components [utility]

1

This subclause contains some basic function and class templates that are used throughout the rest of the library.

Header `<utility>` synopsis

1 The header `<utility>` defines several types and function templates that are described in this Clause. It also defines the template `pair` and various function templates that operate on `pair` objects.

```
#include <initializer_list>

namespace std {
  // 20.3.1, operators:
  namespace rel_ops {
    template<class T> bool operator!=(const T&, const T&);
    template<class T> bool operator> (const T&, const T&);
    template<class T> bool operator<=(const T&, const T&);
    template<class T> bool operator>=(const T&, const T&);
  }

  // 20.3.2, swap:
```

```
template<class T> void swap(T& a, T& b) noexcept(see below);
template <class T, size_t N> void swap(T (&a)[N], T (&b)[N]) noexcept(noexcept(swap(*a, *b)));

// 20.4.1, exchange:
template <class T, class U=T> T exchange(T& obj, U&& new_val);

// 20.4.2, forward/move:
template <class T>
  constexpr T&& forward(remove_reference_t<T>& t) noexcept;
template <class T>
  constexpr T&& forward(remove_reference_t<T>&& t) noexcept;
template <class T>
  constexpr remove_reference_t<T>&& move(T&&) noexcept;
template <class T>
  constexpr conditional_t<
  !is_nothrow_move_constructible<T>::value && is_copy_constructible<T>::value,
  const T&, T&&> move_if_noexcept(T& x) noexcept;

// 20.11.1, declval:
template <class T>
  add_rvalue_reference_t<T> declval() noexcept;  // as unevaluated operand

// 20.15, pairs:
template <class T1, class T2> struct pair;

// 20.28.1, pair specialized algorithms:
template <class T1, class T2>
  constexpr bool operator==(const pair<T1,T2>&, const pair<T1,T2>&);
template <class T1, class T2>
  constexpr bool operator< (const pair<T1,T2>&, const pair<T1,T2>&);
template <class T1, class T2>
  constexpr bool operator!=(const pair<T1,T2>&, const pair<T1,T2>&);
template <class T1, class T2>
  constexpr bool operator> (const pair<T1,T2>&, const pair<T1,T2>&);
template <class T1, class T2>
  constexpr bool operator>=(const pair<T1,T2>&, const pair<T1,T2>&);
template <class T1, class T2>
  constexpr bool operator<=(const pair<T1,T2>&, const pair<T1,T2>&);
template <class T1, class T2>
  void swap(pair<T1,T2>& x, pair<T1,T2>& y) noexcept(noexcept(x.swap(y)));
template <class T1, class T2>
  constexpr see below make_pair(T1&&, T2&&);

// 20.33.1, tuple-like access to pair:
template <class T> class tuple_size;
template <size_t I, class T> class tuple_element;

template <class T1, class T2> struct tuple_size<pair<T1, T2> >;
template <class T1, class T2> struct tuple_element<0, pair<T1, T2> >;
template <class T1, class T2> struct tuple_element<1, pair<T1, T2> >;

template<size_t I, class T1, class T2>
  constexpr tuple_element_t<I, pair<T1, T2>>&
    get(pair<T1, T2>&) noexcept;
template<size_t I, class T1, class T2>
```

```
    constexpr tuple_element_t<I, pair<T1, T2>>&&
      get(pair<T1, T2>&&) noexcept;
  template<size_t I, class T1, class T2>
    constexpr const tuple_element_t<I, pair<T1, T2>>&
      get(const pair<T1, T2>&) noexcept;
  template <class T, class U>
    constexpr T& get(pair<T, U>& p) noexcept;
  template <class T, class U>
    constexpr const T& get(const pair<T, U>& p) noexcept;
  template <class T, class U>
    constexpr T&& get(pair<T, U>&& p) noexcept;
  template <class T, class U>
    constexpr T& get(pair<U, T>& p) noexcept;
  template <class T, class U>
    constexpr const T& get(const pair<U, T>& p) noexcept;
  template <class T, class U>
    constexpr T&& get(pair<U, T>&& p) noexcept;

  // 20.33.2, pair piecewise construction
  struct piecewise_construct_t { };
  constexpr piecewise_construct_t piecewise_construct{};
  template <class... Types> class tuple;  // defined in <tuple>

  // 20.66, Compile-time integer sequences
  template<class T, T...> struct integer_sequence;
  template<size_t... I>
    using index_sequence = integer_sequence<size_t, I...>;

  template<class T, T N>
    using make_integer_sequence = integer_sequence<T, see below>;
  template<size_t N>
    using make_index_sequence = make_integer_sequence<size_t, N>;

  template<class... T>
    using index_sequence_for = make_index_sequence<sizeof...(T)>;
}
```

20.3.1 Operators [operators]

1 To avoid redundant definitions of `operator!=` out of `operator==` and operators `>`, `<=`, and `>=` out of `operator<`, the library provides the following:

```
template <class T> bool operator!=(const T& x, const T& y);
```

2 *Requires:* Type `T` is `EqualityComparable` (Table 17).

3 *Returns:* `!(x == y)`.

```
template <class T> bool operator>(const T& x, const T& y);
```

4 *Requires:* Type `T` is `LessThanComparable` (Table 18).

5 *Returns:* `y < x`.

```
template <class T> bool operator<=(const T& x, const T& y);
```

6 *Requires:* Type `T` is `LessThanComparable` (Table 18).

7 *Returns:* `!(y < x)`.

```
template <class T> bool operator>=(const T& x, const T& y);
```

8 *Requires:* Type `T` is `LessThanComparable` (Table 18).

9 *Returns:* `!(x < y)`.

10 In this library, whenever a declaration is provided for an `operator!=`, `operator>`, `operator>=`, or `operator<=`, and requirements and semantics are not explicitly provided, the requirements and semantics are as specified in this Clause.

20.3.2 swap [utility.swap]

```
template<class T> void swap(T& a, T& b) noexcept(see below);
```

1

Remark: The expression inside `noexcept` is equivalent to:

```
is_nothrow_move_constructible<T>::value &&
is_nothrow_move_assignable<T>::value
```

1 *Requires:* Type `T` shall be `MoveConstructible` (Table 20) and `MoveAssignable` (Table 22).

2 *Effects:* Exchanges values stored in two locations.

```
template<class T, size_t N>
  void swap(T (&a)[N], T (&b)[N]) noexcept(noexcept(swap(*a, *b)));
```

3 *Requires:* `a[i]` shall be swappable with (17.143.0.1) `b[i]` for all `i` in the range `[0,N)`.

4 *Effects:* `swap_ranges(a, a + N, b)`

20.4.1 exchange [utility.exchange]

```
template <class T, class U=T> T exchange(T& obj, U&& new_val);
```

1 *Effects:* Equivalent to:

```
T old_val = std::move(obj);
obj = std::forward<U>(new_val);
return old_val;
```

20.4.2 forward/move helpers [forward]

1

The library provides templated helper functions to simplify applying move semantics to an lvalue and to simplify the implementation of forwarding functions.

```
template <class T> constexpr T&& forward(remove_reference_t<T>& t) noexcept;
template <class T> constexpr T&& forward(remove_reference_t<T>&& t) noexcept;
```

1 *Returns:* `static_cast<T&&>(t)`.

2

Remark: If the second form is instantiated with an lvalue reference type, the program is ill-formed.

1 [*Example:*

```
template <class T, class A1, class A2>
shared_ptr<T> factory(A1&& a1, A2&& a2) {
  return shared_ptr<T>(new T(std::forward<A1>(a1), std::forward<A2>(a2)));
}
```

```
struct A {
  A(int&, const double&);
};

void g() {
  shared_ptr<A> sp1 = factory<A>(2, 1.414); // error: 2 will not bind to int&
  int i = 2;
  shared_ptr<A> sp2 = factory<A>(i, 1.414); // OK
}
```

2

In the first call to `factory`, `A1` is deduced as `int`, so 2 is forwarded to `A`'s constructor as an rvalue. In the second call to `factory`, `A1` is deduced as `int&`, so `i` is forwarded to `A`'s constructor as an lvalue. In both cases, `A2` is deduced as `double`, so 1.414 is forwarded to `A`'s constructor as an rvalue.

— *end example*]

```
template <class T> constexpr remove_reference_t<T>&& move(T&& t) noexcept;
```

1 *Returns:* `static_cast<remove_reference_t<T>&&>(t)`.

2 [*Example:*

```
template <class T, class A1>
shared_ptr<T> factory(A1&& a1) {
  return shared_ptr<T>(new T(std::forward<A1>(a1)));
}

struct A {
  A();
  A(const A&);   // copies from lvalues
  A(A&&);        // moves from rvalues
};

void g() {
  A a;
  shared_ptr<A> sp1 = factory<A>(a);              // "a" binds to A(const A&)
  shared_ptr<A> sp1 = factory<A>(std::move(a));   // "a" binds to A(A&&)
}
```

3 In the first call to `factory`, `A1` is deduced as `A&`, so `a` is forwarded as a non-const lvalue. This binds to the constructor `A(const A&)`, which copies the value from `a`. In the second call to `factory`, because of the call `std::move(a)`, `A1` is deduced as `A`, so `a` is forwarded as an rvalue. This binds to the constructor `A(A&&)`, which moves the value from `a`.

— *end example*]

```
template <class T> constexpr conditional_t<
  !is_nothrow_move_constructible<T>::value && is_copy_constructible<T>::value,
  const T&, T&&> move_if_noexcept(T& x) noexcept;
```

4 *Returns:* `std::move(x)`

20.11.1 Function template `declval` [declval]

1

The library provides the function template `declval` to simplify the definition of expressions which occur as unevaluated operands (Clause 5).

```
template <class T>
  add_rvalue_reference_t<T> declval() noexcept;  // as unevaluated operand
```

1 *Remarks:* If this function is odr-used (3.91), the program is ill-formed.

2 *Remarks:* The template parameter `T` of `declval` may be an incomplete type.

[*Example:*

```
template <class To, class From>
  decltype(static_cast<To>(declval<From>())) convert(From&&);
```

declares a function template `convert` which only participates in overloading if the type `From` can be explicitly converted to type `To`. For another example see class template `common_type` (20.570.1.6). — *end example*]

20.15 Pairs [pairs]

20.15.1 In general [pairs.general]

1 The library provides a template for heterogeneous pairs of values. The library also provides a matching function template to simplify their construction and several templates that provide access to `pair` objects as if they were `tuple` objects (see 20.56.0.1 and 20.57.0.1).

20.15.2 Class template `pair` [pairs.pair]

```
// defined in header <utility>

namespace std {
  template <class T1, class T2>
  struct pair {
    typedef T1 first_type;
    typedef T2 second_type;

    T1 first;
    T2 second;
    pair(const pair&) = default;
    pair(pair&&) = default;
    constexpr pair();
    constexpr pair(const T1& x, const T2& y);
    template<class U, class V> constexpr pair(U&& x, V&& y);
    template<class U, class V> constexpr pair(const pair<U, V>& p);
    template<class U, class V> constexpr pair(pair<U, V>&& p);
    template <class... Args1, class... Args2>
      pair(piecewise_construct_t,
           tuple<Args1...> first_args, tuple<Args2...> second_args);

    pair& operator=(const pair& p);
    template<class U, class V> pair& operator=(const pair<U, V>& p);
    pair& operator=(pair&& p) noexcept(see below);
    template<class U, class V> pair& operator=(pair<U, V>&& p);

    void swap(pair& p) noexcept(see below);
  };
}
```

1 Constructors and member functions of `pair` shall not throw exceptions unless one of the element-wise operations specified to be called for that operation throws an exception.

2

The defaulted move and copy constructor, respectively, of pair shall be a `constexpr` function if and only if all required element-wise initializations for copy and move, respectively, would satisfy the requirements for a `constexpr` function.

```
constexpr pair();
```

1 *Requires:* `is_default_constructible<first_type>::value` is `true` and `is_default_constructible<second_type>::value` is `true`.

2 *Effects:* Value-initializes `first` and `second`.

```
constexpr pair(const T1& x, const T2& y);
```

3 *Requires:* `is_copy_constructible<first_type>::value` is `true` and `is_copy_constructible<second_type>::value` is `true`.

4

Effects: The constructor initializes `first` with `x` and `second` with `y`.

```
template<class U, class V> constexpr pair(U&& x, V&& y);
```

1

Requires: `is_constructible<first_type, U&&>::value` is `true` and `is_constructible<second_type, V&&>::value` is `true`.

1

Effects: The constructor initializes `first` with `std::forward<U>(x)` and `second` with `std::forward<V>(y)`.

1

Remarks: If `U` is not implicitly convertible to `first_type` or `V` is not implicitly convertible to `second_type` this constructor shall not participate in overload resolution.

```
template<class U, class V> constexpr pair(const pair<U, V>& p);
```

1 *Requires:* `is_constructible<first_type, const U&>::value` is `true` and `is_constructible<second_type, const V&>::value` is `true`.

2 *Effects:* Initializes members from the corresponding members of the argument.

3

Remark: This constructor shall not participate in overload resolution unless `const U&` is implicitly convertible to `first_type` and `const V&` is implicitly convertible to `second_type`.

```
template<class U, class V> constexpr pair(pair<U, V>&& p);
```

1 *Requires:* `is_constructible<first_type, U&&>::value` is `true` and `is_constructible<second_type, V&&>::value` is `true`.

2 *Effects:* The constructor initializes `first` with `std::forward<U>(p.first)` and `second` with `std::forward<V>(p.second)`.

3 *Remark:* This constructor shall not participate in overload resolution unless `U` is implicitly convertible to `first_type` and `V` is implicitly convertible to `second_type`.

```
template<class... Args1, class... Args2>
  pair(piecewise_construct_t,
       tuple<Args1...> first_args, tuple<Args2...> second_args);
```

4 *Requires:* `is_constructible<first_type, Args1&&...>::value` is `true` and `is_constructible<second_type, Args2&&...>::value` is `true`.

5 *Effects:* The constructor initializes `first` with arguments of types `Args1...` obtained by forwarding the elements of `first_args` and initializes `second` with arguments of types `Args2...` obtained by forwarding the elements of `second_args`. (Here, forwarding an element `x` of type `U` within a `tuple` object means calling `std::forward<U>(x)`.) This form of construction, whereby constructor arguments for `first` and `second` are each provided in a separate `tuple` object, is called *piecewise construction*.

```
pair& operator=(const pair& p);
```

6 *Requires:* `is_copy_assignable<first_type>::value` is `true` and `is_copy_assignable<second_type>::value` is `true`.

7 *Effects:* Assigns `p.first` to `first` and `p.second` to `second`.

8 *Returns:* `*this`.

```
template<class U, class V> pair& operator=(const pair<U, V>& p);
```

9

Requires: `is_assignable<first_type&, const U&>::value` is `true` and `is_assignable<second_type&, const V&>::value` is `true`.

1 *Effects:* Assigns `p.first` to `first` and `p.second` to `second`.

2 *Returns:* `*this`.

```
pair& operator=(pair&& p) noexcept(see below);
```

3 *Remarks:* The expression inside `noexcept` is equivalent to:

```
is_nothrow_move_assignable<T1>::value &&
is_nothrow_move_assignable<T2>::value
```

4 *Requires:* `is_move_assignable<first_type>::value` is `true` and `is_move_assignable<second_type>::value` is `true`.

5 *Effects:* Assigns to `first` with `std::forward<first_type>(p.first)` and to `second` with `std::forward<second_type>(p.second)`.

6 *Returns:* `*this`.

```
template<class U, class V> pair& operator=(pair<U, V>&& p);
```

7 *Requires:* `is_assignable<first_type&, U&&>::value` is `true` and `is_assignable<second_type&, V&&>::value` is `true`.

8 *Effects:* Assigns to `first` with `std::forward<U>(p.first)` and to `second` with `std::forward<V>(p.second)`.

9 *Returns:* `*this`.

```
void swap(pair& p) noexcept(see below);
```

10 *Remarks:* The expression inside `noexcept` is equivalent to:

```
noexcept(swap(first, p.first)) &&
noexcept(swap(second, p.second))
```

11 *Requires:* `first` shall be swappable with (17.143.0.1) `p.first` and `second` shall be swappable with `p.second`.

12 *Effects:* Swaps `first` with `p.first` and `second` with `p.second`.

20.28.1 Specialized algorithms [pairs.spec]

```
template <class T1, class T2>
  constexpr bool operator==(const pair<T1, T2>& x, const pair<T1, T2>& y);
```

1 *Returns:* `x.first == y.first && x.second == y.second`.

```
template <class T1, class T2>
  constexpr bool operator<(const pair<T1, T2>& x, const pair<T1, T2>& y);
```

2 *Returns:* `x.first < y.first || (!(y.first < x.first) && x.second < y.second)`.

```
template <class T1, class T2>
  constexpr bool operator!=(const pair<T1, T2>& x, const pair<T1, T2>& y);
```

1 *Returns:* `!(x == y)`

```
template <class T1, class T2>
  constexpr bool operator>(const pair<T1, T2>& x, const pair<T1, T2>& y);
```

2 *Returns:* `y < x`

```
template <class T1, class T2>
  constexpr bool operator>=(const pair<T1, T2>& x, const pair<T1, T2>& y);
```

3 *Returns:* `!(x < y)`

```
template <class T1, class T2>
  constexpr bool operator<=(const pair<T1, T2>& x, const pair<T1, T2>& y);
```

4 *Returns:* `!(y < x)`

```
template<class T1, class T2> void swap(pair<T1, T2>& x, pair<T1, T2>& y)
  noexcept(noexcept(x.swap(y)));
```

5 *Effects:* `x.swap(y)`

```
template <class T1, class T2>
  constexpr pair<V1, V2> make_pair(T1&& x, T2&& y);
```

1 *Returns:* `pair<V1, V2>(std::forward<T1>(x), std::forward<T2>(y))`;

where `V1` and `V2` are determined as follows: Let `Ui` be `decay_t<Ti>` for each `Ti`. Then each `Vi` is `X&` if `Ui` equals `reference_wrapper<X>`, otherwise `Vi` is `Ui`.

1 [*Example:* In place of:

```
return pair<int, double>(5, 3.1415926);    // explicit types
```

a C++ program may contain:

```
return make_pair(5, 3.1415926);            // types are deduced
```

— *end example*]

20.33.1 Tuple-like access to pair [pair.astuple]

```
template <class T1, class T2>
struct tuple_size<pair<T1, T2>>
  : integral_constant<size_t, 2> { };
```

```
tuple_element<0, pair<T1, T2> >::type
```

1 *Value:* the type `T1`.

```
tuple_element<1, pair<T1, T2> >::type
```

2 *Value:* the type T2.

```
template<size_t I, class T1, class T2>
  constexpr tuple_element_t<I, pair<T1, T2>>&
    get(pair<T1, T2>& p) noexcept;
template<size_t I, class T1, class T2>
  constexpr const tuple_element_t<I, pair<T1, T2>>&
    get(const pair<T1, T2>& p) noexcept;
```

3 *Returns:* If `I == 0` returns `p.first`; if `I == 1` returns `p.second`; otherwise the program is ill-formed.

```
template<size_t I, class T1, class T2>
  constexpr tuple_element_t<I, pair<T1, T2>>&&
    get(pair<T1, T2>&& p) noexcept;
```

4 *Returns:* If `I == 0` returns `std::forward<T1&&>(p.first)`; if `I == 1` returns `std::forward<T2&&>(p.second)`; otherwise the program is ill-formed.

```
template <class T, class U>
  constexpr T& get(pair<T, U>& p) noexcept;
template <class T, class U>
  constexpr const T& get(const pair<T, U>& p) noexcept;
```

5 *Requires:* `T` and `U` are distinct types. Otherwise, the program is ill-formed.

6 *Returns:* `get<0>(p);`

```
template <class T, class U>
  constexpr T&& get(pair<T, U>&& p) noexcept;
```

7 *Requires:* `T` and `U` are distinct types. Otherwise, the program is ill-formed.

8 *Returns:* `get<0>(std::move(p));`

```
template <class T, class U>
  constexpr T& get(pair<U, T>& p) noexcept;
template <class T, class U>
  constexpr const T& get(const pair<U, T>& p) noexcept;
```

9 *Requires:* `T` and `U` are distinct types. Otherwise, the program is ill-formed.

10 *Returns:* `get<1>(p);`

```
template <class T, class U>
  constexpr T&& get(pair<U, T>&& p) noexcept;
```

11 *Requires:* `T` and `U` are distinct types. Otherwise, the program is ill-formed.

12 *Returns:* `get<1>(std::move(p));`

20.33.2 Piecewise construction [pair.piecewise]

```
struct piecewise_construct_t { };
constexpr piecewise_construct_t piecewise_construct{};
```

1 The `struct piecewise_construct_t` is an empty structure type used as a unique type to disambiguate constructor and function overloading. Specifically, `pair` has a constructor with `piecewise_construct_t` as the first argument, immediately followed by two `tuple` (20.34) arguments used for piecewise construction of the elements of the `pair` object.

20.34 Tuples [tuple]

20.34.1 In general [tuple.general]

1

This subclause describes the tuple library that provides a tuple type as the class template `tuple` that can be instantiated with any number of arguments. Each template argument specifies the type of an element in the `tuple`. Consequently, tuples are heterogeneous, fixed-size collections of values. An instantiation of `tuple` with two arguments is similar to an instantiation of `pair` with the same two arguments. See 20.15.

1 **Header `<tuple>` synopsis**

```
namespace std {
  // 20.37.1, class template tuple:
  template <class... Types> class tuple;

  // 20.53.0.2, tuple creation functions:
  const unspecified  ignore;

  template <class... Types>
    constexpr tuple<VTypes...> make_tuple(Types&&...);
  template <class... Types>
    constexpr tuple<Types&&...> forward_as_tuple(Types&&...) noexcept;

  template<class... Types>
    constexpr tuple<Types&...> tie(Types&...) noexcept;

  template <class... Tuples>
    constexpr tuple<Ctypes...> tuple_cat(Tuples&&...);

  // 20.56.0.1, tuple helper classes:
  template <class T> class tuple_size;  // undefined
  template <class T> class tuple_size<const T>;
  template <class T> class tuple_size<volatile T>;
  template <class T> class tuple_size<const volatile T>;

  template <class... Types> class tuple_size<tuple<Types...> >;

  template <size_t I, class T> class tuple_element;    // undefined

  // 20.65.0.1, specialized algorithms:
  template <class... Types>
    void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below);
}
```

20.37.1 Class template tuple [tuple.tuple]

```
namespace std {
  template <class... Types>
  class tuple  {
  public:

    // 20.37.1.1, tuple construction
    constexpr tuple();
    constexpr explicit tuple(const Types&...);
    template <class... UTypes>
      constexpr explicit tuple(UTypes&&...);

    tuple(const tuple&) = default;
    tuple(tuple&&) = default;
```

```
    template <class... UTypes>
      constexpr tuple(const tuple<UTypes...>&);
    template <class... UTypes>
      constexpr tuple(tuple<UTypes...>&&);

    template <class U1, class U2>
      constexpr tuple(const pair<U1, U2>&);       // only if sizeof...(Types) == 2
    template <class U1, class U2>
      constexpr tuple(pair<U1, U2>&&);            // only if sizeof...(Types) == 2

    // allocator-extended constructors
    template <class Alloc>
      tuple(allocator_arg_t, const Alloc& a);
    template <class Alloc>
      tuple(allocator_arg_t, const Alloc& a, const Types&...);
    template <class Alloc, class... UTypes>
      tuple(allocator_arg_t, const Alloc& a, UTypes&&...);
    template <class Alloc>
      tuple(allocator_arg_t, const Alloc& a, const tuple&);
    template <class Alloc>
      tuple(allocator_arg_t, const Alloc& a, tuple&&);
    template <class Alloc, class... UTypes>
      tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&);
    template <class Alloc, class... UTypes>
      tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&&);
    template <class Alloc, class U1, class U2>
      tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&);
    template <class Alloc, class U1, class U2>
      tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&&);

    // 20.51.0.1, tuple assignment
    tuple& operator=(const tuple&);
    tuple& operator=(tuple&&) noexcept(see below);

    template <class... UTypes>
      tuple& operator=(const tuple<UTypes...>&);
    template <class... UTypes>
      tuple& operator=(tuple<UTypes...>&&);

    template <class U1, class U2>
      tuple& operator=(const pair<U1, U2>&);     // only if sizeof...(Types) == 2
    template <class U1, class U2>
      tuple& operator=(pair<U1, U2>&&);          // only if sizeof...(Types) == 2

    // 20.53.0.1, tuple swap
    void swap(tuple&) noexcept(see below);
  };
}
```

20.37.1.1 Construction [tuple.cnstr]

1 For each `tuple` constructor, an exception is thrown only if the construction of one of the types in `Types` throws an exception.

2

The defaulted move and copy constructor, respectively, of `tuple` shall be a `constexpr` function if and only if all required element-wise initializations for copy and move, respectively, would satisfy the requirements for a `constexpr` function. The defaulted move and copy constructor of `tuple<>` shall be `constexpr` functions.

1 In the constructor descriptions that follow, let i be in the range `[0,sizeof...(Types))` in order, T_i be the ith type in `Types`, and U_i be the ith type in a template parameter pack named `UTypes`, where indexing is zero-based.

```
constexpr tuple();
```

2 *Requires:* `is_default_constructible<`T_i`>::value` is true for all i.

3 *Effects:* Value initializes each element.

```
constexpr explicit tuple(const Types&...);
```

4 *Requires:* `is_copy_constructible<`T_i`>::value` is true for all i.

5 *Effects:* Initializes each element with the value of the corresponding parameter.

```
template <class... UTypes>
  constexpr explicit tuple(UTypes&&... u);
```

1 *Requires:* `sizeof...(Types) == sizeof...(UTypes)`. `is_constructible<`T_i`, `U_i`&&>::value` is `true` for all i.

1 *Effects:* Initializes the elements in the tuple with the corresponding value in `std::forward<UTypes>(u)`.

2 *Remark:* This constructor shall not participate in overload resolution unless each type in `UTypes` is implicitly convertible to its corresponding type in `Types`.

```
tuple(const tuple& u) = default;
```

1 *Requires:* `is_copy_constructible<`T_i`>::value` is `true` for all i.

2 *Effects:* Initializes each element of `*this` with the corresponding element of `u`.

```
tuple(tuple&& u) = default;
```

3 *Requires:* `is_move_constructible<`T_i`>::value` is `true` for all i.

4 *Effects:* For all i, initializes the ith element of `*this` with `std::forward<`T_i`>(get<`i`>(u))`.

```
template <class... UTypes> constexpr tuple(const tuple<UTypes...>& u);
```

1 *Requires:* `sizeof...(Types) == sizeof...(UTypes)`. `is_constructible<`T_i`, const `U_i`&>::value` is `true` for all i.

1 *Effects:* Constructs each element of `*this` with the corresponding element of `u`.

1 *Remark:* This constructor shall not participate in overload resolution unless `const` U_i`&` is implicitly convertible to T_i for all i.

```
template <class... UTypes> constexpr tuple(tuple<UTypes...>&& u);
```

1 *Requires:* `sizeof...(Types) == sizeof...(UTypes)`. `is_constructible<`T_i`, `U_i`&&>::value` is `true` for all i.

2 *Effects:* For all i, initializes the ith element of `*this` with `std::forward<`U_i`>(get<`i`>(u))`.

3 *Remark:* This constructor shall not participate in overload resolution unless each type in `UTypes` is implicitly convertible to its corresponding type in `Types`.

```
template <class U1, class U2> constexpr tuple(const pair<U1, U2>& u);
```

4 *Requires:* `sizeof...(Types) == 2`. `is_constructible<`T_0`, const U1&>::value` is `true` for the first type T_0 in `Types` and `is_constructible<`T_1`, const U2&>::value` is `true` for the second type T_1 in `Types`.

5 *Effects:* Constructs the first element with `u.first` and the second element with `u.second`.

6 *Remark:* This constructor shall not participate in overload resolution unless `const U1&` is implicitly convertible to T_0 and `const U2&` is implicitly convertible to T_1.

```
template <class U1, class U2> constexpr tuple(pair<U1, U2>&& u);
```

7 *Requires:* `sizeof...(Types) == 2`. `is_constructible<`T_0`, U1&&>::value` is `true` for the first type T_0 in `Types` and `is_constructible<`T_1`, U2&&>::value` is `true` for the second type T_1 in `Types`.

8 *Effects:* Initializes the first element with `std::forward<U1>(u.first)` and the second element with `std::forward<U2>(u.second)`.

9 *Remark:* This constructor shall not participate in overload resolution unless `U1` is implicitly convertible to T_0 and `U2` is implicitly convertible to T_1.

```
template <class Alloc>
  tuple(allocator_arg_t, const Alloc& a);
template <class Alloc>
  tuple(allocator_arg_t, const Alloc& a, const Types&...);
template <class Alloc, class... UTypes>
  tuple(allocator_arg_t, const Alloc& a, UTypes&&...);
template <class Alloc>
  tuple(allocator_arg_t, const Alloc& a, const tuple&);
template <class Alloc>
  tuple(allocator_arg_t, const Alloc& a, tuple&&);
template <class Alloc, class... UTypes>
  tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&);
template <class Alloc, class... UTypes>
  tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&&);
template <class Alloc, class U1, class U2>
  tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&);
template <class Alloc, class U1, class U2>
  tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&&);
```

10 *Requires:* `Alloc` shall meet the requirements for an `Allocator` (17.165.0.1).

11 *Effects:* Equivalent to the preceding constructors except that each element is constructed with uses-allocator construction (20.86.2.2).

20.51.0.1 Assignment [tuple.assign]

1 For each `tuple` assignment operator, an exception is thrown only if the assignment of one of the types in `Types` throws an exception. In the function descriptions that follow, let i be in the range `[0,sizeof...(Types))` in order, T_i be the ith type in `Types`, and U_i be the ith type in a template parameter pack named `UTypes`, where indexing is zero-based.

```
tuple& operator=(const tuple& u);
```

2 *Requires:* `is_copy_assignable<`T_i`>::value` is `true` for all i.

3 *Effects:* Assigns each element of `u` to the corresponding element of `*this`.

1 *Returns:* `*this`

```
tuple& operator=(tuple&& u) noexcept(see below);
```

2 *Remark:* The expression inside `noexcept` is equivalent to the logical AND of the following expressions:

```
is_nothrow_move_assignable<Ti>::value
```

where T_i is the ith type in `Types`.

3 *Requires:* `is_move_assignable<`T_i`>::value` is `true` for all i.

4 *Effects:* For all i, assigns `std::forward<`T_i`>(get<`i`>(u))` to `get<`i`>(*this)`.

5 *Returns:* `*this`.

```
template <class... UTypes>
  tuple& operator=(const tuple<UTypes...>& u);
```

1 *Requires:* `sizeof...(Types) == sizeof...(UTypes)` and `is_assignable<`T_i`&, const `U_i`&>::value` is `true` for all i.

2 *Effects:* Assigns each element of `u` to the corresponding element of `*this`.

3 *Returns:* `*this`

```
template <class... UTypes>
  tuple& operator=(tuple<UTypes...>&& u);
```

4 *Requires:* `is_assignable<Ti&, Ui&&>::value == true` for all `i`. `sizeof...(Types) == sizeof...(UTypes)`.

5 *Effects:* For all i, assigns `std::forward<`U_i`>(get<`i`>(u))` to `get<`i`>(*this)`.

6 *Returns:* `*this`.

```
template <class U1, class U2> tuple& operator=(const pair<U1, U2>& u);
```

7 *Requires:* `sizeof...(Types) == 2`. `is_assignable<`T_0`&, const U1&>::value` is `true` for the first type T_0 in `Types` and `is_assignable<`T_1`&, const U2&>::value` is `true` for the second type T_1 in `Types`.

8 *Effects:* Assigns `u.first` to the first element of `*this` and `u.second` to the second element of `*this`.

9 *Returns:* `*this`

```
template <class U1, class U2> tuple& operator=(pair<U1, U2>&& u);
```

10 *Requires:* `sizeof...(Types) == 2`. `is_assignable<`T_0`&, U1&&>::value` is `true` for the first type T_0 in `Types` and `is_assignable<`T_1`&, U2&&>::value` is `true` for the second type T_1 in `Types`.

11 *Effects:* Assigns `std::forward<U1>(u.first)` to the first element of `*this` and `std::forward<U2>(u.second)` to the second element of `*this`.

12 *Returns:* `*this`.

20.53.0.1 `swap` [tuple.swap]

```
void swap(tuple& rhs) noexcept(see below);
```

1 *Remark:* The expression inside `noexcept` is equivalent to the logical AND of the following expressions:

```
noexcept(swap(declval<Ti&>>(), declval<Ti&>()))
```

where T_i is the ith type in `Types`.

2 *Requires:* Each element in `*this` shall be swappable with (17.143.0.1) the corresponding element in `rhs`.

3 *Effects:* Calls `swap` for each element in `*this` and its corresponding element in `rhs`.

4 *Throws:* Nothing unless one of the element-wise `swap` calls throws an exception.

20.53.0.2 Tuple creation functions [tuple.creation]

1 In the function descriptions that follow, let i be in the range `[0,sizeof...(TTypes))` in order and let T_i be the ith type in a template parameter pack named `TTypes`; let j be in the range `[0,sizeof...(UTypes))` in order and U_j be the jth type in a template parameter pack named `UTypes`, where indexing is zero-based.

```
template<class... Types>
  constexpr tuple<VTypes...> make_tuple(Types&&... t);
```

2 Let U_i be `decay_t<`T_i`>` for each T_i in `Types`. Then each V_i in `VTypes` is `X&` if U_i equals `reference_wrapper<X>`, otherwise V_i is U_i.

1 *Returns:* `tuple<VTypes...>(std::forward<Types>(t)...)`.

2 [*Example:*

```
int i; float j;
make_tuple(1, ref(i), cref(j))
```

creates a tuple of type

```
tuple<int, int&, const float&>
```

— *end example*]

```
template<class... Types>
  constexpr tuple<Types&&...> forward_as_tuple(Types&&... t) noexcept;
```

3 *Effects:* Constructs a tuple of references to the arguments in `t` suitable for forwarding as arguments to a function. Because the result may contain references to temporary variables, a program shall ensure that the return value of this function does not outlive any of its arguments. (e.g., the program should typically not store the result in a named variable).

4 *Returns:* `tuple<Types&&...>(std::forward<Types>(t)...)`

```
template<class... Types>
  constexpr tuple<Types&...> tie(Types&... t) noexcept;
```

5

Returns: `tuple<Types&...>(t...)`. When an argument in `t` is `ignore`, assigning any value to the corresponding tuple element has no effect.

1 [*Example:* `tie` functions allow one to create tuples that unpack tuples into variables. `ignore` can be used for elements that are not needed:

```
int i; std::string s;
tie(i, ignore, s) = make_tuple(42, 3.14, "C++");
// i == 42, s == "C++"
```

— *end example*]

```
template <class... Tuples>
  constexpr tuple<CTypes...> tuple_cat(Tuples&&... tpls);
```

2 In the following paragraphs, let T_i be the ith type in `Tuples`, U_i be `remove_reference_t<Ti>`, and tp_i be the ith parameter in the function parameter pack `tpls`, where all indexing is zero-based.

3 *Requires:* For all i, U_i shall be the type cv_i `tuple<`$Args_i$`...>`, where cv_i is the (possibly empty) i^{th} cv-qualifier-seq and $Args_i$ is the parameter pack representing the element types in U_i. Let A_{ik} be the ${k_i}^{th}$ type in $Args_i$. For all A_{ik} the following requirements shall be satisfied: If T_i is deduced as an lvalue reference type, then `is_constructible<`A_{ik}`,` cv_i A_{ik}`&>::value == true`, otherwise `is_constructible<`A_{ik}`,` $cv_i A_{ik}$`&&>::value == true`.

4 *Remarks:* The types in `CTypes` shall be equal to the ordered sequence of the extended types $Args_0$`...`, $Args_1$`...`, ... $Args_{n-1}$`...`, where n is equal to `sizeof...(Tuples)`. Let e_i`...` be the ith ordered sequence of tuple elements of the resulting `tuple` object corresponding to the type sequence $Args_i$.

5 *Returns:* A `tuple` object constructed by initializing the ${k_i}^{th}$ type element e_{ik} in e_i`...` with `get<`k_i`>(std::forward<`T_i`>(`tp_i`))` for each valid k_i and each group e_i in order.

6 *Note:* An implementation may support additional types in the parameter pack `Tuples` that support the `tuple`-like protocol, such as `pair` and `array`.

20.56.0.1 Tuple helper classes [tuple.helper]

```
template <class T> struct tuple_size;
```

Remarks: All specializations of `tuple_size<T>` shall meet the `UnaryTypeTrait` requirements (20.450.1) with a `BaseCharacteristic` of `integral_constant<size_t, N>` for some `N`.

```
template <class... Types>
class tuple_size<tuple<Types...> >
  : public integral_constant<size_t, sizeof...(Types)> { };

template <size_t I, class... Types>
class tuple_element<I, tuple<Types...> > {
public:
  typedef TI type;
};
```

1 *Requires:* `I < sizeof...(Types)`. The program is ill-formed if `I` is out of bounds.

2 *Type:* `TI` is the type of the `I`th element of `Types`, where indexing is zero-based.

```
template <class T> class tuple_size<const T>;
template <class T> class tuple_size<volatile T>;
template <class T> class tuple_size<const volatile T>;
```

3

Let *TS* denote `tuple_size<T>` of the *cv*-unqualified type `T`. Then each of the three templates shall meet the `UnaryTypeTrait` requirements (20.450.1) with a `BaseCharacteristic` of

```
integral_constant<size_t, TS::value>
```

```
template <size_t I, class T> class tuple_element<I, const T>;
template <size_t I, class T> class tuple_element<I, volatile T>;
template <size_t I, class T> class tuple_element<I, const volatile T>;
```

Let *TE* denote `tuple_element<I, T>` of the *cv*-unqualified type `T`. Then each of the three templates shall meet the `TransformationTrait` requirements (20.450.1) with a member typedef `type` that names the following type:

— for the first specialization, `add_const_t<`*TE*`::type>`,

— for the second specialization, `add_volatile_t<`*TE*`::type>`, and

— for the third specialization, `add_cv_t<`*TE*`::type>`.

20.57.0.1 Element access [tuple.elem]

```
template <size_t I, class... Types>
  constexpr tuple_element_t<I, tuple<Types...> >& get(tuple<Types...>& t) noexcept;
```

1 *Requires:* `I < sizeof...(Types)`. The program is ill-formed if `I` is out of bounds.

2 *Returns:* A reference to the `I`th element of `t`, where indexing is zero-based.

```
template <size_t I, class... Types>
  constexpr tuple_element_t<I, tuple<Types...> >&& get(tuple<Types...>&& t) noexcept;
```

3 *Effects:* Equivalent to `return std::forward<typename tuple_element<I, tuple<Types...> > ::type&&>(get<I>(t));`

4 *Note:* if a `T` in `Types` is some reference type `X&`, the return type is `X&`, not `X&&`. However, if the element type is a non-reference type `T`, the return type is `T&&`.

```
template <size_t I, class... Types>
  constexpr tuple_element_t<I, tuple<Types...> > const& get(const tuple<Types...>& t) noexcept;
```

5 *Requires:* `I < sizeof...(Types)`. The program is ill-formed if `I` is out of bounds.

6 *Returns:* A const reference to the `I`th element of `t`, where indexing is zero-based.

7 [*Note:* Constness is shallow. If a `T` in `Types` is some reference type `X&`, the return type is `X&`, not `const X&`. However, if the element type is non-reference type `T`, the return type is `const T&`. This is consistent with how constness is defined to work for member variables of reference type. — *end note*]

```
template <class T, class... Types>
  constexpr T& get(tuple<Types...>& t) noexcept;
template <class T, class... Types>
  constexpr T&& get(tuple<Types...>&& t) noexcept;
template <class T, class... Types>
  constexpr const T& get(const tuple<Types...>& t) noexcept;
```

8

Requires: The type `T` occurs exactly once in `Types...`. Otherwise, the program is ill-formed.

1 *Returns:* A reference to the element of `t` corresponding to the type `T` in `Types...`.

2 [*Example:*

```
const tuple<int, const int, double, double> t(1, 2, 3.4, 5.6);
const int &i1 = get<int>(t);        // OK. Not ambiguous. i1 == 1
const int &i2 = get<const int>(t);  // OK. Not ambiguous. i2 == 2
const double &d = get<double>(t);   // ERROR. ill-formed
```

— *end example*]

3

[*Note:* The reason `get` is a nonmember function is that if this functionality had been provided as a member function, code where the type depended on a template parameter would have required using the `template` keyword. — *end note*]

20.61.0.1 Relational operators [tuple.rel]

```
template<class... TTypes, class... UTypes>
  constexpr bool operator==(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

1

Requires: For all `i`, where `0 <= i` and `i < sizeof...(TTypes)`, `get<i>(t) == get<i>(u)` is a valid expression returning a type that is convertible to `bool`. `sizeof...(TTypes) == sizeof...(UTypes)`.

1 *Returns:* `true` if `get<i>(t) == get<i>(u)` for all `i`, otherwise `false`. For any two zero-length tuples `e` and `f`, `e == f` returns `true`.

2 *Effects:* The elementary comparisons are performed in order from the zeroth index upwards. No comparisons or element accesses are performed after the first equality comparison that evaluates to `false`.

```
template<class... TTypes, class... UTypes>
  constexpr bool operator<(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

3 *Requires:* For all `i`, where `0 <= i` and `i < sizeof...(TTypes)`, `get<i>(t) < get<i>(u)` and `get<i>(u) < get<i>(t)` are valid expressions returning types that are convertible to `bool`. `sizeof...(TTypes) == sizeof...(UTypes)`.

4 *Returns:* The result of a lexicographical comparison between `t` and `u`. The result is defined as: `(bool)(get<0>(t) < get<0>(u)) || (!(bool)(get<0>(u) < get<0>(t)) && t`$_{\text{tail}}$ `<` `u`$_{\text{tail}}$`)`, where `r`$_{\text{tail}}$ for some tuple `r` is a tuple containing all but the first element of `r`. For any two zero-length tuples `e` and `f`, `e < f` returns `false`.

```
template<class... TTypes, class... UTypes>
  constexpr bool operator!=(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

1 *Returns:* `!(t == u)`.

```
template<class... TTypes, class... UTypes>
  constexpr bool operator>(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

2 *Returns:* `u < t`.

```
template<class... TTypes, class... UTypes>
  constexpr bool operator<=(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

3 *Returns:* `!(u < t)`

```
template<class... TTypes, class... UTypes>
  constexpr bool operator>=(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

4 *Returns:* `!(t < u)`

5 [*Note:* The above definitions for comparison operators do not require $\texttt{t}_{\text{tail}}$ (or $\texttt{u}_{\text{tail}}$) to be constructed. It may not even be possible, as `t` and `u` are not required to be copy constructible. Also, all comparison operators are short circuited; they do not perform element accesses beyond what is required to determine the result of the comparison. — *end note*]

20.64.0.1 Tuple traits [tuple.traits]

```
template <class... Types, class Alloc>
  struct uses_allocator<tuple<Types...>, Alloc> : true_type { };
```

Requires: `Alloc` shall be an `Allocator` (17.165.0.1).

1

[*Note:* Specialization of this trait informs other library components that `tuple` can be constructed with an allocator, even though it does not have a nested `allocator_type`. — *end note*]

20.65.0.1 Tuple specialized algorithms [tuple.special]

```
template <class... Types>
  void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below);
```

1 *Remark:* The expression inside `noexcept` is equivalent to:

```
noexcept(x.swap(y))
```

2 *Effects:* `x.swap(y)`

20.66 Compile-time integer sequences [intseq]

20.66.1 In general [intseq.general]

1 The library provides a class template that can represent an integer sequence. When used as an argument to a function template the parameter pack defining the sequence can be deduced and used in a pack expansion.

2 [*Example:*

```
template<class F, class Tuple, std::size_t... I>
  decltype(auto) apply_impl(F&& f, Tuple&& t, index_sequence<I...>) {
    return std::forward<F>(f)(std::get<I>(std::forward<Tuple>(t))...);
  }

template<class F, class Tuple>
  decltype(auto) apply(F&& f, Tuple&& t) {
    using Indices = make_index_sequence<std::tuple_size<std::decay_t<Tuple>>::value>;
    return apply_impl(std::forward<F>(f), std::forward<Tuple>(t), Indices());
  }
```

— *end example*] [*Note:* The `index_sequence` alias template is provided for the common case of an integer sequence of type `size_t`. — *end note*]

20.66.2 Class template `integer_sequence` [intseq.intseq]

```
namespace std {
  template<class T, T... I>
  struct integer_sequence {
    typedef T value_type;
    static constexpr size_t size() noexcept { return sizeof...(I); }
  };
}
```

1 T shall be an integer type.

20.66.3 Alias template make_integer_sequence [intseq.make]

```
template<class T, T N>
  using make_integer_sequence = integer_sequence<T, see below>;
```

1

If N is negative the program is ill-formed. The alias template make_integer_sequence denotes a specialization of integer_sequence with N template non-type arguments. The type make_integer_sequence<T, N> denotes the type integer_sequence<T, 0, 1, ..., N-1>. [*Note:* make_integer_sequence<int, 0> denotes the type integer_sequence<int> — *end note*]

20.68 Class template bitset [template.bitset]

Header <bitset> synopsis

```
#include <string>
#include <iosfwd>                // for istream, ostream
namespace std {
  template <size_t N> class bitset;

  // 20.78.2 bitset operators:
  template <size_t N>
    bitset<N> operator&(const bitset<N>&, const bitset<N>&) noexcept;
  template <size_t N>
    bitset<N> operator|(const bitset<N>&, const bitset<N>&) noexcept;
  template <size_t N>
    bitset<N> operator^(const bitset<N>&, const bitset<N>&) noexcept;
  template <class charT, class traits, size_t N>
    basic_istream<charT, traits>&
    operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
  template <class charT, class traits, size_t N>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
}
```

1 The header <bitset> defines a class template and several related functions for representing and manipulating fixed-size sequences of bits.

```
namespace std {
  template<size_t N> class bitset {
  public:
    // bit reference:
    class reference {
      friend class bitset;
      reference() noexcept;
    public:
     ~reference() noexcept;
      reference& operator=(bool x) noexcept;              // for b[i] = x;
      reference& operator=(const reference&) noexcept;    // for b[i] = b[j];
      bool operator~() const noexcept;                    // flips the bit
      operator bool() const noexcept;                     // for x = b[i];
      reference& flip() noexcept;                         // for b[i].flip();
    };

    // 20.70.1 constructors:
```

```
  constexpr bitset() noexcept;
  constexpr bitset(unsigned long long val) noexcept;
  template<class charT, class traits, class Allocator>
    explicit bitset(
      const basic_string<charT,traits,Allocator>& str,
      typename basic_string<charT,traits,Allocator>::size_type pos = 0,
      typename basic_string<charT,traits,Allocator>::size_type n =
        basic_string<charT,traits,Allocator>::npos,
        charT zero = charT('0'), charT one = charT('1'));
  template <class charT>
    explicit bitset(
      const charT* str,
      typename basic_string<charT>::size_type n = basic_string<charT>::npos,
      charT zero = charT('0'), charT one = charT('1'));

  // 20.75.1 bitset operations:
  bitset<N>& operator&=(const bitset<N>& rhs) noexcept;
  bitset<N>& operator|=(const bitset<N>& rhs) noexcept;
  bitset<N>& operator^=(const bitset<N>& rhs) noexcept;
  bitset<N>& operator<<=(size_t pos) noexcept;
  bitset<N>& operator>>=(size_t pos) noexcept;
  bitset<N>& set() noexcept;
  bitset<N>& set(size_t pos, bool val = true);
  bitset<N>& reset() noexcept;
  bitset<N>& reset(size_t pos);
  bitset<N>  operator~() const noexcept;
  bitset<N>& flip() noexcept;
  bitset<N>& flip(size_t pos);

  // element access:
  constexpr bool operator[](size_t pos) const;       // for b[i];
  reference operator[](size_t pos);                  // for b[i];

  unsigned long to_ulong() const;
  unsigned long long to_ullong() const;
  template <class charT = char,
      class traits = char_traits<charT>,
      class Allocator = allocator<charT> >
    basic_string<charT, traits, Allocator>
    to_string(charT zero = charT('0'), charT one = charT('1')) const;
  size_t count() const noexcept;
  constexpr size_t size() const noexcept;
  bool operator==(const bitset<N>& rhs) const noexcept;
  bool operator!=(const bitset<N>& rhs) const noexcept;
  bool test(size_t pos) const;
  bool all() const noexcept;
  bool any() const noexcept;
  bool none() const noexcept;
  bitset<N> operator<<(size_t pos) const noexcept;
  bitset<N> operator>>(size_t pos) const noexcept;
};

// 20.78.1 hash support
template <class T> struct hash;
template <size_t N> struct hash<bitset<N> >;
```

```
}
```

2 The class template `bitset<N>`describes an object that can store a sequence consisting of a fixed number of bits, `N`.

3

Each bit represents either the value zero (reset) or one (set). To *toggle* a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position `pos`. When converting between an object of class `bitset<N>` and a value of some integral type, bit position `pos` corresponds to the *bit value* `1 <<pos`. The integral value corresponding to two or more bits is the sum of their bit values.

1 The functions described in this subclause can report three kinds of errors, each associated with a distinct exception:

(1.1) — an *invalid-argument* error is associated with exceptions of type `invalid_argument` (19.3.3);

(1.2) — an *out-of-range* error is associated with exceptions of type `out_of_range` (19.4.1);

(1.3) — an *overflow* error is associated with exceptions of type `overflow_error` (19.7.1).

20.70.1 `bitset` constructors [bitset.cons]

```
constexpr bitset() noexcept;
```

1

Effects: Constructs an object of class `bitset<N>`, initializing all bits to zero.

```
constexpr bitset(unsigned long long val) noexcept;
```

1

Effects: Constructs an object of class `bitset<N>`, initializing the first `M` bit positions to the corresponding bit values in `val`. `M` is the smaller of `N` and the number of bits in the value representation (3.2955) of `unsigned long long`. If `M < N`, the remaining bit positions are initialized to zero.

```
template <class charT, class traits, class Allocator>
explicit
bitset(const basic_string<charT, traits, Allocator>& str,
       typename basic_string<charT, traits, Allocator>::size_type pos = 0,
       typename basic_string<charT, traits, Allocator>::size_type n =
         basic_string<charT, traits, Allocator>::npos,
         charT zero = charT('0'), charT one = charT('1'));
```

1 *Requires:* `pos <= str.size()`.

2 *Throws:* `out_of_range` if `pos > str.size()`.

3 *Effects:* Determines the effective length `rlen` of the initializing string as the smaller of `n` and `str.size() - pos`.

The function then throws `invalid_argument` if any of the `rlen` characters in `str` beginning at position `pos` is other than `zero` or `one`. The function uses `traits::eq()` to compare the character values.

Otherwise, the function constructs an object of class `bitset<N>`, initializing the first `M` bit positions to values determined from the corresponding characters in the string `str`. `M` is the smaller of `N` and `rlen`.

4 An element of the constructed object has value zero if the corresponding character in `str`, beginning at position `pos`, is `zero`. Otherwise, the element has the value one. Character position `pos + M - 1` corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions.

5 If `M < N`, remaining bit positions are initialized to zero.

```
template <class charT>
  explicit bitset(
    const charT* str,
    typename basic_string<charT>::size_type n = basic_string<charT>::npos,
    charT zero = charT('0'), charT one = charT('1'));
```

6 *Effects:* Constructs an object of class `bitset<N>` as if by

```
bitset(
  n == basic_string<charT>::npos
    ? basic_string<charT>(str)
    : basic_string<charT>(str, n),
  0, n, zero, one)
```

20.75.1 `bitset` members [bitset.members]

`bitset<N>& operator&=(const bitset<N>& rhs) noexcept;`

1 *Effects:* Clears each bit in `*this` for which the corresponding bit in `rhs` is clear, and leaves all other bits unchanged.

2 *Returns:* `*this`.

`bitset<N>& operator|=(const bitset<N>& rhs) noexcept;`

3 *Effects:* Sets each bit in `*this` for which the corresponding bit in `rhs` is set, and leaves all other bits unchanged.

4 *Returns:* `*this`.

`bitset<N>& operator^=(const bitset<N>& rhs) noexcept;`

5 *Effects:* Toggles each bit in `*this` for which the corresponding bit in `rhs` is set, and leaves all other bits unchanged.

6 *Returns:* `*this`.

`bitset<N>& operator<<=(size_t pos) noexcept;`

7 *Effects:* Replaces each bit at position `I` in `*this` with a value determined as follows:

(7.1) — If `I < pos`, the new value is zero;

(7.2) — If `I >= pos`, the new value is the previous value of the bit at position `I - pos`.

8 *Returns:* `*this`.

`bitset<N>& operator>>=(size_t pos) noexcept;`

9 *Effects:* Replaces each bit at position `I` in `*this` with a value determined as follows:

(9.1) — If `pos >= N - I`, the new value is zero;

(9.2) — If `pos < N - I`, the new value is the previous value of the bit at position `I + pos`.

10 *Returns:* `*this`.

`bitset<N>& set() noexcept;`

11 *Effects:* Sets all bits in `*this`.

12 *Returns:* `*this`.

`bitset<N>& set(size_t pos, bool val = true);`

13 *Requires:* `pos` is valid

14 *Throws:* `out_of_range` if `pos` does not correspond to a valid bit position.

15 *Effects:* Stores a new value in the bit at position `pos` in `*this`. If `val` is nonzero, the stored value is one, otherwise it is zero.

16 *Returns:* `*this`.

```
bitset<N>& reset() noexcept;
```

17 *Effects:* Resets all bits in `*this`.

18 *Returns:* `*this`.

```
bitset<N>& reset(size_t pos);
```

19 *Requires:* `pos` is valid

20 *Throws:* `out_of_range` if `pos` does not correspond to a valid bit position.

21 *Effects:* Resets the bit at position `pos` in `*this`.

22 *Returns:* `*this`.

```
bitset<N> operator~() const noexcept;
```

23 *Effects:* Constructs an object `x` of class `bitset<N>` and initializes it with `*this`.

24 *Returns:* `x.flip()`.

```
bitset<N>& flip() noexcept;
```

25 *Effects:* Toggles all bits in `*this`.

26 *Returns:* `*this`.

```
bitset<N>& flip(size_t pos);
```

27 *Requires:* `pos` is valid

28 *Throws:* `out_of_range` if `pos` does not correspond to a valid bit position.

29 *Effects:* Toggles the bit at position `pos` in `*this`.

30 *Returns:* `*this`.

```
unsigned long to_ulong() const;
```

31 *Throws:* `overflow_error` if the integral value `x` corresponding to the bits in `*this` cannot be represented as type `unsigned long`.

32 *Returns:* `x`.

```
unsigned long long to_ullong() const;
```

33 *Throws:* `overflow_error` if the integral value `x` corresponding to the bits in `*this` cannot be represented as type `unsigned long long`.

34 *Returns:* `x`.

```
template <class charT = char,
    class traits = char_traits<charT>,
    class Allocator = allocator<charT> >
  basic_string<charT, traits, Allocator>
  to_string(charT zero = charT('0'), charT one = charT('1')) const;
```

35

Effects: Constructs a string object of the appropriate type and initializes it to a string of length `N` characters. Each character is determined by the value of its corresponding bit position in `*this`. Character position `N - 1` corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions. Bit value zero becomes the character `zero`, bit value one becomes the character `one`.

1 *Returns:* The created object.

```
size_t count() const noexcept;
```

2 *Returns:* A count of the number of bits set in `*this`.

```
constexpr size_t size() const noexcept;
```

3 *Returns:* `N`.

```
bool operator==(const bitset<N>& rhs) const noexcept;
```

4 *Returns:* `true` if the value of each bit in `*this` equals the value of the corresponding bit in `rhs`.

```
bool operator!=(const bitset<N>& rhs) const noexcept;
```

5 *Returns:* `true` if `!(*this == rhs)`.

```
bool test(size_t pos) const;
```

6 *Requires:* `pos` is valid

7 *Throws:* `out_of_range` if `pos` does not correspond to a valid bit position.

8 *Returns:* `true` if the bit at position `pos` in `*this` has the value one.

```
bool all() const noexcept;
```

9 *Returns:* `count() == size()`

```
bool any() const noexcept;
```

10 *Returns:* `count() != 0`

```
bool none() const noexcept;
```

11 *Returns:* `count() == 0`

```
bitset<N> operator<<(size_t pos) const noexcept;
```

12 *Returns:* `bitset<N>(*this) <<= pos`.

```
bitset<N> operator>>(size_t pos) const noexcept;
```

13 *Returns:* `bitset<N>(*this) >>= pos`.

```
constexpr bool operator[](size_t pos) const;
```

14 *Requires:* `pos` shall be valid.

15 *Returns:* `true` if the bit at position `pos` in `*this` has the value one, otherwise `false`.

16 *Throws:* Nothing.

```
bitset<N>::reference operator[](size_t pos);
```

17 *Requires:* `pos` shall be valid.

18

Returns: An object of type `bitset<N>::reference` such that `(*this)[pos] == this->test(pos)`, and such that `(*this)[pos] = val` is equivalent to `this->set(pos, val)`.

1 *Throws:* Nothing.

2

Remark: For the purpose of determining the presence of a data race (1.859), any access or update through the resulting reference potentially accesses or modifies, respectively, the entire underlying bitset.

20.78.1 `bitset` hash support [bitset.hash]

```
template <size_t N> struct hash<bitset<N> >;
```

1 The template specialization shall meet the requirements of class template `hash` (20.443.1).

20.78.2 `bitset` operators [bitset.operators]

```
bitset<N> operator&(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

1 *Returns:* `bitset<N>(lhs) &= rhs`.

```
bitset<N> operator|(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

2 *Returns:* `bitset<N>(lhs) |= rhs`.

```
bitset<N> operator^(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

3 *Returns:* `bitset<N>(lhs) ^= rhs`.

```
template <class charT, class traits, size_t N>
  basic_istream<charT, traits>&
  operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
```

4 A formatted input function (27.128.0.1).

5

Effects: Extracts up to `N` characters from `is`. Stores these characters in a temporary object `str` of type `basic_string<charT, traits>`, then evaluates the expression `x = bitset<N>(str)`. Characters are extracted and stored until any of the following occurs:

— `N` characters have been extracted and stored;

— end-of-file occurs on the input sequence;

— the next input character is neither `is.widen('0')` nor `is.widen('1')` (in which case the input character is not extracted).

1

If no characters are stored in `str`, calls `is.setstate(ios_base::failbit)` (which may throw `ios_base::failure` (27.84.0.1)).

1

Returns: `is`.

```
template <class charT, class traits, size_t N>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
```

1 *Returns:*

```
os << x.template to_string<charT,traits,allocator<charT> >(
  use_facet<ctype<charT> >(os.getloc()).widen('0'),
  use_facet<ctype<charT> >(os.getloc()).widen('1'))
```

(see 27.198.0.1).

20.82 Memory [memory]

20.82.1 In general [memory.general]

1 This subclause describes the contents of the header `<memory>` (20.82.2) and some of the contents of the C headers `<cstdlib>` and `<cstring>` (20.116.1).

20.82.2 Header `<memory>` synopsis [memory.syn]

1 The header `<memory>` defines several types and function templates that describe properties of pointers and pointer-like types, manage memory for containers and other template types, and construct multiple objects in uninitialized memory buffers (20.82.3–20.115.1). The header also defines the templates `unique_ptr`, `shared_ptr`, `weak_ptr`, and various function templates that operate on objects of these types (20.127).

```
namespace std {
  // 20.82.3, pointer traits
  template <class Ptr> struct pointer_traits;
  template <class T> struct pointer_traits<T*>;

  // 20.85.1, pointer safety
  enum class pointer_safety { relaxed, preferred, strict };
  void declare_reachable(void* p);
  template <class T> T* undeclare_reachable(T* p);
  void declare_no_pointers(char* p, size_t n);
  void undeclare_no_pointers(char* p, size_t n);
  pointer_safety get_pointer_safety() noexcept;

  // 20.85.2, pointer alignment function
  void* align(std::size_t alignment, std::size_t size,
    void*& ptr, std::size_t& space);

  // 20.86.1, allocator argument tag
  struct allocator_arg_t { };
  constexpr allocator_arg_t allocator_arg{};

  // 20.86.2, uses_allocator
  template <class T, class Alloc> struct uses_allocator;

  // 20.86.3, allocator traits
  template <class Alloc> struct allocator_traits;

  // 20.92.1, the default allocator:
  template <class T> class allocator;
  template <> class allocator<void>;
  template <class T, class U>
    bool operator==(const allocator<T>&, const allocator<U>&) noexcept;
  template <class T, class U>
    bool operator!=(const allocator<T>&, const allocator<U>&) noexcept;

  // 20.113.1, raw storage iterator:
```

```
template <class OutputIterator, class T> class raw_storage_iterator;

// 20.114.1, temporary buffers:
template <class T>
  pair<T*,ptrdiff_t> get_temporary_buffer(ptrdiff_t n) noexcept;
template <class T>
  void return_temporary_buffer(T* p);

// 20.115.1, specialized algorithms:
template <class T> T* addressof(T& r) noexcept;
template <class InputIterator, class ForwardIterator>
  ForwardIterator uninitialized_copy(InputIterator first, InputIterator last,
                                     ForwardIterator result);
template <class InputIterator, class Size, class ForwardIterator>
  ForwardIterator uninitialized_copy_n(InputIterator first, Size n,
                                       ForwardIterator result);
template <class ForwardIterator, class T>
  void uninitialized_fill(ForwardIterator first, ForwardIterator last,
                          const T& x);
template <class ForwardIterator, class Size, class T>
  ForwardIterator uninitialized_fill_n(ForwardIterator first, Size n, const T& x);

// 20.127.1 class template unique_ptr:
template <class T> struct default_delete;
template <class T> struct default_delete<T[]>;

  // D.59, auto_ptr (deprecated)
  template <class X> class auto_ptr;
}
```

20.82.3 Pointer traits [pointer.traits]

1 The class template `pointer_traits` supplies a uniform interface to certain attributes of pointer-like types.

```
namespace std {
  template <class Ptr> struct pointer_traits {
    typedef Ptr       pointer;
    typedef see below element_type;
    typedef see below difference_type;

    template <class U> using rebind = see below;

    static pointer pointer_to(see below r);
  };

  template <class T> struct pointer_traits<T*> {
    typedef T*        pointer;
    typedef T         element_type;
    typedef ptrdiff_t difference_type;

    template <class U> using rebind = U*;

    static pointer pointer_to(see below r) noexcept;
  };
}
```

20.82.3.1 Pointer traits member types [pointer.traits.types]

`typedef see below element_type;`

1 *Type:* `Ptr::element_type` if such a type exists; otherwise, `T` if `Ptr` is a class template instantiation of the form `SomePointer<T, Args>`, where `Args` is zero or more type arguments; otherwise, the specialization is ill-formed.

`typedef see below difference_type;`

1 *Type:* `Ptr::difference_type` if such a type exists; otherwise, `std::ptrdiff_t`.

`template <class U> using rebind = see below;`

2 *Alias template:* `Ptr::rebind<U>` if such a type exists; otherwise, `SomePointer<U, Args>` if `Ptr` is a class template instantiation of the form `SomePointer<T, Args>`, where `Args` is zero or more type arguments; otherwise, the instantiation of `rebind` is ill-formed.

20.85.0.1 Pointer traits member functions [pointer.traits.functions]

```
static pointer pointer_traits::pointer_to(see below r);
static pointer pointer_traits<T*>::pointer_to(see below r) noexcept;
```

1 *Remark:* If `element_type` is (possibly cv-qualified) `void`, the type of `r` is unspecified; otherwise, it is `element_type&`.

2 *Returns:* The first member function returns a pointer to `r` obtained by calling `Ptr::pointer_to(r)` through which indirection is valid; an instantiation of this function is ill-formed if `Ptr` does not have a matching `pointer_to` static member function. The second member function returns `std::addressof(r)`.

20.85.1 Pointer safety [util.dynamic.safety]

1 A complete object is *declared reachable* while the number of calls to `declare_reachable` with an argument referencing the object exceeds the number of calls to `undeclare_reachable` with an argument referencing the object.

`void declare_reachable(void* p);`

2 *Requires:* `p` shall be a safely-derived pointer (3.2532.0.1) or a null pointer value.

3 *Effects:* If `p` is not null, the complete object referenced by `p` is subsequently declared reachable (3.2532.0.1).

4 *Throws:* May throw `std::bad_alloc` if the system cannot allocate additional memory that may be required to track objects declared reachable.

`template <class T> T* undeclare_reachable(T* p);`

5 *Requires:* If `p` is not null, the complete object referenced by `p` shall have been previously declared reachable, and shall be live (3.2563) from the time of the call until the last `undeclare_reachable(p)` call on the object.

6 *Returns:* A safely derived copy of `p` which shall compare equal to `p`.

7 *Throws:* Nothing.

8 [*Note:* It is expected that calls to `declare_reachable(p)` will consume a small amount of memory in addition to that occupied by the referenced object until the matching call to `undeclare_reachable(p)` is encountered. Long running programs should arrange that calls are matched. — *end note*]

`void declare_no_pointers(char* p, size_t n);`

9 *Requires:* No bytes in the specified range are currently registered with `declare_no_pointers()`. If the specified range is in an allocated object, then it must be entirely within a single allocated object. The object must be live until the corresponding `undeclare_no_pointers()` call. [*Note:* In a garbage-collecting implementation, the fact that a region in an object is registered with `declare_no_pointers()` should not prevent the object from being collected. — *end note*]

10 *Effects:* The `n` bytes starting at `p` no longer contain traceable pointer locations, independent of their type. Hence indirection through a pointer located there is undefined if the object it points to was created by global `operator new` and not previously declared reachable. [*Note:* This may be used to inform a garbage collector or leak detector that this region of memory need not be traced. — *end note*]

11 *Throws:* Nothing.

12 [*Note:* Under some conditions implementations may need to allocate memory. However, the request can be ignored if memory allocation fails. — *end note*]

```
void undeclare_no_pointers(char* p, size_t n);
```

13 *Requires:* The same range must previously have been passed to `declare_no_pointers()`.

14 *Effects:* Unregisters a range registered with `declare_no_pointers()` for destruction. It must be called before the lifetime of the object ends.

15 *Throws:* Nothing.

```
pointer_safety get_pointer_safety() noexcept;
```

16 *Returns:* `pointer_safety::strict` if the implementation has strict pointer safety (3.2532.0.1). It is implementation defined whether `get_pointer_safety` returns `pointer_safety::relaxed` or `pointer_safety::preferred` if the implementation has relaxed pointer safety.[229]

20.85.2 Align [ptr.align]

```
void* align(std::size_t alignment, std::size_t size,
    void*& ptr, std::size_t& space);
```

1 *Effects:* If it is possible to fit `size` bytes of storage aligned by `alignment` into the buffer pointed to by `ptr` with length `space`, the function updates `ptr` to point to the first possible address of such storage and decreases `space` by the number of bytes used for alignment. Otherwise, the function does nothing.

2 *Requires:*

— `alignment` shall be a fundamental alignment value or an extended alignment value supported by the implementation in this context

— `ptr` shall point to contiguous storage of at least `space` bytes

1 *Returns:* A null pointer if the requested aligned buffer would not fit into the available space, otherwise the adjusted value of `ptr`.

2 [*Note:* The function updates its `ptr` and `space` arguments so that it can be called repeatedly with possibly different `alignment` and `size` arguments for the same buffer. — *end note*]

229) `pointer_safety::preferred` might be returned to indicate that a leak detector is running so that the program can avoid spurious leak reports.

20.86.1 Allocator argument tag [allocator.tag]

```
namespace std {
  struct allocator_arg_t { };
  constexpr allocator_arg_t allocator_arg{};
}
```

1 The `allocator_arg_t` struct is an empty structure type used as a unique type to disambiguate constructor and function overloading. Specifically, several types (see `tuple` 20.34) have constructors with `allocator_arg_t` as the first argument, immediately followed by an argument of a type that satisfies the `Allocator` requirements (17.165.0.1).

20.86.2 `uses_allocator` [allocator.uses]

20.86.2.1 `uses_allocator` trait [allocator.uses.trait]

```
template <class T, class Alloc> struct uses_allocator;
```

1 *Remark:* automatically detects whether `T` has a nested `allocator_type` that is convertible from `Alloc`. Meets the BinaryTypeTrait requirements (20.450.1). The implementation shall provide a definition that is derived from `true_type` if a type `T::allocator_type` exists and `is_convertible<Alloc, T::allocator_type>::value != false`, otherwise it shall be derived from `false_type`. A program may specialize this template to derive from `true_type` for a user-defined type `T` that does not have a nested `allocator_type` but nonetheless can be constructed with an allocator where either:

(1.1) — the first argument of a constructor has type `allocator_arg_t` and the second argument has type `Alloc` or

(1.2) — the last argument of a constructor has type `Alloc`.

20.86.2.2 uses-allocator construction [allocator.uses.construction]

1 *Uses-allocator construction* with allocator `Alloc` refers to the construction of an object `obj` of type `T`, using constructor arguments `v1, v2, ..., vN` of types `V1, V2, ..., VN`, respectively, and an allocator `alloc` of type `Alloc`, according to the following rules:

(1.1) — if `uses_allocator<T, Alloc>::value` is `false` and `is_constructible<T, V1, V2, ..., VN>::value` is `true`, then `obj` is initialized as `obj(v1, v2, ..., vN)`;

(1.2) — otherwise, if `uses_allocator<T, Alloc>::value` is `true` and `is_constructible<T, allocator_arg_t, Alloc, V1, V2, ..., VN>::value` is `true`, then `obj` is initialized as `obj(allocator_arg, alloc, v1, v2, ..., vN)`;

(1.3) — otherwise, if `uses_allocator<T, Alloc>::value` is `true` and `is_constructible<T, V1, V2, ..., VN, Alloc>::value` is `true`, then `obj` is initialized as `obj(v1, v2, ..., vN, alloc)`;

(1.4) — otherwise, the request for uses-allocator construction is ill-formed. [*Note:* An error will result if `uses_allocator<T, Alloc>::value` is `true` but the specific constructor does not take an allocator. This definition prevents a silent failure to pass the allocator to an element. — *end note*]

20.86.3 Allocator traits [allocator.traits]

1 The class template `allocator_traits` supplies a uniform interface to all allocator types. An allocator cannot be a non-class type, however, even if `allocator_traits` supplies the entire required interface. [*Note:* Thus, it is always possible to create a derived class from an allocator. — *end note*]

```
namespace std {
  template <class Alloc> struct allocator_traits {
    typedef Alloc allocator_type;
```

```
    typedef typename Alloc::value_type value_type;

    typedef see below pointer;
    typedef see below const_pointer;
    typedef see below void_pointer;
    typedef see below const_void_pointer;

    typedef see below difference_type;
    typedef see below size_type;

    typedef see below propagate_on_container_copy_assignment;
    typedef see below propagate_on_container_move_assignment;
    typedef see below propagate_on_container_swap;

    template <class T> using rebind_alloc = see below;
    template <class T> using rebind_traits = allocator_traits<rebind_alloc<T> >;

    static pointer allocate(Alloc& a, size_type n);
    static pointer allocate(Alloc& a, size_type n, const_void_pointer hint);

    static void deallocate(Alloc& a, pointer p, size_type n);

    template <class T, class... Args>
      static void construct(Alloc& a, T* p, Args&&... args);

    template <class T>
      static void destroy(Alloc& a, T* p);

    static size_type max_size(const Alloc& a) noexcept;

    static Alloc select_on_container_copy_construction(const Alloc& rhs);
  };
}
```

20.86.3.1 Allocator traits member types [allocator.traits.types]

`typedef see below pointer;`

1 *Type:* `Alloc::pointer` if such a type exists; otherwise, `value_type*`.

`typedef see below const_pointer;`

2 *Type:* `Alloc::const_pointer` if such a type exists; otherwise, `pointer_traits<pointer>::rebind<const value_type>`.

`typedef see below void_pointer;`

3 *Type:* `Alloc::void_pointer` if such a type exists; otherwise, `pointer_traits<pointer>::rebind<void>`.

`typedef see below const_void_pointer;`

4 *Type:* `Alloc::const_void_pointer` if such a type exists; otherwise, `pointer_traits<pointer>::rebind<const void>`.

`typedef see below difference_type;`

5 *Type:* `Alloc::difference_type` if such a type exists; otherwise, `pointer_traits<pointer>::difference_type`.

```
typedef see below size_type;
```

6 *Type:* `Alloc::size_type` if such a type exists; otherwise, `make_unsigned_t<difference_type>`.

```
typedef see below propagate_on_container_copy_assignment;
```

7 *Type:* `Alloc::propagate_on_container_copy_assignment` if such a type exists, otherwise `false_type`.

```
typedef see below propagate_on_container_move_assignment;
```

8 *Type:* `Alloc::propagate_on_container_move_assignment` if such a type exists, otherwise `false_type`.

```
typedef see below propagate_on_container_swap;
```

1 *Type:* `Alloc::propagate_on_container_swap` if such a type exists, otherwise `false_type`.

```
template <class T> using rebind_alloc = see below;
```

2 *Alias template:* `Alloc::rebind<T>::other` if such a type exists; otherwise, `Alloc<T, Args>` if `Alloc` is a class template instantiation of the form `Alloc<U, Args>`, where `Args` is zero or more type arguments; otherwise, the instantiation of `rebind_alloc` is ill-formed.

20.89.0.1 Allocator traits static member functions [allocator.traits.members]

```
static pointer allocate(Alloc& a, size_type n);
```

1 *Returns:* `a.allocate(n)`.

```
static pointer allocate(Alloc& a, size_type n, const_void_pointer hint);
```

2 *Returns:* `a.allocate(n, hint)` if that expression is well-formed; otherwise, `a.allocate(n)`.

```
static void deallocate(Alloc& a, pointer p, size_type n);
```

3 *Effects:* calls `a.deallocate(p, n)`.

4 *Throws:* Nothing.

```
template <class T, class... Args>
  static void construct(Alloc& a, T* p, Args&&... args);
```

5 *Effects:* calls `a.construct(p, std::forward<Args>(args)...)` if that call is well-formed; otherwise, invokes `::new (static_cast<void*>(p)) T(std::forward<Args>(args)...)`.

```
template <class T>
  static void destroy(Alloc& a, T* p);
```

1 *Effects:* calls `a.destroy(p)` if that call is well-formed; otherwise, invokes `p->~T()`.

```
static size_type max_size(const Alloc& a) noexcept;
```

2 *Returns:* `a.max_size()` if that expression is well-formed; otherwise, `numeric_limits<size_type>::max()`.

```
static Alloc select_on_container_copy_construction(const Alloc& rhs);
```

3 *Returns:* `rhs.select_on_container_copy_construction()` if that expression is well-formed; otherwise, `rhs`.

20.92.1 The default allocator [default.allocator]

```
namespace std {
  template <class T> class allocator;

  // specialize for void:
  template <> class allocator<void> {
  public:
    typedef void*   pointer;
    typedef const void* const_pointer;
    // reference-to-void members are impossible.
    typedef void  value_type;
    template <class U> struct rebind { typedef allocator<U> other; };
  };

  template <class T> class allocator {
   public:
    typedef size_t    size_type;
    typedef ptrdiff_t difference_type;
    typedef T*        pointer;
    typedef const T*  const_pointer;
    typedef T&        reference;
    typedef const T&  const_reference;
    typedef T         value_type;
    template <class U> struct rebind { typedef allocator<U> other; };
    typedef true_type propagate_on_container_move_assignment;

    allocator() noexcept;
    allocator(const allocator&) noexcept;
    template <class U> allocator(const allocator<U>&) noexcept;
   ~allocator();

    pointer address(reference x) const noexcept;
    const_pointer address(const_reference x) const noexcept;

    pointer allocate(
      size_type, allocator<void>::const_pointer hint = 0);
    void deallocate(pointer p, size_type n);
    size_type max_size() const noexcept;

    template<class U, class... Args>
      void construct(U* p, Args&&... args);
    template <class U>
      void destroy(U* p);
  };
}
```

20.92.1.1 `allocator` members [allocator.members]

1

Except for the destructor, member functions of the default allocator shall not introduce data races (1.859) as a result of concurrent calls to those member functions from different threads. Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before the next allocation (if any) in this order.

```
pointer address(reference x) const noexcept;
```

1 *Returns:* The actual address of the object referenced by `x`, even in the presence of an overloaded operator&.

```
const_pointer address(const_reference x) const noexcept;
```

2

Returns: The actual address of the object referenced by `x`, even in the presence of an overloaded operator&.

```
pointer allocate(size_type n, allocator<void>::const_pointer hint = 0);
```

1 [*Note:* In a container member function, the address of an adjacent element is often a good choice to pass for the `hint` argument. — *end note*]

2

Returns: A pointer to the initial element of an array of storage of size `n * sizeof(T)`, aligned appropriately for objects of type `T`. It is implementation-defined whether over-aligned types are supported (3.3924).

1

Remark: the storage is obtained by calling `::operator new(std::size_t)` (18.159.1), but it is unspecified when or how often this function is called. The use of `hint` is unspecified, but intended as an aid to locality if an implementation so desires.

1 *Throws:* `bad_alloc` if the storage cannot be obtained.

```
void deallocate(pointer p, size_type n);
```

2

Requires: `p` shall be a pointer value obtained from `allocate()`. `n` shall equal the value passed as the first argument to the invocation of allocate which returned `p`.

1 *Effects:* Deallocates the storage referenced by `p` .

2

Remarks: Uses `::operator delete(void*, std::size_t)` (18.159.1), but it is unspecified when this function is called.

```
size_type max_size() const noexcept;
```

1

Returns: The largest value N for which the call `allocate(N,0)` might succeed.

```
template <class U, class... Args>
  void construct(U* p, Args&&... args);
```

1 *Effects:* `::new((void *)p) U(std::forward<Args>(args)...)`

```
template <class U>
  void destroy(U* p);
```

2 *Effects:* `p->~U()`

20.113.0.1 `allocator` globals [allocator.globals]

```
template <class T1, class T2>
  bool operator==(const allocator<T1>&, const allocator<T2>&) noexcept;
```

1 *Returns:* `true`.

```
template <class T1, class T2>
  bool operator!=(const allocator<T1>&, const allocator<T2>&) noexcept;
```

2 *Returns:* `false`.

20.113.1 Raw storage iterator [storage.iterator]

1

`raw_storage_iterator` is provided to enable algorithms to store their results into uninitialized memory. The template parameter `OutputIterator` is required to have its `operator*` return an object for which `operator&` is defined and returns a pointer to `T`, and is also required to satisfy the requirements of an output iterator (24.116.1).

```
namespace std {
  template <class OutputIterator, class T>
  class raw_storage_iterator
    : public iterator<output_iterator_tag,void,void,void,void> {
  public:
    explicit raw_storage_iterator(OutputIterator x);

    raw_storage_iterator& operator*();
    raw_storage_iterator& operator=(const T& element);
    raw_storage_iterator& operator++();
    raw_storage_iterator  operator++(int);
  };
}
```

`explicit raw_storage_iterator(OutputIterator x);`

1 *Effects:* Initializes the iterator to point to the same value to which `x` points.

`raw_storage_iterator& operator*();`

2 *Returns:* `*this`

`raw_storage_iterator& operator=(const T& element);`

3 *Effects:* Constructs a value from `element` at the location to which the iterator points.

4 *Returns:* A reference to the iterator.

`raw_storage_iterator& operator++();`

5 *Effects:* Pre-increment: advances the iterator and returns a reference to the updated iterator.

`raw_storage_iterator operator++(int);`

6 *Effects:* Post-increment: advances the iterator and returns the old value of the iterator.

20.114.1 Temporary buffers [temporary.buffer]

```
template <class T>
  pair<T*, ptrdiff_t> get_temporary_buffer(ptrdiff_t n) noexcept;
```

1

Effects: Obtains a pointer to storage sufficient to store up to `n` adjacent `T` objects. It is implementation-defined whether over-aligned types are supported (3.3924).

1 *Returns:* A `pair` containing the buffer's address and capacity (in the units of `sizeof(T)`), or a pair of 0 values if no storage can be obtained or if `n <= 0`.

```
template <class T> void return_temporary_buffer(T* p);
```

2 *Effects:* Deallocates the buffer to which `p` points.

3 *Requires:* The buffer shall have been previously allocated by `get_temporary_buffer`.

20.115.1 Specialized algorithms [specialized.algorithms]

1

All the iterators that are used as template parameters in the following algorithms are required to have their `operator*` return an object for which `operator&` is defined and returns a pointer to `T`. In the algorithm `uninitialized_copy`, the template parameter `InputIterator` is required to satisfy the requirements of an input iterator (24.100.1). In all of the following algorithms, the template parameter `ForwardIterator` is required to satisfy the requirements of a forward iterator (24.122.1), and is required to have the property that no exceptions are thrown from increment, assignment, comparison, or indirection through valid iterators. In the following algorithms, if an exception is thrown there are no effects.

20.116.0.1 `addressof` [specialized.addressof]

```
template <class T> T* addressof(T& r) noexcept;
```

1 *Returns:* The actual address of the object or function referenced by `r`, even in the presence of an overloaded `operator&`.

20.116.0.2 `uninitialized_copy` [uninitialized.copy]

```
template <class InputIterator, class ForwardIterator>
  ForwardIterator uninitialized_copy(InputIterator first, InputIterator last,
                                     ForwardIterator result);
```

1 *Effects:*

```
for (; first != last; ++result, ++first)
  ::new (static_cast<void*>(&*result))
    typename iterator_traits<ForwardIterator>::value_type(*first);
```

2 *Returns:* `result`

```
template <class InputIterator, class Size, class ForwardIterator>
  ForwardIterator uninitialized_copy_n(InputIterator first, Size n,
                                       ForwardIterator result);
```

3 *Effects:*

```
for ( ; n > 0; ++result, ++first, --n) {
  ::new (static_cast<void*>(&*result))
    typename iterator_traits<ForwardIterator>::value_type(*first);
}
```

4 *Returns:* `result`

20.116.0.3 uninitialized_fill [uninitialized.fill]

```
template <class ForwardIterator, class T>
  void uninitialized_fill(ForwardIterator first, ForwardIterator last,
                          const T& x);
```

1 *Effects:*

```
for (; first != last; ++first)
  ::new (static_cast<void*>(&*first))
    typename iterator_traits<ForwardIterator>::value_type(x);
```

20.116.0.4 uninitialized_fill_n [uninitialized.fill.n]

```
template <class ForwardIterator, class Size, class T>
  ForwardIterator uninitialized_fill_n(ForwardIterator first, Size n, const T& x);
```

1 *Effects:*

```
for (; n--; ++first)
  ::new (static_cast<void*>(&*first))
    typename iterator_traits<ForwardIterator>::value_type(x);
return first;
```

20.116.1 C library [c.malloc]

1 Table 45 describes the header `<cstdlib>`.

Table 45 — Header `<cstdlib>` synopsis

Type	Name(s)	
Functions:	`calloc`	`malloc`
	`free`	`realloc`

2

The contents are the same as the Standard C library header `<stdlib.h>`, with the following changes:

1

The functions `calloc()`, `malloc()`, and `realloc()` do not attempt to allocate storage by calling `::operator new()` (18.159).

1

The function `free()` does not attempt to deallocate storage by calling `::operator delete()`.

See also: ISO C Clause 7.11.2.

1

Storage allocated directly with `malloc()`, `calloc()`, or `realloc()` is implicitly declared reachable (see 3.2532.0.1) on allocation, ceases to be declared reachable on deallocation, and need not cease to be declared reachable as the result of an `undeclare_reachable()` call. [*Note:* This allows existing C libraries to remain unaffected by restrictions on pointers that are not safely derived, at the expense of providing far fewer garbage collection and leak detection options for `malloc()`-allocated objects. It also allows `malloc()` to be implemented with a separate allocation arena, bypassing the normal `declare_reachable()` implementation. The above functions should never intentionally be used as a replacement for `declare_reachable()`, and newly written code is strongly encouraged to treat memory allocated with these functions as though it were allocated with `operator new`. — *end note*]

Table 46 — Header `<cstring>` synopsis

Type	Name(s)	
Macro:	`NULL`	
Type:	`size_t`	
Functions:	`memchr`	`memcmp`
`memcpy`	`memmove`	`memset`

1 Table 46 describes the header `<cstring>`.

2

The contents are the same as the Standard C library header `<string.h>`, with the change to `memchr()` specified in 21.261.

See also: ISO C Clause 7.11.2.

20.127 Smart pointers [smartptr]

20.127.1 Class template `unique_ptr` [unique.ptr]

1

A *unique pointer* is an object that owns another object and manages that other object through a pointer. More precisely, a unique pointer is an object *u* that stores a pointer to a second object *p* and will dispose of *p* when *u* is itself destroyed (e.g., when leaving block scope (6.419)). In this context, *u* is said to *own* `p`.

1 The mechanism by which *u* disposes of *p* is known as *p*'s associated *deleter*, a function object whose correct invocation results in *p*'s appropriate disposition (typically its deletion).

2 Let the notation *u.p* denote the pointer stored by *u*, and let *u.d* denote the associated deleter. Upon request, *u* can *reset* (replace) *u.p* and *u.d* with another pointer and deleter, but must properly dispose of its owned object via the associated deleter before such replacement is considered completed.

3

Additionally, *u* can, upon request, *transfer ownership* to another unique pointer *u2*. Upon completion of such a transfer, the following postconditions hold:

— *u2.p* is equal to the pre-transfer *u.p*,

— *u.p* is equal to `nullptr`, and

— if the pre-transfer *u.d* maintained state, such state has been transferred to *u2.d*.

As in the case of a reset, *u2* must properly dispose of its pre-transfer owned object via the pre-transfer associated deleter before the ownership transfer is considered complete. [*Note:* A deleter's state need never be copied, only moved or swapped as ownership is transferred. — *end note*]

1

Each object of a type `U` instantiated from the `unique_ptr` template specified in this subclause has the strict ownership semantics, specified above, of a unique pointer. In partial satisfaction of these semantics, each such `U` is `MoveConstructible` and `MoveAssignable`, but is not `CopyConstructible` nor `CopyAssignable`. The template parameter `T` of `unique_ptr` may be an incomplete type.

1 [*Note:* The uses of `unique_ptr` include providing exception safety for dynamically allocated memory, passing ownership of dynamically allocated memory to a function, and returning dynamically allocated memory from a function. — *end note*]

```
namespace std {
```

```
template<class T> struct default_delete;
template<class T> struct default_delete<T[]>;

template<class T, class D = default_delete<T>> class unique_ptr;
template<class T, class D> class unique_ptr<T[], D>;

template<class T, class... Args> unique_ptr<T> make_unique(Args&&... args);
template<class T> unique_ptr<T> make_unique(size_t n);
template<class T, class... Args> unspecified  make_unique(Args&&...) = delete;

template<class T, class D> void swap(unique_ptr<T, D>& x, unique_ptr<T, D>& y) noexcept;

template<class T1, class D1, class T2, class D2>
  bool operator==(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
template<class T1, class D1, class T2, class D2>
  bool operator!=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
template<class T1, class D1, class T2, class D2>
  bool operator<(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
template<class T1, class D1, class T2, class D2>
  bool operator<=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
template<class T1, class D1, class T2, class D2>
  bool operator>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
template<class T1, class D1, class T2, class D2>
  bool operator>=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

template <class T, class D>
  bool operator==(const unique_ptr<T, D>& x, nullptr_t) noexcept;
template <class T, class D>
  bool operator==(nullptr_t, const unique_ptr<T, D>& y) noexcept;
template <class T, class D>
  bool operator!=(const unique_ptr<T, D>& x, nullptr_t) noexcept;
template <class T, class D>
  bool operator!=(nullptr_t, const unique_ptr<T, D>& y) noexcept;
template <class T, class D>
  bool operator<(const unique_ptr<T, D>& x, nullptr_t);
template <class T, class D>
  bool operator<(nullptr_t, const unique_ptr<T, D>& y);
template <class T, class D>
  bool operator<=(const unique_ptr<T, D>& x, nullptr_t);
template <class T, class D>
  bool operator<=(nullptr_t, const unique_ptr<T, D>& y);
template <class T, class D>
  bool operator>(const unique_ptr<T, D>& x, nullptr_t);
template <class T, class D>
  bool operator>(nullptr_t, const unique_ptr<T, D>& y);
template <class T, class D>
  bool operator>=(const unique_ptr<T, D>& x, nullptr_t);
template <class T, class D>
  bool operator>=(nullptr_t, const unique_ptr<T, D>& y);

}
```

20.141.0.1 Default deleters [unique.ptr.dltr]

20.141.0.1.1 In general [unique.ptr.dltr.general]

1

The class template `default_delete` serves as the default deleter (destruction policy) for the class template `unique_ptr`.

1

The template parameter `T` of `default_delete` may be an incomplete type.

20.144.0.0.1 `default_delete` [unique.ptr.dltr.dflt]

```
namespace std {
  template <class T> struct default_delete {
    constexpr default_delete() noexcept = default;
    template <class U> default_delete(const default_delete<U>&) noexcept;
    void operator()(T*) const;
  };
}
```

`template <class U> default_delete(const default_delete<U>& other) noexcept;`

1 *Effects:* Constructs a `default_delete` object from another `default_delete<U>` object.

2 *Remarks:* This constructor shall not participate in overload resolution unless `U*` is implicitly convertible to `T*`.

`void operator()(T* ptr) const;`

3 *Effects:* calls `delete` on `ptr`.

4 *Remarks:* If `T` is an incomplete type, the program is ill-formed.

20.144.0.0.2 `default_delete<T[]>` [unique.ptr.dltr.dflt1]

```
namespace std {
  template <class T> struct default_delete<T[]> {
    constexpr default_delete() noexcept = default;
    void operator()(T*) const;
    template <class U> void operator()(U*) const = delete;
  };
}
```

`void operator()(T* ptr) const;`

1 *Effects:* calls `delete[]` on `ptr`.

2 *Remarks:* If T is an incomplete type, the program is ill-formed.

20.144.0.1 `unique_ptr` for single objects [unique.ptr.single]

```
namespace std {
  template <class T, class D = default_delete<T>> class unique_ptr {
  public:
    typedef see below pointer;
    typedef T element_type;
    typedef D deleter_type;

    // 20.150.0.0.1, constructors
```

```
    constexpr unique_ptr() noexcept;
    explicit unique_ptr(pointer p) noexcept;
    unique_ptr(pointer p, see below d1) noexcept;
    unique_ptr(pointer p, see below d2) noexcept;
    unique_ptr(unique_ptr&& u) noexcept;
    constexpr unique_ptr(nullptr_t) noexcept
      : unique_ptr() { }
    template <class U, class E>
      unique_ptr(unique_ptr<U, E>&& u) noexcept;
    template <class U>
      unique_ptr(auto_ptr<U>&& u) noexcept;

    // 20.157.0.0.1, destructor
    ~unique_ptr();

    // 20.165.0.0.1, assignment
    unique_ptr& operator=(unique_ptr&& u) noexcept;
    template <class U, class E> unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
    unique_ptr& operator=(nullptr_t) noexcept;

    // 20.170.0.0.1, observers
    add_lvalue_reference_t<T> operator*() const;
    pointer operator->() const noexcept;
    pointer get() const noexcept;
    deleter_type& get_deleter() noexcept;
    const deleter_type& get_deleter() const noexcept;
    explicit operator bool() const noexcept;

    // 20.171.0.0.1 modifiers
    pointer release() noexcept;
    void reset(pointer p = pointer()) noexcept;
    void swap(unique_ptr& u) noexcept;

    // disable copy from lvalue
    unique_ptr(const unique_ptr&) = delete;
    unique_ptr& operator=(const unique_ptr&) = delete;
  };
}
```

1

The default type for the template parameter `D` is `default_delete`. A client-supplied template argument `D` shall be a function object type (20.283), lvalue-reference to function, or lvalue-reference to function object type for which, given a value `d` of type `D` and a value `ptr` of type `unique_ptr<T, D>::pointer`, the expression `d(ptr)` is valid and has the effect of disposing of the pointer as appropriate for that deleter.

1 If the deleter's type `D` is not a reference type, `D` shall satisfy the requirements of `Destructible` (Table 24).

2

If the type `remove_reference_t<D>::pointer` exists, then `unique_ptr<T, D>::pointer` shall be a synonym for `remove_reference_t<D>::pointer`. Otherwise `unique_ptr<T, D>::pointer` shall be a synonym for `T*`. The type `unique_ptr<T, D>::pointer` shall satisfy the requirements of `NullablePointer` (17.153.0.1).

1 [*Example:* Given an allocator type `X` (17.165.0.1) and letting `A` be a synonym for `allocator_traits<X>`, the types `A::pointer`, `A::const_pointer`, `A::void_pointer`, and `A::const_void_pointer` may be used

as `unique_ptr<T, D>::pointer`. — *end example*]

20.150.0.0.1 `unique_ptr` constructors [unique.ptr.single.ctor]

`constexpr unique_ptr() noexcept;`

1 *Requires:* `D` shall satisfy the requirements of `DefaultConstructible` (Table 19), and that construction shall not throw an exception.

2 *Effects:* Constructs a `unique_ptr` object that owns nothing, value-initializing the stored pointer and the stored deleter.

1 *Postconditions:* `get() == nullptr`. `get_deleter()` returns a reference to the stored deleter.

2 *Remarks:* If this constructor is instantiated with a pointer type or reference type for the template argument `D`, the program is ill-formed.

`explicit unique_ptr(pointer p) noexcept;`

1 *Requires:* `D` shall satisfy the requirements of `DefaultConstructible` (Table 19), and that construction shall not throw an exception.

2 *Effects:* Constructs a `unique_ptr` which owns `p`, initializing the stored pointer with `p` and value-initializing the stored deleter.

3 *Postconditions:* `get() == p`. `get_deleter()` returns a reference to the stored deleter.

4 *Remarks:* If this constructor is instantiated with a pointer type or reference type for the template argument `D`, the program is ill-formed.

```
unique_ptr(pointer p, see below d1) noexcept;
unique_ptr(pointer p, see below d2) noexcept;
```

5 The signature of these constructors depends upon whether `D` is a reference type. If `D` is non-reference type `A`, then the signatures are:

```
unique_ptr(pointer p, const A& d);
unique_ptr(pointer p, A&& d);
```

1 If `D` is an lvalue-reference type `A&`, then the signatures are:

```
unique_ptr(pointer p, A& d);
unique_ptr(pointer p, A&& d);
```

2 If `D` is an lvalue-reference type `const A&`, then the signatures are:

```
unique_ptr(pointer p, const A& d);
unique_ptr(pointer p, const A&& d);
```

3 *Requires:*

(3.1) — If `D` is not an lvalue-reference type then

(3.1.1) — If `d` is an lvalue or `const` rvalue then the first constructor of this pair will be selected. `D` shall satisfy the requirements of `CopyConstructible` (Table 21), and the copy constructor of `D` shall not throw an exception. This `unique_ptr` will hold a copy of `d`.

(3.1.2) — Otherwise, `d` is a non-const rvalue and the second constructor of this pair will be selected. `D` shall satisfy the requirements of `MoveConstructible` (Table 20), and the move constructor of `D` shall not throw an exception. This `unique_ptr` will hold a value move constructed from `d`.

(3.2) — Otherwise `D` is an lvalue-reference type. `d` shall be reference-compatible with one of the constructors. If `d` is an rvalue, it will bind to the second constructor of this pair and the program is ill-formed. [*Note:* The diagnostic could be implemented using a `static_assert` which assures that `D` is not a reference type. — *end note*] Else `d` is an lvalue and will bind to the first constructor of this pair. The type which `D` references need not be `CopyConstructible` nor `MoveConstructible`. This `unique_ptr` will hold a `D` which refers to the lvalue `d`. [*Note:* `D` may not be an rvalue-reference type. — *end note*]

4 *Effects:* Constructs a `unique_ptr` object which owns `p`, initializing the stored pointer with `p` and initializing the deleter as described above.

5 *Postconditions:* `get() == p`. `get_deleter()` returns a reference to the stored deleter. If `D` is a reference type then `get_deleter()` returns a reference to the lvalue `d`.

[*Example:*

```
D d;
unique_ptr<int, D> p1(new int, D());        // D must be MoveConstructible
unique_ptr<int, D> p2(new int, d);          // D must be CopyConstructible
unique_ptr<int, D&> p3(new int, d);         // p3 holds a reference to d
unique_ptr<int, const D&> p4(new int, D()); // error: rvalue deleter object combined
                                            // with reference deleter type
```

— *end example*]

`unique_ptr(unique_ptr&& u) noexcept;`

6 *Requires:* If `D` is not a reference type, `D` shall satisfy the requirements of `MoveConstructible` (Table 20). Construction of the deleter from an rvalue of type `D` shall not throw an exception.

7

Effects: Constructs a `unique_ptr` by transferring ownership from `u` to `*this`. If `D` is a reference type, this deleter is copy constructed from `u`'s deleter; otherwise, this deleter is move constructed from `u`'s deleter. [*Note:* The deleter constructor can be implemented with `std::forward<D>`. — *end note*]

1 *Postconditions:* `get()` yields the value `u.get()` yielded before the construction. `get_deleter()` returns a reference to the stored deleter that was constructed from `u.get_deleter()`. If `D` is a reference type then `get_deleter()` and `u.get_deleter()` both reference the same lvalue deleter.

`template <class U, class E> unique_ptr(unique_ptr<U, E>&& u) noexcept;`

2 *Requires:* If `E` is not a reference type, construction of the deleter from an rvalue of type `E` shall be well formed and shall not throw an exception. Otherwise, `E` is a reference type and construction of the deleter from an lvalue of type `E` shall be well formed and shall not throw an exception.

3 *Remarks:* This constructor shall not participate in overload resolution unless:

(3.1) — `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer`,

(3.2) — `U` is not an array type, and

(3.3) — either `D` is a reference type and `E` is the same type as `D`, or `D` is not a reference type and `E` is implicitly convertible to `D`.

4 *Effects:* Constructs a `unique_ptr` by transferring ownership from `u` to `*this`. If `E` is a reference type, this deleter is copy constructed from `u`'s deleter; otherwise, this deleter is move constructed from `u`'s deleter. [*Note:* The deleter constructor can be implemented with `std::forward<E>`. — *end note*]

5 *Postconditions:* `get()` yields the value `u.get()` yielded before the construction. `get_deleter()` returns a reference to the stored deleter that was constructed from `u.get_deleter()`.

```
template <class U>
  unique_ptr(auto_ptr<U>&& u) noexcept;
```

6 *Effects:* Constructs a `unique_ptr` object, initializing the stored pointer with `u.release()` and value-initializing the stored deleter.

7 *Postconditions:* `get()` yields the value `u.get()` yielded before the construction. `u.get() == nullptr`. `get_deleter()` returns a reference to the stored deleter.

8

Remarks: This constructor shall not participate in overload resolution unless `U*` is implicitly convertible to `T*` and `D` is the same type as `default_delete<T>`.

20.157.0.0.1 `unique_ptr` destructor [unique.ptr.single.dtor]

```
~unique_ptr();
```

1

Requires: The expression `get_deleter()(get())` shall be well formed, shall have well-defined behavior, and shall not throw exceptions. [*Note:* The use of `default_delete` requires `T` to be a complete type. — *end note*]

1

Effects: If `get() == nullptr` there are no effects. Otherwise `get_deleter()(get())`.

20.165.0.0.1 `unique_ptr` assignment [unique.ptr.single.asgn]

```
unique_ptr& operator=(unique_ptr&& u) noexcept;
```

1

Requires: If `D` is not a reference type, `D` shall satisfy the requirements of `MoveAssignable` (Table 22) and assignment of the deleter from an rvalue of type `D` shall not throw an exception. Otherwise, `D` is a reference type; `remove_reference_t<D>` shall satisfy the `CopyAssignable` requirements and assignment of the deleter from an lvalue of type `D` shall not throw an exception.

1

Effects: Transfers ownership from `u` to `*this` as if by calling `reset(u.release())` followed by `get_deleter() = std::forward<D>(u.get_deleter())`.

1 *Returns:* `*this`.

```
template <class U, class E> unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
```

2 *Requires:* If `E` is not a reference type, assignment of the deleter from an rvalue of type `E` shall be well-formed and shall not throw an exception. Otherwise, `E` is a reference type and assignment of the deleter from an lvalue of type `E` shall be well-formed and shall not throw an exception.

3 *Remarks:* This operator shall not participate in overload resolution unless:

(3.1) — `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer` and

(3.2) — `U` is not an array type.

4 *Effects:* Transfers ownership from `u` to `*this` as if by calling `reset(u.release())` followed by `get_deleter() = std::forward<E>(u.get_deleter())`.

5 *Returns:* `*this`.

```
unique_ptr& operator=(nullptr_t) noexcept;
```

6 *Effects:* `reset()`.

7 *Postcondition:* `get() == nullptr`

8 *Returns:* `*this`.

20.170.0.0.1 `unique_ptr` observers [unique.ptr.single.observers]

```
add_lvalue_reference_t<T> operator*() const;
```

1 *Requires:* `get() != nullptr`.

2 *Returns:* `*get()`.

```
pointer operator->() const noexcept;
```

3 *Requires:* `get() != nullptr`.

4 *Returns:* `get()`.

5

Note: use typically requires that `T` be a complete type.

```
pointer get() const noexcept;
```

1 *Returns:* The stored pointer.

```
deleter_type& get_deleter() noexcept;
const deleter_type& get_deleter() const noexcept;
```

2 *Returns:* A reference to the stored deleter.

```
explicit operator bool() const noexcept;
```

3 *Returns:* `get() != nullptr`.

20.171.0.0.1 `unique_ptr` modifiers [unique.ptr.single.modifiers]

```
pointer release() noexcept;
```

1 *Postcondition:* `get() == nullptr`.

2

Returns: The value `get()` had at the start of the call to `release`.

```
void reset(pointer p = pointer()) noexcept;
```

1 *Requires:* The expression `get_deleter()(get())` shall be well formed, shall have well-defined behavior, and shall not throw exceptions.

2

Effects: assigns `p` to the stored pointer, and then if the old value of the stored pointer, `old_p`, was not equal to `nullptr`, calls `get_deleter()(old_p)`. [*Note:* The order of these operations is significant because the call to `get_deleter()` may destroy `*this`. — *end note*]

1 *Postconditions:* `get() == p`. [*Note:* The postcondition does not hold if the call to `get_deleter()` destroys `*this` since `this->get()` is no longer a valid expression. — *end note*]

```
void swap(unique_ptr& u) noexcept;
```

2 *Requires:* `get_deleter()` shall be swappable (17.143.0.1) and shall not throw an exception under `swap`.

3 *Effects:* Invokes `swap` on the stored pointers and on the stored deleters of `*this` and `u`.

20.177.0.1 unique_ptr for array objects with a runtime length [unique.ptr.runtime]

```
namespace std {
  template <class T, class D> class unique_ptr<T[], D> {
  public:
    typedef see below pointer;
    typedef T element_type;
    typedef D deleter_type;

    // 20.178.0.0.1, constructors
    constexpr unique_ptr() noexcept;
    explicit unique_ptr(pointer p) noexcept;
    unique_ptr(pointer p, see below d) noexcept;
    unique_ptr(pointer p, see below d) noexcept;
    unique_ptr(unique_ptr&& u) noexcept;
    constexpr unique_ptr(nullptr_t) noexcept : unique_ptr() { }

    // destructor
    ~unique_ptr();

    // assignment
    unique_ptr& operator=(unique_ptr&& u) noexcept;
    unique_ptr& operator=(nullptr_t) noexcept;

    // 20.178.0.0.2, observers
    T& operator[](size_t i) const;
    pointer get() const noexcept;
    deleter_type& get_deleter() noexcept;
    const deleter_type& get_deleter() const noexcept;
    explicit operator bool() const noexcept;

    // 20.178.0.0.3 modifiers
    pointer release() noexcept;
    void reset(pointer p = pointer()) noexcept;
    void reset(nullptr_t) noexcept;
    template <class U> void reset(U) = delete;
    void swap(unique_ptr& u) noexcept;

    // disable copy from lvalue
    unique_ptr(const unique_ptr&) = delete;
    unique_ptr& operator=(const unique_ptr&) = delete;
  };
}
```

1 A specialization for array types is provided with a slightly altered interface.

(1.1) — Conversions between different types of `unique_ptr<T[], D>` or to or from the non-array forms of `unique_ptr` produce an ill-formed program.

(1.2) — Pointers to types derived from `T` are rejected by the constructors, and by `reset`.

(1.3) — The observers `operator*` and `operator->` are not provided.

(1.4) — The indexing observer `operator[]` is provided.

(1.5) — The default deleter will call `delete[]`.

2

Descriptions are provided below only for member functions that have behavior different from the primary template.

1 The template argument `T` shall be a complete type.

20.178.0.0.1 `unique_ptr` constructors [unique.ptr.runtime.ctor]

```
explicit unique_ptr(pointer p) noexcept;
unique_ptr(pointer p, see below d) noexcept;
unique_ptr(pointer p, see below d) noexcept;
```

These constructors behave the same as in the primary template except that they do not accept pointer types which are convertible to `pointer`. [*Note:* One implementation technique is to create private templated overloads of these members. — *end note*]

20.178.0.0.2 `unique_ptr` observers [unique.ptr.runtime.observers]

```
T& operator[](size_t i) const;
```

1 *Requires:* `i <` the number of elements in the array to which the stored pointer points.

2 *Returns:* `get()[i]`.

20.178.0.0.3 `unique_ptr` modifiers [unique.ptr.runtime.modifiers]

```
void reset(nullptr_t p) noexcept;
```

1 *Effects:* Equivalent to `reset(pointer())`.

20.178.0.1 `unique_ptr` creation [unique.ptr.create]

```
template <class T, class... Args> unique_ptr<T> make_unique(Args&&... args);
```

1

Remarks: This function shall not participate in overload resolution unless `T` is not an array.

1

Returns: `unique_ptr<T>(new T(std::forward<Args>(args)...))`.

```
template <class T> unique_ptr<T> make_unique(size_t n);
```

1

Remarks: This function shall not participate in overload resolution unless `T` is an array of unknown bound.

1

Returns: `unique_ptr<T>(new remove_extent_t<T>[n]())`.

```
template <class T, class... Args> unspecified  make_unique(Args&&...) = delete;
```

1

Remarks: This function shall not participate in overload resolution unless `T` is an array of known bound.

20.189.0.1 unique_ptr specialized algorithms [unique.ptr.special]

```
template <class T, class D> void swap(unique_ptr<T, D>& x, unique_ptr<T, D>& y) noexcept;
```

1 *Effects:* Calls `x.swap(y)`.

```
template <class T1, class D1, class T2, class D2>
  bool operator==(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

2 *Returns:* `x.get() == y.get()`.

```
template <class T1, class D1, class T2, class D2>
  bool operator!=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

3 *Returns:* `x.get() != y.get()`.

```
template <class T1, class D1, class T2, class D2>
  bool operator<(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

4 *Requires:* Let `CT` be `common_type<unique_ptr<T1, D1>::pointer, unique_ptr<T2, D2>::pointer>::type`. Then the specialization `less<CT>` shall be a function object type (20.283) that induces a strict weak ordering (25.98) on the pointer values.

5 *Returns:* `less<CT>()(x.get(), y.get())`.

6 *Remarks:* If `unique_ptr<T1, D1>::pointer` is not implicitly convertible to `CT` or `unique_ptr<T2, D2>::pointer` is not implicitly convertible to `CT`, the program is ill-formed.

```
template <class T1, class D1, class T2, class D2>
  bool operator<=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

7 *Returns:* `!(y < x)`.

```
template <class T1, class D1, class T2, class D2>
  bool operator>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

8 *Returns:* `y < x`.

```
template <class T1, class D1, class T2, class D2>
  bool operator>=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

9 *Returns:* `!(x < y)`.

```
template <class T, class D>
  bool operator==(const unique_ptr<T, D>& x, nullptr_t) noexcept;
template <class T, class D>
  bool operator==(nullptr_t, const unique_ptr<T, D>& x) noexcept;
```

10 *Returns:* `!x`.

```
template <class T, class D>
  bool operator!=(const unique_ptr<T, D>& x, nullptr_t) noexcept;
template <class T, class D>
  bool operator!=(nullptr_t, const unique_ptr<T, D>& x) noexcept;
```

11 *Returns:* `(bool)x`.

```
template <class T, class D>
  bool operator<(const unique_ptr<T, D>& x, nullptr_t);
template <class T, class D>
  bool operator<(nullptr_t, const unique_ptr<T, D>& x);
```

12 *Requires:* The specialization `less<unique_ptr<T, D>::pointer>` shall be a function object type (20.283) that induces a strict weak ordering (25.98) on the pointer values.

13 *Returns:* The first function template returns `less<unique_ptr<T, D>::pointer>()(x.get(), nullptr)`. The second function template returns `less<unique_ptr<T, D>::pointer>()(nullptr, x.get())`.

```
template <class T, class D>
  bool operator>(const unique_ptr<T, D>& x, nullptr_t);
template <class T, class D>
  bool operator>(nullptr_t, const unique_ptr<T, D>& x);
```

14 *Returns:* The first function template returns `nullptr < x`. The second function template returns `x < nullptr`.

```
template <class T, class D>
  bool operator<=(const unique_ptr<T, D>& x, nullptr_t);
template <class T, class D>
  bool operator<=(nullptr_t, const unique_ptr<T, D>& x);
```

15 *Returns:* The first function template returns `!(nullptr < x)`. The second function template returns `!(x < nullptr)`.

```
template <class T, class D>
  bool operator>=(const unique_ptr<T, D>& x, nullptr_t);
template <class T, class D>
  bool operator>=(nullptr_t, const unique_ptr<T, D>& x);
```

16 *Returns:* The first function template returns `!(x < nullptr)`. The second function template returns `!(nullptr < x)`.

20.189.1 Shared-ownership pointers [util.smartptr]

20.189.1.1 Class bad_weak_ptr [util.smartptr.weakptr]

```
namespace std {
  class bad_weak_ptr: public std::exception {
  public:
    bad_weak_ptr() noexcept;
  };
} // namespace std
```

1 An exception of type `bad_weak_ptr` is thrown by the `shared_ptr` constructor taking a `weak_ptr`.

```
bad_weak_ptr() noexcept;
```

2 *Postconditions:* `what()` returns `"bad_weak_ptr"`.

20.189.1.2 Class template shared_ptr [util.smartptr.shared]

1 The `shared_ptr` class template stores a pointer, usually obtained via `new`. `shared_ptr` implements semantics of shared ownership; the last remaining owner of the pointer is responsible for destroying the object, or otherwise releasing the resources associated with the stored pointer. A `shared_ptr` object is *empty* if it does not own a pointer.

```
namespace std {
  template<class T> class shared_ptr {
  public:
    typedef T element_type;
```

```
  // 20.201.0.0.1, constructors:
  constexpr shared_ptr() noexcept;
  template<class Y> explicit shared_ptr(Y* p);
  template<class Y, class D> shared_ptr(Y* p, D d);
  template<class Y, class D, class A> shared_ptr(Y* p, D d, A a);
  template <class D> shared_ptr(nullptr_t p, D d);
  template <class D, class A> shared_ptr(nullptr_t p, D d, A a);
  template<class Y> shared_ptr(const shared_ptr<Y>& r, T* p) noexcept;
  shared_ptr(const shared_ptr& r) noexcept;
  template<class Y> shared_ptr(const shared_ptr<Y>& r) noexcept;
  shared_ptr(shared_ptr&& r) noexcept;
  template<class Y> shared_ptr(shared_ptr<Y>&& r) noexcept;
  template<class Y> explicit shared_ptr(const weak_ptr<Y>& r);
  template<class Y> shared_ptr(auto_ptr<Y>&& r);
  template <class Y, class D> shared_ptr(unique_ptr<Y, D>&& r);
  constexpr shared_ptr(nullptr_t) : shared_ptr() { }

  // 20.229.0.0.1, destructor:
  ~shared_ptr();

  // 20.237.0.0.1, assignment:
  shared_ptr& operator=(const shared_ptr& r) noexcept;
  template<class Y> shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;
  shared_ptr& operator=(shared_ptr&& r) noexcept;
  template<class Y> shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;
  template<class Y> shared_ptr& operator=(auto_ptr<Y>&& r);
  template <class Y, class D> shared_ptr& operator=(unique_ptr<Y, D>&& r);

  // 20.241.0.0.1, modifiers:
  void swap(shared_ptr& r) noexcept;
  void reset() noexcept;
  template<class Y> void reset(Y* p);
  template<class Y, class D> void reset(Y* p, D d);
  template<class Y, class D, class A> void reset(Y* p, D d, A a);

  // 20.241.0.0.2, observers:
  T* get() const noexcept;
  T& operator*() const noexcept;
  T* operator->() const noexcept;
  long use_count() const noexcept;
  bool unique() const noexcept;
  explicit operator bool() const noexcept;
  template<class U> bool owner_before(shared_ptr<U> const& b) const;
  template<class U> bool owner_before(weak_ptr<U> const& b) const;
};

// 20.247.0.0.1, shared_ptr creation
template<class T, class... Args> shared_ptr<T> make_shared(Args&&... args);
template<class T, class A, class... Args>
  shared_ptr<T> allocate_shared(const A& a, Args&&... args);

// 20.262.0.0.1, shared_ptr comparisons:
template<class T, class U>
  bool operator==(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
```

```
  template<class T, class U>
    bool operator!=(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
  template<class T, class U>
    bool operator<(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
  template<class T, class U>
    bool operator>(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
  template<class T, class U>
    bool operator<=(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
  template<class T, class U>
    bool operator>=(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;

  template <class T>
    bool operator==(const shared_ptr<T>& a, nullptr_t) noexcept;
  template <class T>
    bool operator==(nullptr_t, const shared_ptr<T>& b) noexcept;
  template <class T>
    bool operator!=(const shared_ptr<T>& a, nullptr_t) noexcept;
  template <class T>
    bool operator!=(nullptr_t, const shared_ptr<T>& b) noexcept;
  template <class T>
    bool operator<(const shared_ptr<T>& a, nullptr_t) noexcept;
  template <class T>
    bool operator<(nullptr_t, const shared_ptr<T>& b) noexcept;
  template <class T>
    bool operator<=(const shared_ptr<T>& a, nullptr_t) noexcept;
  template <class T>
    bool operator<=(nullptr_t, const shared_ptr<T>& b) noexcept;
  template <class T>
    bool operator>(const shared_ptr<T>& a, nullptr_t) noexcept;
  template <class T>
    bool operator>(nullptr_t, const shared_ptr<T>& b) noexcept;
  template <class T>
    bool operator>=(const shared_ptr<T>& a, nullptr_t) noexcept;
  template <class T>
    bool operator>=(nullptr_t, const shared_ptr<T>& b) noexcept;

  // 20.262.0.0.2, shared_ptr specialized algorithms:
  template<class T> void swap(shared_ptr<T>& a, shared_ptr<T>& b) noexcept;

  // 20.262.0.0.3, shared_ptr casts:
  template<class T, class U>
    shared_ptr<T> static_pointer_cast(const shared_ptr<U>& r) noexcept;
  template<class T, class U>
    shared_ptr<T> dynamic_pointer_cast(const shared_ptr<U>& r) noexcept;
  template<class T, class U>
    shared_ptr<T> const_pointer_cast(const shared_ptr<U>& r) noexcept;

  // 20.263.0.0.1, shared_ptr get_deleter:
  template<class D, class T> D* get_deleter(const shared_ptr<T>& p) noexcept;

  // 20.264.0.0.1, shared_ptr I/O:
  template<class E, class T, class Y>
    basic_ostream<E, T>& operator<< (basic_ostream<E, T>& os, const shared_ptr<Y>& p);
} // namespace std
```

2

Specializations of `shared_ptr` shall be `CopyConstructible`, `CopyAssignable`, and `LessThanComparable`, allowing their use in standard containers. Specializations of `shared_ptr` shall be convertible to `bool`, allowing their use in boolean expressions and declarations in conditions. The template parameter `T` of `shared_ptr` may be an incomplete type.

1 [*Example:*

```
if(shared_ptr<X> px = dynamic_pointer_cast<X>(py)) {
  // do something with px
}
```

— *end example*]

2

For purposes of determining the presence of a data race, member functions shall access and modify only the `shared_ptr` and `weak_ptr` objects themselves and not objects they refer to. Changes in `use_count()` do not reflect modifications that can introduce data races.

20.201.0.0.1 `shared_ptr` constructors [util.smartptr.shared.const]

`constexpr shared_ptr() noexcept;`

1 *Effects:* Constructs an *empty* `shared_ptr` object.

2 *Postconditions:* `use_count() == 0 && get() == nullptr`.

`template<class Y> explicit shared_ptr(Y* p);`

3 *Requires:* `p` shall be convertible to `T*`. `Y` shall be a complete type. The expression `delete p` shall be well formed, shall have well defined behavior, and shall not throw exceptions.

1 *Effects:* Constructs a `shared_ptr` object that *owns* the pointer `p`.

2 *Postconditions:* `use_count() == 1 && get() == p`.

3 *Throws:* `bad_alloc`, or an implementation-defined exception when a resource other than memory could not be obtained.

1 *Exception safety:* If an exception is thrown, `delete p` is called.

```
template<class Y, class D> shared_ptr(Y* p, D d);
template<class Y, class D, class A> shared_ptr(Y* p, D d, A a);
template <class D> shared_ptr(nullptr_t p, D d);
template <class D, class A> shared_ptr(nullptr_t p, D d, A a);
```

1 *Requires:* `p` shall be convertible to `T*`. `D` shall be `CopyConstructible`. The copy constructor and destructor of `D` shall not throw exceptions. The expression `d(p)` shall be well formed, shall have well defined behavior, and shall not throw exceptions. `A` shall be an allocator (17.165.0.1). The copy constructor and destructor of `A` shall not throw exceptions.

1 *Effects:* Constructs a `shared_ptr` object that *owns* the object `p` and the deleter `d`. The second and fourth constructors shall use a copy of `a` to allocate memory for internal use.

1 *Postconditions:* `use_count() == 1 && get() == p`.

2 *Throws:* `bad_alloc`, or an implementation-defined exception when a resource other than memory could not be obtained.

3 *Exception safety:* If an exception is thrown, `d(p)` is called.

`template<class Y> shared_ptr(const shared_ptr<Y>& r, T* p) noexcept;`

1

Effects: Constructs a `shared_ptr` instance that stores `p` and *shares ownership* with `r`.

1 *Postconditions:* `get() == p && use_count() == r.use_count()`

2

[*Note:* To avoid the possibility of a dangling pointer, the user of this constructor must ensure that `p` remains valid at least until the ownership group of `r` is destroyed. — *end note*]

1

[*Note:* This constructor allows creation of an *empty* `shared_ptr` instance with a non-null stored pointer. — *end note*]

```
shared_ptr(const shared_ptr& r) noexcept;
template<class Y> shared_ptr(const shared_ptr<Y>& r) noexcept;
```

1 *Remark:* The second constructor shall not participate in overload resolution unless `Y*` is implicitly convertible to `T*`.

1 *Effects:* If `r` is *empty*, constructs an *empty* `shared_ptr` object; otherwise, constructs a `shared_ptr` object that *shares ownership* with `r`.

1 *Postconditions:* `get() == r.get() && use_count() == r.use_count()`.

```
shared_ptr(shared_ptr&& r) noexcept;
template<class Y> shared_ptr(shared_ptr<Y>&& r) noexcept;
```

1 *Remark:* The second constructor shall not participate in overload resolution unless `Y*` is convertible to `T*`.

2 *Effects:* Move-constructs a `shared_ptr` instance from `r`.

3

Postconditions: `*this` shall contain the old value of `r`. `r` shall be *empty*. `r.get() == nullptr`.

```
template<class Y> explicit shared_ptr(const weak_ptr<Y>& r);
```

1 *Requires:* `Y*` shall be convertible to `T*`.

2 *Effects:* Constructs a `shared_ptr` object that *shares ownership* with `r` and stores a copy of the pointer stored in `r`.

3 *Postconditions:* `use_count() == r.use_count()`.

4 *Throws:* `bad_weak_ptr` when `r.expired()`.

5 *Exception safety:* If an exception is thrown, the constructor has no effect.

```
template<class Y> shared_ptr(auto_ptr<Y>&& r);
```

6 *Requires:* `r.release()` shall be convertible to `T*`. `Y` shall be a complete type. The expression `delete r.release()` shall be well formed, shall have well defined behavior, and shall not throw exceptions.

7 *Effects:* Constructs a `shared_ptr` object that stores and *owns* `r.release()`.

8 *Postconditions:* `use_count() == 1 && r.get() == nullptr`.

9 *Throws:* `bad_alloc`, or an implementation-defined exception when a resource other than memory could not be obtained.

10 *Exception safety:* If an exception is thrown, the constructor has no effect.

```
template <class Y, class D> shared_ptr(unique_ptr<Y, D>&& r);
```

11 *Effects:* Equivalent to `shared_ptr(r.release(), r.get_deleter())` when `D` is not a reference type, otherwise `shared_ptr(r.release(), ref(r.get_deleter()))`.

12 *Exception safety:* If an exception is thrown, the constructor has no effect.

20.229.0.0.1 `shared_ptr` destructor [util.smartptr.shared.dest]

```
~shared_ptr();
```

1 *Effects:*

— If `*this` is *empty* or shares ownership with another `shared_ptr` instance (`use_count() > 1`), there are no side effects.

— Otherwise, if `*this` *owns* an object `p` and a deleter `d`, `d(p)` is called.

— Otherwise, `*this` *owns* a pointer `p`, and `delete p` is called.

1

[*Note:* Since the destruction of `*this` decreases the number of instances that share ownership with `*this` by one, after `*this` has been destroyed all `shared_ptr` instances that shared ownership with `*this` will report a `use_count()` that is one less than its previous value. — *end note*]

20.237.0.0.1 `shared_ptr` assignment [util.smartptr.shared.assign]

```
shared_ptr& operator=(const shared_ptr& r) noexcept;
template<class Y> shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;
template<class Y> shared_ptr& operator=(auto_ptr<Y>&& r);
```

1 *Effects:* Equivalent to `shared_ptr(r).swap(*this)`.

2 *Returns:* `*this`.

3 [*Note:* The use count updates caused by the temporary object construction and destruction are not observable side effects, so the implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary. In particular, in the example:

```
shared_ptr<int> p(new int);
shared_ptr<void> q(p);
p = p;
q = p;
```

both assignments may be no-ops. — *end note*]

```
shared_ptr& operator=(shared_ptr&& r) noexcept;
template<class Y> shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;
```

1 *Effects:* Equivalent to `shared_ptr(std::move(r)).swap(*this)`.

2

Returns: `*this`.

```
template <class Y, class D> shared_ptr& operator=(unique_ptr<Y, D>&& r);
```

1 *Effects:* Equivalent to `shared_ptr(std::move(r)).swap(*this)`.

2 *Returns:* `*this`

20.241.0.0.1 shared_ptr modifiers [util.smartptr.shared.mod]

```
void swap(shared_ptr& r) noexcept;
```

1 *Effects:* Exchanges the contents of `*this` and `r`.

```
void reset() noexcept;
```

2 *Effects:* Equivalent to `shared_ptr().swap(*this)`.

```
template<class Y> void reset(Y* p);
```

3 *Effects:* Equivalent to `shared_ptr(p).swap(*this)`.

```
template<class Y, class D> void reset(Y* p, D d);
```

4 *Effects:* Equivalent to `shared_ptr(p, d).swap(*this)`.

```
template<class Y, class D, class A> void reset(Y* p, D d, A a);
```

5 *Effects:* Equivalent to `shared_ptr(p, d, a).swap(*this)`.

20.241.0.0.2 shared_ptr observers [util.smartptr.shared.obs]

```
T* get() const noexcept;
```

1 *Returns:* the stored pointer.

```
T& operator*() const noexcept;
```

2 *Requires:* `get() != 0`.

3 *Returns:* `*get()`.

4 *Remarks:* When `T` is `void`, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well formed.

```
T* operator->() const noexcept;
```

5 *Requires:* `get() != 0`.

6 *Returns:* `get()`.

```
long use_count() const noexcept;
```

1 *Returns:* the number of `shared_ptr` objects, `*this` included, that *share ownership* with `*this`, or `0` when `*this` is *empty*.

1 [*Note:* `use_count()` is not necessarily efficient. — *end note*]

```
bool unique() const noexcept;
```

2 *Returns:* `use_count() == 1`.

3 [*Note:* `unique()` may be faster than `use_count()`. If you are using `unique()` to implement copy on write, do not rely on a specific value when `get() == nullptr`. — *end note*]

```
explicit operator bool() const noexcept;
```

1 *Returns:* `get() != 0`.

```
template<class U> bool owner_before(shared_ptr<U> const& b) const;
template<class U> bool owner_before(weak_ptr<U> const& b) const;
```

2 *Returns:* An unspecified value such that

(2.1) — `x.owner_before(y)` defines a strict weak ordering as defined in 25.98;

(2.2) — under the equivalence relation defined by `owner_before`, `!a.owner_before(b) && !b.owner_before(a)`, two `shared_ptr` or `weak_ptr` instances are equivalent if and only if they share ownership or are both empty.

20.247.0.0.1 `shared_ptr` creation [util.smartptr.shared.create]

```
template<class T, class... Args> shared_ptr<T> make_shared(Args&&... args);
template<class T, class A, class... Args>
  shared_ptr<T> allocate_shared(const A& a, Args&&... args);
```

1

Requires: The expression `::new (pv) T(std::forward<Args>(args)...)`, where `pv` has type `void*` and points to storage suitable to hold an object of type `T`, shall be well formed. `A` shall be an *allocator* (17.165.0.1). The copy constructor and destructor of `A` shall not throw exceptions.

1

Effects: Allocates memory suitable for an object of type `T` and constructs an object in that memory via the placement new expression `::new (pv) T(std::forward<Args>(args)...)`. The template `allocate_shared` uses a copy of `a` to allocate memory. If an exception is thrown, the functions have no effect.

1 *Returns:* A `shared_ptr` instance that stores and owns the address of the newly constructed object of type `T`.

2 *Postconditions:* `get() != 0 && use_count() == 1`

3 *Throws:* `bad_alloc`, or an exception thrown from `A::allocate` or from the constructor of `T`.

4

Remarks: Implementations should perform no more than one memory allocation. [*Note:* This provides efficiency equivalent to an intrusive smart pointer. — *end note*]

1

[*Note:* These functions will typically allocate more memory than `sizeof(T)` to allow for internal bookkeeping structures such as the reference counts. — *end note*]

20.262.0.0.1 `shared_ptr` comparison [util.smartptr.shared.cmp]

```
template<class T, class U> bool operator==(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
```

1 *Returns:* `a.get() == b.get()`.

```
template<class T, class U> bool operator<(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
```

2 *Returns:* `less<V>()(a.get(), b.get())`, where `V` is the composite pointer type (Clause 5) of `T*` and `U*`.

3 [*Note:* Defining a comparison operator allows `shared_ptr` objects to be used as keys in associative containers. — *end note*]

```
template <class T>
  bool operator==(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator==(nullptr_t, const shared_ptr<T>& a) noexcept;
```

4 *Returns:* `!a`.

```
template <class T>
  bool operator!=(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator!=(nullptr_t, const shared_ptr<T>& a) noexcept;
```

5 *Returns:* `(bool)a`.

```
template <class T>
  bool operator<(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator<(nullptr_t, const shared_ptr<T>& a) noexcept;
```

6 *Returns:* The first function template returns `less<T*>()(a.get(), nullptr)`. The second function template returns `less<T*>()(nullptr, a.get())`.

```
template <class T>
  bool operator>(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator>(nullptr_t, const shared_ptr<T>& a) noexcept;
```

7 *Returns:* The first function template returns `nullptr < a`. The second function template returns `a < nullptr`.

```
template <class T>
  bool operator<=(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator<=(nullptr_t, const shared_ptr<T>& a) noexcept;
```

8 *Returns:* The first function template returns `!(nullptr < a)`. The second function template returns `!(a < nullptr)`.

```
template <class T>
  bool operator>=(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator>=(nullptr_t, const shared_ptr<T>& a) noexcept;
```

9 *Returns:* The first function template returns `!(a < nullptr)`. The second function template returns `!(nullptr < a)`.

20.262.0.0.2 `shared_ptr` specialized algorithms [util.smartptr.shared.spec]

```
template<class T> void swap(shared_ptr<T>& a, shared_ptr<T>& b) noexcept;
```

1 *Effects:* Equivalent to `a.swap(b)`.

20.262.0.0.3 `shared_ptr` casts [util.smartptr.shared.cast]

```
template<class T, class U> shared_ptr<T> static_pointer_cast(const shared_ptr<U>& r) noexcept;
```

1 *Requires:* The expression `static_cast<T*>(r.get())` shall be well formed.

2 *Returns:* If `r` is *empty*, an *empty* `shared_ptr<T>`; otherwise, a `shared_ptr<T>` object that stores `static_cast<T*>(r.get())` and *shares ownership* with `r`.

3 *Postconditions:* `w.get() == static_cast<T*>(r.get())` and `w.use_count() == r.use_count()`, where `w` is the return value.

4

[*Note:* The seemingly equivalent expression `shared_ptr<T>(static_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. — *end note*]

```
template<class T, class U> shared_ptr<T> dynamic_pointer_cast(const shared_ptr<U>& r) noexcept;
```

1 *Requires:* The expression `dynamic_cast<T*>(r.get())` shall be well formed and shall have well defined behavior.

2 *Returns:*

(2.1) — When `dynamic_cast<T*>(r.get())` returns a nonzero value, a `shared_ptr<T>` object that stores a copy of it and *shares ownership* with `r`;

(2.2) — Otherwise, an *empty* `shared_ptr<T>` object.

3 *Postcondition:* `w.get() == dynamic_cast<T*>(r.get())`, where `w` is the return value.

4 [*Note:* The seemingly equivalent expression `shared_ptr<T>(dynamic_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. — *end note*]

```
template<class T, class U> shared_ptr<T> const_pointer_cast(const shared_ptr<U>& r) noexcept;
```

5 *Requires:* The expression `const_cast<T*>(r.get())` shall be well formed.

6 *Returns:* If `r` is empty, an empty `shared_ptr<T>`; otherwise, a `shared_ptr<T>` object that stores `const_cast<T*>(r.get())` and shares ownership with `r`.

7 *Postconditions:* `w.get() == const_cast<T*>(r.get())` and `w.use_count() == r.use_count()`, where `w` is the return value.

8 [*Note:* The seemingly equivalent expression `shared_ptr<T>(const_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. — *end note*]

20.263.0.0.1 get_deleter [util.smartptr.getdeleter]

```
template<class D, class T> D* get_deleter(const shared_ptr<T>& p) noexcept;
```

1 *Returns:* If `p` *owns* a deleter `d` of type cv-unqualified `D`, returns `&d`; otherwise returns `nullptr`. The returned pointer remains valid as long as there exists a `shared_ptr` instance that owns `d`. [*Note:* It is unspecified whether the pointer remains valid longer than that. This can happen if the implementation doesn't destroy the deleter until all `weak_ptr` instances that share ownership with `p` have been destroyed. — *end note*]

20.264.0.0.1 shared_ptr I/O [util.smartptr.shared.io]

```
template<class E, class T, class Y>
  basic_ostream<E, T>& operator<< (basic_ostream<E, T>& os, shared_ptr<Y> const& p);
```

1 *Effects:* `os << p.get();`.

2 *Returns:* `os`.

20.264.0.1 Class template weak_ptr [util.smartptr.weak]

1 The `weak_ptr` class template stores a weak reference to an object that is already managed by a `shared_ptr`. To access the object, a `weak_ptr` can be converted to a `shared_ptr` using the member function `lock`.

```
namespace std {
  template<class T> class weak_ptr {
  public:
    typedef T element_type;

    // 20.264.0.1.1, constructors
    constexpr weak_ptr() noexcept;
    template<class Y> weak_ptr(shared_ptr<Y> const& r) noexcept;
    weak_ptr(weak_ptr const& r) noexcept;
```

```
    template<class Y> weak_ptr(weak_ptr<Y> const& r) noexcept;
    weak_ptr(weak_ptr&& r) noexcept;
    template<class Y> weak_ptr(weak_ptr<Y>&& r) noexcept;

    // 20.264.0.1.2, destructor
    ~weak_ptr();

    // 20.264.0.1.3, assignment
    weak_ptr& operator=(weak_ptr const& r) noexcept;
    template<class Y> weak_ptr& operator=(weak_ptr<Y> const& r) noexcept;
    template<class Y> weak_ptr& operator=(shared_ptr<Y> const& r) noexcept;
    weak_ptr& operator=(weak_ptr&& r) noexcept;
    template<class Y> weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;

    // 20.264.0.1.4, modifiers
    void swap(weak_ptr& r) noexcept;
    void reset() noexcept;

    // 20.264.0.1.5, observers
    long use_count() const noexcept;
    bool expired() const noexcept;
    shared_ptr<T> lock() const noexcept;
    template<class U> bool owner_before(shared_ptr<U> const& b) const;
    template<class U> bool owner_before(weak_ptr<U> const& b) const;
  };

  // 20.266.0.0.1, specialized algorithms
  template<class T> void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;
} // namespace std
```

2 Specializations of `weak_ptr` shall be `CopyConstructible` and `CopyAssignable`, allowing their use in standard containers. The template parameter `T` of `weak_ptr` may be an incomplete type.

20.264.0.1.1 `weak_ptr` constructors [util.smartptr.weak.const]

```
constexpr weak_ptr() noexcept;
```

1 *Effects:* Constructs an *empty* `weak_ptr` object.

2 *Postconditions:* `use_count() == 0`.

```
weak_ptr(const weak_ptr& r) noexcept;
template<class Y> weak_ptr(const weak_ptr<Y>& r) noexcept;
template<class Y> weak_ptr(const shared_ptr<Y>& r) noexcept;
```

3 *Remark:* The second and third constructors shall not participate in overload resolution unless `Y*` is implicitly convertible to `T*`.

4 *Effects:* If `r` is *empty*, constructs an *empty* `weak_ptr` object; otherwise, constructs a `weak_ptr` object that *shares ownership* with `r` and stores a copy of the pointer stored in `r`.

5 *Postconditions:* `use_count() == r.use_count()`.

```
weak_ptr(weak_ptr&& r) noexcept;
template<class Y> weak_ptr(weak_ptr<Y>&& r) noexcept;
```

6 *Remark:* The second constructor shall not participate in overload resolution unless `Y*` is implicitly convertible to `T*`.

7 *Effects:* Move-constructs a `weak_ptr` instance from `r`.

8 *Postconditions:* `*this` shall contain the old value of `r`. `r` shall be *empty*. `r.use_count() == 0`.

20.264.0.1.2 `weak_ptr` destructor [util.smartptr.weak.dest]

```
~weak_ptr();
```

1 *Effects:* Destroys this `weak_ptr` object but has no effect on the object its stored pointer points to.

20.264.0.1.3 `weak_ptr` assignment [util.smartptr.weak.assign]

```
weak_ptr& operator=(const weak_ptr& r) noexcept;
template<class Y> weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
template<class Y> weak_ptr& operator=(const shared_ptr<Y>& r) noexcept;
```

1 *Effects:* Equivalent to `weak_ptr(r).swap(*this)`.

2 *Remarks:* The implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary.

3 *Returns:* `*this`.

```
weak_ptr& operator=(weak_ptr&& r) noexcept;
template<class Y> weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;
```

4 *Effects:* Equivalent to `weak_ptr(std::move(r)).swap(*this)`.

5 *Returns:* `*this`.

20.264.0.1.4 `weak_ptr` modifiers [util.smartptr.weak.mod]

```
void swap(weak_ptr& r) noexcept;
```

1 *Effects:* Exchanges the contents of `*this` and `r`.

```
void reset() noexcept;
```

2 *Effects:* Equivalent to `weak_ptr().swap(*this)`.

20.264.0.1.5 `weak_ptr` observers [util.smartptr.weak.obs]

```
long use_count() const noexcept;
```

1 *Returns:* `0` if `*this` is *empty*; otherwise, the number of `shared_ptr` instances that *share ownership* with `*this`.

2 [*Note:* `use_count()` is not necessarily efficient. — *end note*]

```
bool expired() const noexcept;
```

1 *Returns:* `use_count() == 0`.

2 [*Note:* `expired()` may be faster than `use_count()`. — *end note*]

```
shared_ptr<T> lock() const noexcept;
```

3 *Returns:* `expired() ? shared_ptr<T>() : shared_ptr<T>(*this)`, executed atomically.

```
template<class U> bool owner_before(shared_ptr<U> const& b) const;
template<class U> bool owner_before(weak_ptr<U> const& b) const;
```

1 *Returns:* An unspecified value such that

(1.1) — `x.owner_before(y)` defines a strict weak ordering as defined in 25.98;

(1.2) — under the equivalence relation defined by `owner_before`, `!a.owner_before(b) && !b.owner_before(a)`, two `shared_ptr` or `weak_ptr` instances are equivalent if and only if they share ownership or are both empty.

20.266.0.0.1 `weak_ptr` specialized algorithms [util.smartptr.weak.spec]

```
template<class T> void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;
```

1 *Effects:* Equivalent to `a.swap(b)`.

20.266.0.1 Class template `owner_less` [util.smartptr.ownerless]

1 The class template `owner_less` allows ownership-based mixed comparisons of shared and weak pointers.

```
namespace std {
  template<class T> struct owner_less;

  template<class T> struct owner_less<shared_ptr<T> > {
    typedef bool result_type;
    typedef shared_ptr<T> first_argument_type;
    typedef shared_ptr<T> second_argument_type;
    bool operator()(shared_ptr<T> const&, shared_ptr<T> const&) const;
    bool operator()(shared_ptr<T> const&, weak_ptr<T> const&) const;
    bool operator()(weak_ptr<T> const&, shared_ptr<T> const&) const;
  };

  template<class T> struct owner_less<weak_ptr<T> > {
    typedef bool result_type;
    typedef weak_ptr<T> first_argument_type;
    typedef weak_ptr<T> second_argument_type;
    bool operator()(weak_ptr<T> const&, weak_ptr<T> const&) const;
    bool operator()(shared_ptr<T> const&, weak_ptr<T> const&) const;
    bool operator()(weak_ptr<T> const&, shared_ptr<T> const&) const;
  };
}
```

2 `operator()(x,y)` shall return `x.owner_before(y)`. [*Note:* Note that

(2.1) — `operator()` defines a strict weak ordering as defined in 25.98;

(2.2) — under the equivalence relation defined by `operator()`, `!operator()(a, b) && !operator()(b, a)`, two `shared_ptr` or `weak_ptr` instances are equivalent if and only if they share ownership or are both empty.

— *end note*]

20.266.0.2 Class template `enable_shared_from_this` [util.smartptr.enab]

1

A class `T` can inherit from `enable_shared_from_this<T>` to inherit the `shared_from_this` member functions that obtain a *shared_ptr* instance pointing to `*this`.

1 [*Example:*

```
struct X: public enable_shared_from_this<X> {
};

int main() {
  shared_ptr<X> p(new X);
  shared_ptr<X> q = p->shared_from_this();
  assert(p == q);
  assert(!(p < q ) && !(q < p)); // p and q share ownership
}
```

— *end example*]

```
namespace std {
  template<class T> class enable_shared_from_this {
  protected:
    constexpr enable_shared_from_this() noexcept;
    enable_shared_from_this(enable_shared_from_this const&) noexcept;
    enable_shared_from_this& operator=(enable_shared_from_this const&) noexcept;
    ~enable_shared_from_this();
  public:
    shared_ptr<T> shared_from_this();
    shared_ptr<T const> shared_from_this() const;
  };
} // namespace std
```

2 The template parameter `T` of `enable_shared_from_this` may be an incomplete type.

```
constexpr enable_shared_from_this() noexcept;
enable_shared_from_this(const enable_shared_from_this<T>&) noexcept;
```

3 *Effects:* Constructs an `enable_shared_from_this<T>` object.

```
enable_shared_from_this<T>& operator=(const enable_shared_from_this<T>&) noexcept;
```

4 *Returns:* `*this`.

```
~enable_shared_from_this();
```

5 *Effects:* Destroys `*this`.

```
shared_ptr<T>       shared_from_this();
shared_ptr<T const> shared_from_this() const;
```

1 *Requires:* `enable_shared_from_this<T>` shall be an accessible base class of `T`. `*this` shall be a subobject of an object `t` of type `T`. There shall be at least one `shared_ptr` instance `p` that *owns* `&t`.

1 *Returns:* A `shared_ptr<T>` object `r` that *shares ownership with* `p`.

2 *Postconditions:* `r.get() == this`.

3 [*Note:* A possible implementation is shown below:

```
template<class T> class enable_shared_from_this {
private:
  weak_ptr<T> __weak_this;
protected:
  constexpr enable_shared_from_this() : __weak_this() { }
  enable_shared_from_this(enable_shared_from_this const &) { }
  enable_shared_from_this& operator=(enable_shared_from_this const &) { return *this; }
  ~enable_shared_from_this() { }
public:
  shared_ptr<T> shared_from_this() { return shared_ptr<T>(__weak_this); }
  shared_ptr<T const> shared_from_this() const { return shared_ptr<T const>(__weak_this); }
};
```

4

The `shared_ptr` constructors that create unique pointers can detect the presence of an `enable_shared_from_this` base and assign the newly created `shared_ptr` to its `__weak_this` member. — *end note*]

20.279.0.1 shared_ptr atomic access [util.smartptr.shared.atomic]

1

Concurrent access to a `shared_ptr` object from multiple threads does not introduce a data race if the access is done exclusively via the functions in this section and the instance is passed as their first argument.

1 The meaning of the arguments of type `memory_order` is explained in 29.3.

```
template<class T>
  bool atomic_is_lock_free(const shared_ptr<T>* p);
```

2 *Requires:* `p` shall not be null.

3 *Returns:* `true` if atomic access to `*p` is lock-free, `false` otherwise.

4 *Throws:* Nothing.

```
template<class T>
  shared_ptr<T> atomic_load(const shared_ptr<T>* p);
```

5 *Requires:* `p` shall not be null.

6 *Returns:* `atomic_load_explicit(p, memory_order_seq_cst)`.

7 *Throws:* Nothing.

```
template<class T>
  shared_ptr<T> atomic_load_explicit(const shared_ptr<T>* p, memory_order mo);
```

8 *Requires:* `p` shall not be null.

9 *Requires:* `mo` shall not be `memory_order_release` or `memory_order_acq_rel`.

10 *Returns:* `*p`.

11 *Throws:* Nothing.

```
template<class T>
  void atomic_store(shared_ptr<T>* p, shared_ptr<T> r);
```

12 *Requires:* `p` shall not be null.

13 *Effects:* `atomic_store_explicit(p, r, memory_order_seq_cst)`.

14 *Throws:* Nothing.

```
template<class T>
  void atomic_store_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);
```

15 *Requires:* `p` shall not be null.

16 *Requires:* `mo` shall not be `memory_order_acquire` or `memory_order_acq_rel`.

17 *Effects:* `p->swap(r)`.

18 *Throws:* Nothing.

```
template<class T>
  shared_ptr<T> atomic_exchange(shared_ptr<T>* p, shared_ptr<T> r);
```

19 *Requires:* `p` shall not be null.

20 *Returns:* `atomic_exchange_explicit(p, r, memory_order_seq_cst)`.

21 *Throws:* Nothing.

```
template<class T>
  shared_ptr<T> atomic_exchange_explicit(shared_ptr<T>* p, shared_ptr<T> r,
                                         memory_order mo);
```

22 *Requires:* `p` shall not be null.

23 *Effects:* `p->swap(r)`.

24 *Returns:* The previous value of `*p`.

25 *Throws:* Nothing.

```
template<class T>
  bool atomic_compare_exchange_weak(
    shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);
```

26 *Requires:* `p` shall not be null and `v` shall not be null.

27 *Returns:* `atomic_compare_exchange_weak_explicit(p, v, w, memory_order_seq_cst, memory_order_seq_cst)`.

28 *Throws:* Nothing.

```
template<class T>
  bool atomic_compare_exchange_strong(
    shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);
```

29 *Returns:* `atomic_compare_exchange_strong_explicit(p, v, w, memory_order_seq_cst, memory_order_seq_cst)`.

```
template<class T>
  bool atomic_compare_exchange_weak_explicit(
    shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
    memory_order success, memory_order failure);
template<class T>
  bool atomic_compare_exchange_strong_explicit(
    shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
    memory_order success, memory_order failure);
```

30 *Requires:* `p` shall not be null and `v` shall not be null.

31 *Requires:* `failure` shall not be `memory_order_release`, `memory_order_acq_rel`, or stronger than `success`.

32 *Effects:* If `*p` is equivalent to `*v`, assigns `w` to `*p` and has synchronization semantics corresponding to the value of `success`, otherwise assigns `*p` to `*v` and has synchronization semantics corresponding to the value of `failure`.

33 *Returns:* `true` if `*p` was equivalent to `*v`, `false` otherwise.

1 *Throws:* Nothing.

2 *Remarks:* two `shared_ptr` objects are equivalent if they store the same pointer value and share ownership.

3 *Remarks:* the weak forms may fail spuriously. See 29.50.

20.282.0.1 Smart pointer hash support [util.smartptr.hash]

```
template <class T, class D> struct hash<unique_ptr<T, D> >;
```

1 The template specialization shall meet the requirements of class template `hash` (20.443.1). For an object `p` of type `UP`, where `UP` is `unique_ptr<T, D>`, `hash<UP>()(p)` shall evaluate to the same value as `hash<typename UP::pointer>()(p.get())`.

2 *Requires:* The specialization `hash<typename UP::pointer>` shall be well-formed and well-defined, and shall meet the requirements of class template `hash` (20.443.1).

```
template <class T> struct hash<shared_ptr<T> >;
```

3 The template specialization shall meet the requirements of class template `hash` (20.443.1). For an object `p` of type `shared_ptr<T>`, `hash<shared_ptr<T> >()(p)` shall evaluate to the same value as `hash<T*>()(p.get())`.

20.283 Function objects [function.objects]

1

A *function object type* is an object type (3.2955) that can be the type of the *postfix-expression* in a function call (5.955.1, 13.230.0.1).[230] A *function object* is an object of a function object type. In the places where one would expect to pass a pointer to a function to an algorithmic template (Clause 25), the interface is specified to accept a function object. This not only makes algorithmic templates work with pointers to functions, but also enables them to work with arbitrary function objects.

1 **Header `<functional>` synopsis**

```
namespace std {
  // D.57.1, base (deprecated):
  template <class Arg, class Result> struct unary_function;
  template <class Arg1, class Arg2, class Result> struct binary_function;

  // 20.339.1, reference_wrapper:
  template <class T> class reference_wrapper;

  template <class T> reference_wrapper<T> ref(T&) noexcept;
  template <class T> reference_wrapper<const T> cref(const T&) noexcept;
  template <class T> void ref(const T&&) = delete;
  template <class T> void cref(const T&&) = delete;

  template <class T> reference_wrapper<T> ref(reference_wrapper<T>) noexcept;
  template <class T> reference_wrapper<const T> cref(reference_wrapper<T>) noexcept;

  // 20.339.2, arithmetic operations:
  template <class T = void> struct plus;
  template <class T = void> struct minus;
  template <class T = void> struct multiplies;
  template <class T = void> struct divides;
  template <class T = void> struct modulus;
  template <class T = void> struct negate;
  template <> struct plus<void>;
  template <> struct minus<void>;
  template <> struct multiplies<void>;
  template <> struct divides<void>;
```

230) Such a type is a function pointer or a class type which has a member `operator()` or a class type which has a conversion to a pointer to function.

```
template <> struct modulus<void>;
template <> struct negate<void>;

// 20.339.3, comparisons:
template <class T = void> struct equal_to;
template <class T = void> struct not_equal_to;
template <class T = void> struct greater;
template <class T = void> struct less;
template <class T = void> struct greater_equal;
template <class T = void> struct less_equal;
template <> struct equal_to<void>;
template <> struct not_equal_to<void>;
template <> struct greater<void>;
template <> struct less<void>;
template <> struct greater_equal<void>;
template <> struct less_equal<void>;

// 20.357.1, logical operations:
template <class T = void> struct logical_and;
template <class T = void> struct logical_or;
template <class T = void> struct logical_not;
template <> struct logical_and<void>;
template <> struct logical_or<void>;
template <> struct logical_not<void>;

// 20.357.2, bitwise operations:
template <class T = void> struct bit_and;
template <class T = void> struct bit_or;
template <class T = void> struct bit_xor;
template <class T = void> struct bit_not;
template <> struct bit_and<void>;
template <> struct bit_or<void>;
template <> struct bit_xor<void>;
template <> struct bit_not<void>;

// 20.357.3, negators:
template <class Predicate> class unary_negate;
template <class Predicate>
  constexpr unary_negate<Predicate> not1(const Predicate&);
template <class Predicate> class binary_negate;
template <class Predicate>
  constexpr binary_negate<Predicate> not2(const Predicate&);

// 20.357.4, bind:
template<class T> struct is_bind_expression;
template<class T> struct is_placeholder;

template<class F, class... BoundArgs>
  unspecified  bind(F&&, BoundArgs&&...);
template<class R, class F, class... BoundArgs>
  unspecified  bind(F&&, BoundArgs&&...);

namespace placeholders {
  // M is the implementation-defined number of placeholders
  extern unspecified  _1;
```

```
  extern unspecified  _2;
              .
              .
              .
  extern unspecified  _M;
}

// D.58, binders (deprecated):
template <class Fn> class binder1st;
template <class Fn, class T>
  binder1st<Fn> bind1st(const Fn&, const T&);
template <class Fn> class binder2nd;
template <class Fn, class T>
  binder2nd<Fn> bind2nd(const Fn&, const T&);

// D.57.2.1, adaptors (deprecated):
template <class Arg, class Result> class pointer_to_unary_function;
template <class Arg, class Result>
  pointer_to_unary_function<Arg,Result> ptr_fun(Result (*)(Arg));
template <class Arg1, class Arg2, class Result>
  class pointer_to_binary_function;
template <class Arg1, class Arg2, class Result>
  pointer_to_binary_function<Arg1,Arg2,Result>
    ptr_fun(Result (*)(Arg1,Arg2));

// D.57.2.2, adaptors (deprecated):

    bool operator!=(const function<R(ArgTypes...)>&, nullptr_t);
  template<class R, class... ArgTypes>
    bool operator!=(nullptr_t, const function<R(ArgTypes...)>&);

  // 20.443.1, hash function primary template:
  template <class T> struct hash;

  // Hash function specializations
  template <> struct hash<bool>;
  template <> struct hash<char>;
  template <> struct hash<signed char>;
  template <> struct hash<unsigned char>;
  template <> struct hash<char16_t>;
  template <> struct hash<char32_t>;
  template <> struct hash<wchar_t>;
  template <> struct hash<short>;
  template <> struct hash<unsigned short>;
  template <> struct hash<int>;
  template <> struct hash<unsigned int>;
  template <> struct hash<long>;
  template <> struct hash<long long>;
  template <> struct hash<unsigned long>;
  template <> struct hash<unsigned long long>;

  template <> struct hash<float>;
  template <> struct hash<double>;
  template <> struct hash<long double>;

  template<class T> struct hash<T*>;
}
```

2 [*Example:* If a C++ program wants to have a by-element addition of two vectors `a` and `b` containing `double` and put the result into `a`, it can do:

```
transform(a.begin(), a.end(), b.begin(), a.begin(), plus<double>());
```

— *end example*]

3 [*Example:* To negate every element of `a`:

```
transform(a.begin(), a.end(), a.begin(), negate<double>());
```

— *end example*]

4 [*Note:* To enable adaptors and other components to manipulate function objects that take one or two arguments many of the function objects in this clause correspondingly provide typedefs `argument_type` and `result_type` for function objects that take one argument and `first_argument_type`, `second_argument_type`, and `result_type` for function objects that take two arguments. — *end note*]

20.291.1 Definitions [func.def]

1 The following definitions apply to this Clause:

2 A *call signature* is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.

1 A *callable type* is a function object type (20.283) or a pointer to member.

1 A *callable object* is an object of a callable type.

2 A *call wrapper type* is a type that holds a callable object and supports a call operation that forwards to that object.

1 A *call wrapper* is an object of a call wrapper type.

1 A *target object* is the callable object held by a call wrapper.

20.295.1 Requirements [func.require]

1 Define *INVOKE*`(f, t1, t2, ..., tN)` as follows:

— `(t1.*f)(t2, ..., tN)` when `f` is a pointer to a member function of a class `T` and `t1` is an object of type `T` or a reference to an object of type `T` or a reference to an object of a type derived from `T`;

— `((*t1).*f)(t2, ..., tN)` when `f` is a pointer to a member function of a class `T` and `t1` is not one of the types described in the previous item;

— `t1.*f` when `N == 1` and `f` is a pointer to member data of a class `T` and `t1` is an object of type `T` or a reference to an object of type `T` or a reference to an object of a type derived from `T`;

— `(*t1).*f` when `N == 1` and `f` is a pointer to member data of a class `T` and `t1` is not one of the types described in the previous item;

— `f(t1, t2, ..., tN)` in all other cases.

1 Define *INVOKE*`(f, t1, t2, ..., tN, R)` as *INVOKE*`(f, t1, t2, ..., tN)` implicitly converted to `R`.

2 If a call wrapper (20.291.1) has a *weak result type* the type of its member type `result_type` is based on the type `T` of the wrapper's target object (20.291.1):

(2.1) — if `T` is a pointer to function type, `result_type` shall be a synonym for the return type of `T`;

(2.2) — if `T` is a pointer to member function, `result_type` shall be a synonym for the return type of `T`;

(2.3) — if `T` is a class type with a member type `result_type`, then `result_type` shall be a synonym for `T::result_type`;

(2.4) — otherwise `result_type` shall not be defined.

3

Every call wrapper (20.291.1) shall be `MoveConstructible`. A *simple call wrapper* is a call wrapper that is `CopyConstructible` and `CopyAssignable` and whose copy constructor, move constructor, and assignment operator do not throw exceptions. A *forwarding call wrapper* is a call wrapper that can be called with an arbitrary argument list and delivers the arguments to the wrapped callable object as references. This forwarding step shall ensure that rvalue arguments are delivered as rvalue-references and lvalue arguments are delivered as lvalue-references. [*Note:* In a typical implementation forwarding call wrappers have an overloaded function call operator of the form

```
template<class... UnBoundArgs>
R operator()(UnBoundArgs&&... unbound_args) cv-qual;
```

— *end note*]

20.339.1 Class template `reference_wrapper` [refwrap]

```
namespace std {
  template <class T> class reference_wrapper {
  public :
    // types
    typedef T type;
    typedef see below result_type;                // not always defined
    typedef see below argument_type;              // not always defined
    typedef see below first_argument_type;        // not always defined
    typedef see below second_argument_type;       // not always defined

    // construct/copy/destroy
    reference_wrapper(T&) noexcept;
    reference_wrapper(T&&) = delete;      // do not bind to temporary objects
    reference_wrapper(const reference_wrapper& x) noexcept;

    // assignment
    reference_wrapper& operator=(const reference_wrapper& x) noexcept;

    // access
    operator T& () const noexcept;
    T& get() const noexcept;

    // invocation
    template <class... ArgTypes>
    result_of_t<T&(ArgTypes&&...)>
    operator() (ArgTypes&&...) const;
  };
}
```

1 `reference_wrapper<T>` is a `CopyConstructible` and `CopyAssignable` wrapper around a reference to an object or function of type `T`.

2 `reference_wrapper<T>` has a weak result type (20.295.1). If `T` is a function type, `result_type` shall be a synonym for the return type of `T`.

3 The template specialization `reference_wrapper<T>` shall define a nested type named `argument_type` as a synonym for `T1` only if the type `T` is any of the following:

(3.1) — a function type or a pointer to function type taking one argument of type `T1`

(3.2) — a pointer to member function `R T0::f` *cv* (where *cv* represents the member function's cv-qualifiers); the type `T1` is *cv* `T0*`

(3.3) — a class type with a member type `argument_type`; the type `T1` is `T::argument_type`.

4 The template instantiation `reference_wrapper<T>` shall define two nested types named `first_argument_type` and `second_argument_type` as synonyms for `T1` and `T2`, respectively, only if the type `T` is any of the following:

(4.1) — a function type or a pointer to function type taking two arguments of types `T1` and `T2`

(4.2) — a pointer to member function `R T0::f(T2)` *cv* (where *cv* represents the member function's cv-qualifiers); the type `T1` is *cv* `T0*`

(4.3) — a class type with member types `first_argument_type` and `second_argument_type`; the type `T1` is `T::first_argument_type` and the type `T2` is `T::second_argument_type`.

20.339.1.1 `reference_wrapper` construct/copy/destroy [refwrap.const]

```
reference_wrapper(T& t) noexcept;
```

1 *Effects:* Constructs a `reference_wrapper` object that stores a reference to `t`.

```
reference_wrapper(const reference_wrapper& x) noexcept;
```

2 *Effects:* Constructs a `reference_wrapper` object that stores a reference to `x.get()`.

20.339.1.2 `reference_wrapper` assignment [refwrap.assign]

```
reference_wrapper& operator=(const reference_wrapper& x) noexcept;
```

1 *Postconditions:* `*this` stores a reference to `x.get()`.

20.339.1.3 `reference_wrapper` access [refwrap.access]

```
operator T& () const noexcept;
```

1 *Returns:* The stored reference.

```
T& get() const noexcept;
```

2 *Returns:* The stored reference.

20.339.1.4 reference_wrapper invocation [refwrap.invoke]

```
template <class... ArgTypes>
  result_of_t<T&(ArgTypes&&... )>
    operator()(ArgTypes&&... args) const;
```

1 *Returns:* *INVOKE*`(get(), std::forward<ArgTypes>(args)...)`. (20.295.1)

2 *Remark:* `operator()` is described for exposition only. Implementations are not required to provide an actual `reference_wrapper::operator()`. Implementations are permitted to support `reference_wrapper` function invocation through multiple overloaded operators or through other means.

20.339.1.5 reference_wrapper helper functions [refwrap.helpers]

```
template <class T> reference_wrapper<T> ref(T& t) noexcept;
```

1 *Returns:* `reference_wrapper<T>(t)`

```
template <class T> reference_wrapper<T> ref(reference_wrapper<T> t) noexcept;
```

2 *Returns:* `ref(t.get())`

```
template <class T> reference_wrapper<const T> cref(const T& t) noexcept;
```

3 *Returns:* `reference_wrapper <const T>(t)`

```
template <class T> reference_wrapper<const T> cref(reference_wrapper<T> t) noexcept;
```

4 *Returns:* `cref(t.get());`

20.339.2 Arithmetic operations [arithmetic.operations]

1 The library provides basic function object classes for all of the arithmetic operators in the language (5.2851, 5.2882).

```
template <class T = void> struct plus {
  constexpr T operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef T result_type;
};
```

2 `operator()` returns `x + y`.

```
template <class T = void> struct minus {
  constexpr T operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef T result_type;
};
```

3 `operator()` returns `x - y`.

```
template <class T = void> struct multiplies {
  constexpr T operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef T result_type;
};
```

4 `operator()` returns `x * y`.

```
template <class T = void> struct divides {
  constexpr T operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef T result_type;
};
```

5 `operator()` returns `x / y`.

```
template <class T = void> struct modulus {
  constexpr T operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef T result_type;
};
```

6 `operator()` returns `x % y`.

```
template <class T = void> struct negate {
  constexpr T operator()(const T& x) const;
  typedef T argument_type;
  typedef T result_type;
};
```

7 `operator()` returns `-x`.

```
template <> struct plus<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) + std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

8 `operator()` returns `std::forward<T>(t) + std::forward<U>(u)`.

```
template <> struct minus<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) - std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

9 `operator()` returns `std::forward<T>(t) - std::forward<U>(u)`.

```
template <> struct multiplies<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) * std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

10 `operator()` returns `std::forward<T>(t) * std::forward<U>(u)`.

```
template <> struct divides<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) / std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

11 `operator()` returns `std::forward<T>(t) / std::forward<U>(u)`.

```
template <> struct modulus<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) % std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

12 `operator()` returns `std::forward<T>(t) % std::forward<U>(u)`.

```
template <> struct negate<void> {
  template <class T> constexpr auto operator()(T&& t) const
    -> decltype(-std::forward<T>(t));

  typedef unspecified  is_transparent;
};
```

13 `operator()` returns `-std::forward<T>(t)`.

20.339.3 Comparisons [comparisons]

1

The library provides basic function object classes for all of the comparison operators in the language (5.3203, 5.3247).

```
template <class T = void> struct equal_to {
  constexpr bool operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef bool result_type;
};
```

1 `operator()` returns `x == y`.

```
template <class T = void> struct not_equal_to {
  constexpr bool operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef bool result_type;
};
```

2 `operator()` returns `x != y`.

```
template <class T = void> struct greater {
  constexpr bool operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef bool result_type;
};
```

3

`operator()` returns `x > y`.

```
template <class T = void> struct less {
  constexpr bool operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef bool result_type;
};
```

1 `operator()` returns `x < y`.

```
template <class T = void> struct greater_equal {
  constexpr bool operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef bool result_type;
};
```

2 `operator()` returns `x >= y`.

```
template <class T = void> struct less_equal {
  constexpr bool operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef bool result_type;
};
```

3 `operator()` returns `x <= y`.

```
template <> struct equal_to<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) == std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

4 `operator()` returns `std::forward<T>(t) == std::forward<U>(u)`.

```
template <> struct not_equal_to<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) != std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

5 `operator()` returns `std::forward<T>(t) != std::forward<U>(u)`.

```
template <> struct greater<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) > std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

6 `operator()` returns `std::forward<T>(t) > std::forward<U>(u)`.

```
template <> struct less<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) < std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

7 `operator()` returns `std::forward<T>(t) < std::forward<U>(u)`.

```
template <> struct greater_equal<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) >= std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

8 `operator()` returns `std::forward<T>(t) >= std::forward<U>(u)`.

```
template <> struct less_equal<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) <= std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

9 `operator()` returns `std::forward<T>(t) <= std::forward<U>(u)`.

10

For templates `greater`, `less`, `greater_equal`, and `less_equal`, the specializations for any pointer type yield a total order, even if the built-in operators `<`, `>`, `<=`, `>=` do not.

20.357.1 Logical operations [logical.operations]

1 The library provides basic function object classes for all of the logical operators in the language (5.3286, 5.3322, 5.1898.1).

```
template <class T = void> struct logical_and {
  constexpr bool operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef bool result_type;
};
```

2 `operator()` returns `x && y`.

```
template <class T = void> struct logical_or {
  constexpr bool operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef bool result_type;
};
```

3 `operator()` returns `x || y`.

```
template <class T = void> struct logical_not {
  constexpr bool operator()(const T& x) const;
  typedef T argument_type;
  typedef bool result_type;
};
```

4 `operator()` returns `!x`.

```
template <> struct logical_and<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) && std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

5 `operator()` returns `std::forward<T>(t) && std::forward<U>(u)`.

```
template <> struct logical_or<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) || std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

6 `operator()` returns `std::forward<T>(t) || std::forward<U>(u)`.

```
template <> struct logical_not<void> {
  template <class T> constexpr auto operator()(T&& t) const
    -> decltype(!std::forward<T>(t));

  typedef unspecified  is_transparent;
};
```

7 `operator()` returns `!std::forward<T>(t)`.

20.357.2 Bitwise operations [bitwise.operations]

1 The library provides basic function object classes for all of the bitwise operators in the language (5.3274, 5.3282, 5.3279, 5.1898.1).

```
template <class T = void> struct bit_and {
  constexpr T operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef T result_type;
};
```

2 `operator()` returns `x & y`.

```
template <class T = void> struct bit_or {
  constexpr T operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef T result_type;
};
```

3 `operator()` returns `x | y`.

```
template <class T = void> struct bit_xor {
  constexpr T operator()(const T& x, const T& y) const;
  typedef T first_argument_type;
  typedef T second_argument_type;
  typedef T result_type;
};
```

4 `operator()` returns `x ^ y`.

```
template <class T = void> struct bit_not {
  constexpr T operator()(const T& x) const;
  typedef T argument_type;
  typedef T result_type;
};
```

5 `operator()` returns `~x`.

```
template <> struct bit_and<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) & std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

6 `operator()` returns `std::forward<T>(t) & std::forward<U>(u)`.

```
template <> struct bit_or<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) | std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

7 `operator()` returns `std::forward<T>(t) | std::forward<U>(u)`.

```
template <> struct bit_xor<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) ^ std::forward<U>(u));

  typedef unspecified  is_transparent;
};
```

8 `operator()` returns `std::forward<T>(t) ^ std::forward<U>(u)`.

```
template <> struct bit_not<void> {
  template <class T> constexpr auto operator()(T&& t) const
    -> decltype(~std::forward<T>(t));

  typedef unspecified  is_transparent;
};
```

9 `operator()` returns `~std::forward<T>(t)`.

20.357.3 Negators [negators]

1 Negators `not1` and `not2` take a unary and a binary predicate, respectively, and return their complements (5.1898.1).

```
template <class Predicate>
  class unary_negate {
public:
  constexpr explicit unary_negate(const Predicate& pred);
  constexpr bool operator()(const typename Predicate::argument_type& x) const;
  typedef typename Predicate::argument_type argument_type;
  typedef bool result_type;
};
```

2 `operator()` returns `!pred(x)`.

```
template <class Predicate>
  constexpr unary_negate<Predicate> not1(const Predicate& pred);
```

3 *Returns:* `unary_negate<Predicate>(pred)`.

```
template <class Predicate>
  class binary_negate {
  public:
    constexpr explicit binary_negate(const Predicate& pred);
    constexpr bool operator()(const typename Predicate::first_argument_type& x,
        const typename Predicate::second_argument_type& y) const;
  typedef typename Predicate::first_argument_type first_argument_type;
  typedef typename Predicate::second_argument_type second_argument_type;
  typedef bool result_type;
  };
```

4 `operator()` returns `!pred(x,y)`.

```
template <class Predicate>
  constexpr binary_negate<Predicate> not2(const Predicate& pred);
```

5 *Returns:* `binary_negate<Predicate>(pred)`.

20.357.4 Function object binders [func.bind]

1 This subclause describes a uniform mechanism for binding arguments of callable objects.

20.357.4.1 Class template `is_bind_expression` [func.bind.isbind]

```
namespace std {
  template<class T> struct is_bind_expression; // see below
}
```

1 `is_bind_expression` can be used to detect function objects generated by `bind`. `bind` uses `is_bind_expression` to detect subexpressions.

2 Instantiations of the `is_bind_expression` template shall meet the UnaryTypeTrait requirements (20.450.1). The implementation shall provide a definition that has a BaseCharacteristic of `true_type` if `T` is a type returned from `bind`, otherwise it shall have a BaseCharacteristic of `false_type`. A program may specialize this template for a user-defined type `T` to have a BaseCharacteristic of `true_type` to indicate that `T` should be treated as a subexpression in a `bind` call.

20.357.4.2 Class template `is_placeholder` [func.bind.isplace]

```
namespace std {
  template<class T> struct is_placeholder; // see below
}
```

1 `is_placeholder` can be used to detect the standard placeholders `_1`, `_2`, and so on. `bind` uses `is_placeholder` to detect placeholders.

2

Instantiations of the `is_placeholder` template shall meet the UnaryTypeTrait requirements (20.450.1). The implementation shall provide a definition that has the BaseCharacteristic of `integral_constant<int, J>` if `T` is the type of `std::placeholders::_J`, otherwise it shall have a BaseCharacteristic of `integral_constant<int, 0>`. A program may specialize this template for a user-defined type `T` to have a BaseCharacteristic of `integral_constant<int, N>` with `N > 0` to indicate that `T` should be treated as a placeholder type.

20.358.0.1 Function template `bind` [func.bind.bind]

1

In the text that follows, the following names have the following meanings:

— `FD` is the type `decay_t<F>`,

— `fd` is an lvalue of type `FD` constructed from `std::forward<F>(f)`,

— `Ti` is the ith type in the template parameter pack `BoundArgs`,

— `TiD` is the type `decay_t<Ti>`,

— `ti` is the ith argument in the function parameter pack `bound_args`,

— `tid` is an lvalue of type `TiD` constructed from `std::forward<Ti>(ti)`,

— `Uj` is the jth deduced type of the `UnBoundArgs&&...` parameter of the forwarding call wrapper, and

— `uj` is the jth argument associated with `Uj`.

```
template<class F, class... BoundArgs>
  unspecified  bind(F&& f, BoundArgs&&... bound_args);
```

1

Requires: `is_constructible<FD, F>::value` shall be `true`. For each `Ti` in `BoundArgs`, `is_constructible<TiD, Ti>::value` shall be `true`. *INVOKE* `(fd, w1, w2, ..., wN)` (20.295.1) shall be a valid expression for some values *w1, w2, ..., wN*, where `N == sizeof...(bound_args)`.

1 *Returns:* A forwarding call wrapper `g` with a weak result type (20.295.1). The effect of `g(u1, u2, ..., uM)` shall be *`INVOKE`*`(fd, std::forward<V1>(v1), std::forward<V2>(v2), ..., std::forward<VN>(vN), result_of_t<FD cv & (V1, V2, ..., VN)>)`, where *`cv`* represents the *cv*-qualifiers of `g` and the values and types of the bound arguments `v1, v2, ..., vN` are determined as specified below. The copy constructor and move constructor of the forwarding call wrapper shall throw an exception if and only if the corresponding constructor of `FD` or of any of the types `TiD` throws an exception.

1 *Throws:* Nothing unless the construction of `fd` or of one of the values `tid` throws an exception.

2 *Remarks:* The return type shall satisfy the requirements of `MoveConstructible`. If all of `FD` and `TiD` satisfy the requirements of `CopyConstructible`, then the return type shall satisfy the requirements of `CopyConstructible`. [*Note:* This implies that all of `FD` and `TiD` are `MoveConstructible`. — *end note*]

```
template<class R, class F, class... BoundArgs>
  unspecified  bind(F&& f, BoundArgs&&... bound_args);
```

1 *Requires:* `is_constructible<FD, F>::value` shall be `true`. For each `Ti` in `BoundArgs`, `is_constructible<TiD, Ti>::value` shall be `true`. *`INVOKE`*`(fd, w1, w2, ..., wN)` shall be a valid expression for some values *w1, w2, ..., wN*, where `N == sizeof...(bound_args)`.

2 *Returns:* A forwarding call wrapper `g` with a nested type `result_type` defined as a synonym for `R`. The effect of `g(u1, u2, ..., uM)` shall be *`INVOKE`*`(fd, std::forward<V1>(v1), std::forward<V2>(v2), ..., std::forward<VN>(vN), R)`, where the values and types of the bound arguments `v1, v2, ..., vN` are determined as specified below. The copy constructor and move constructor of the forwarding call wrapper shall throw an exception if and only if the corresponding constructor of `FD` or of any of the types `TiD` throws an exception.

1 *Throws:* Nothing unless the construction of `fd` or of one of the values `tid` throws an exception.

2 *Remarks:* The return type shall satisfy the requirements of `MoveConstructible`. If all of `FD` and `TiD` satisfy the requirements of `CopyConstructible`, then the return type shall satisfy the requirements of `CopyConstructible`. [*Note:* This implies that all of `FD` and `TiD` are `MoveConstructible`. — *end note*]

3 The values of the *bound arguments* `v1, v2, ..., vN` and their corresponding types `V1, V2, ..., VN` depend on the types `TiD` derived from the call to `bind` and the *cv*-qualifiers *cv* of the call wrapper `g` as follows:

— if `TiD` is `reference_wrapper<T>`, the argument is `tid.get()` and its type `Vi` is `T&`;

— if the value of `is_bind_expression<TiD>::value` is `true`, the argument is `tid(std::forward<Uj>(uj)...)` and its type `Vi` is `result_of_t<TiD cv & (Uj&&...)>&&`;

— if the value `j` of `is_placeholder<TiD>::value` is not zero, the argument is `std::forward<Uj>(uj)` and its type `Vi` is `Uj&&`;

— otherwise, the value is `tid` and its type `Vi` is `TiD cv &`.

20.379.0.1 Placeholders [func.bind.place]

```
namespace std {
  namespace placeholders {
    // M is the implementation-defined number of placeholders
```

```
    extern unspecified  _1;
    extern unspecified  _2;
                .
                .
                .
    extern unspecified _M;
  }
}
```

1 All placeholder types shall be `DefaultConstructible` and `CopyConstructible`, and their default constructors and copy/move constructors shall not throw exceptions. It is implementation-defined whether placeholder types are `CopyAssignable`. `CopyAssignable` placeholders' copy assignment operators shall not throw exceptions.

20.379.1 Function template `mem_fn` [func.memfn]

```
template<class R, class T> unspecified  mem_fn(R T::* pm);
```

1

Returns: A simple call wrapper (20.291.1) `fn` such that the expression `fn(t, a2, ..., aN)` is equivalent to *`INVOKE`*`(pm, t, a2, ..., aN)` (20.295.1). `fn` shall have a nested type `result_type` that is a synonym for the return type of `pm` when `pm` is a pointer to member function.

1

The simple call wrapper shall define two nested types named `argument_type` and `result_type` as synonyms for *`cv`* `T*` and `Ret`, respectively, when `pm` is a pointer to member function with cv-qualifier *cv* and taking no arguments, where *Ret* is `pm`'s return type.

1

The simple call wrapper shall define three nested types named `first_argument_type`, `second_argument_type`, and `result_type` as synonyms for *`cv`* `T*`, `T1`, and `Ret`, respectively, when `pm` is a pointer to member function with cv-qualifier *cv* and taking one argument of type `T1`, where *Ret* is `pm`'s return type.

1 *Throws:* Nothing.

20.385.1 Polymorphic function wrappers [func.wrap]

1 This subclause describes a polymorphic wrapper class that encapsulates arbitrary callable objects.

20.385.1.1 Class `bad_function_call` [func.wrap.badcall]

1

An exception of type `bad_function_call` is thrown by `function::operator()` (20.435.0.0.1) when the function wrapper object has no target.

```
namespace std {
  class bad_function_call : public std::exception {
  public:
    // 20.387.0.0.1, constructor:
    bad_function_call() noexcept;
  };
} // namespace std
```

20.387.0.0.1 `bad_function_call` constructor [func.wrap.badcall.const]

```
bad_function_call() noexcept;
```

1 *Effects:* constructs a `bad_function_call` object.

20.387.0.1 Class template function [func.wrap.func]

```
namespace std {
  template<class> class function; // undefined

  template<class R, class... ArgTypes>
  class function<R(ArgTypes...)> {
  public:
    typedef R result_type;
    typedef T1 argument_type;           // only if sizeof...(ArgTypes) == 1 and
                                        // the type in ArgTypes is T1
    typedef T1 first_argument_type;     // only if sizeof...(ArgTypes) == 2 and
                                        // ArgTypes contains T1 and T2
    typedef T2 second_argument_type;    // only if sizeof...(ArgTypes) == 2 and
                                        // ArgTypes contains T1 and T2

    // 20.401.0.0.1, construct/copy/destroy:
    function() noexcept;
    function(nullptr_t) noexcept;
    function(const function&);
    function(function&&);
    template<class F> function(F);
    template<class A> function(allocator_arg_t, const A&) noexcept;
    template<class A> function(allocator_arg_t, const A&,
      nullptr_t) noexcept;
    template<class A> function(allocator_arg_t, const A&,
      const function&);
    template<class A> function(allocator_arg_t, const A&,
      function&&);
    template<class F, class A> function(allocator_arg_t, const A&, F);

    function& operator=(const function&);
    function& operator=(function&&);
    function& operator=(nullptr_t);
    template<class F> function& operator=(F&&);
    template<class F> function& operator=(reference_wrapper<F>) noexcept;

    ~function();

    // 20.434.0.0.1, function modifiers:
    void swap(function&) noexcept;
    template<class F, class A> void assign(F&&, const A&);

    // 20.434.0.0.2, function capacity:
    explicit operator bool() const noexcept;

    // 20.435.0.0.1, function invocation:
    R operator()(ArgTypes...) const;

    // 20.442.0.0.1, function target access:
    const std::type_info& target_type() const noexcept;
    template<class T>       T* target() noexcept;
    template<class T> const T* target() const noexcept;

  };
```

```
  // 20.443.0.0.1, Null pointer comparisons:
  template <class R, class... ArgTypes>
    bool operator==(const function<R(ArgTypes...)>&, nullptr_t) noexcept;

  template <class R, class... ArgTypes>
    bool operator==(nullptr_t, const function<R(ArgTypes...)>&) noexcept;

  template <class R, class... ArgTypes>
    bool operator!=(const function<R(ArgTypes...)>&, nullptr_t) noexcept;

  template <class R, class... ArgTypes>
    bool operator!=(nullptr_t, const function<R(ArgTypes...)>&) noexcept;

  // 20.443.0.0.2, specialized algorithms:
  template <class R, class... ArgTypes>
    void swap(function<R(ArgTypes...)>&, function<R(ArgTypes...)>&);

  template<class R, class... ArgTypes, class Alloc>
    struct uses_allocator<function<R(ArgTypes...)>, Alloc>
      : true_type { };
}
```

1

The `function` class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (20.291.1), given a call signature (20.291.1), allowing functions to be first-class objects.

1

A callable object `f` of type `F` is *Callable* for argument types `ArgTypes` and return type `R` if the expression *`INVOKE`*`(f, declval<ArgTypes>()..., R)`, considered as an unevaluated operand (Clause 5), is well formed (20.295.1).

1

The `function` class template is a call wrapper (20.291.1) whose call signature (20.291.1) is `R(ArgTypes...)`.

20.401.0.0.1 `function` construct/copy/destroy [func.wrap.func.con]

1 When any `function` constructor that takes a first argument of type `allocator_arg_t` is invoked, the second argument shall have a type that conforms to the requirements for Allocator (Table 17.165.0.1). A copy of the allocator argument is used to allocate memory, if necessary, for the internal data structures of the constructed `function` object.

```
function() noexcept;
template <class A> function(allocator_arg_t, const A& a) noexcept;
```

2 *Postconditions:* `!*this`.

```
function(nullptr_t) noexcept;
template <class A> function(allocator_arg_t, const A& a, nullptr_t) noexcept;
```

3 *Postconditions:* `!*this`.

```
function(const function& f);
template <class A> function(allocator_arg_t, const A& a, const function& f);
```

4 *Postconditions:* `!*this` if `!f`; otherwise, `*this` targets a copy of `f.target()`.

5

Throws: shall not throw exceptions if `f`'s target is a callable object passed via `reference_wrapper` or a function pointer. Otherwise, may throw `bad_alloc` or any exception thrown by the copy constructor of the stored callable object. [*Note:* Implementations are encouraged to avoid the use of dynamically allocated memory for small callable objects, for example, where `f`'s target is an object holding only a pointer or reference to an object and a member function pointer. — *end note*]

```
function(function&& f);
template <class A> function(allocator_arg_t, const A& a, function&& f);
```

1

Effects: If `!f`, `*this` has no target; otherwise, move-constructs the target of `f` into the target of `*this`, leaving `f` in a valid state with an unspecified value.

```
template<class F> function(F f);
template <class F, class A> function(allocator_arg_t, const A& a, F f);
```

1 *Requires:* `F` shall be `CopyConstructible`.

2

Remarks: These constructors shall not participate in overload resolution unless `f` is Callable (20.387.0.1) for argument types `ArgTypes...` and return type `R`.

1

Postconditions: `!*this` if any of the following hold:

— `f` is a null function pointer value.

— `f` is a null member pointer value.

— `F` is an instance of the `function` class template, and `!f`.

1

Otherwise, `*this` targets a copy of `f` initialized with `std::move(f)`. [*Note:* Implementations are encouraged to avoid the use of dynamically allocated memory for small callable objects, for example, where `f`'s target is an object holding only a pointer or reference to an object and a member function pointer. — *end note*]

1

Throws: shall not throw exceptions when `f` is a function pointer or a `reference_wrapper<T>` for some `T`. Otherwise, may throw `bad_alloc` or any exception thrown by `F`'s copy or move constructor.

```
function& operator=(const function& f);
```

1 *Effects:* `function(f).swap(*this);`

2 *Returns:* `*this`

```
function& operator=(function&& f);
```

3 *Effects:* Replaces the target of `*this` with the target of `f`.

4 *Returns:* `*this`

```
function& operator=(nullptr_t);
```

5 *Effects:* If `*this != nullptr`, destroys the target of `this`.

6 *Postconditions:* `!(*this)`.

7 *Returns:* `*this`

```
template<class F> function& operator=(F&& f);
```

8 *Effects:* `function(std::forward<F>(f)).swap(*this);`

9 *Returns:* `*this`

10 *Remarks:* This assignment operator shall not participate in overload resolution unless `declval<typename decay<F>::type&>()` is Callable (20.387.0.1) for argument types `ArgTypes...` and return type `R`.

```
template<class F> function& operator=(reference_wrapper<F> f) noexcept;
```

11 *Effects:* `function(f).swap(*this);`

12 *Returns:* `*this`

```
~function();
```

13 *Effects:* If `*this != nullptr`, destroys the target of `this`.

20.434.0.0.1 `function` modifiers [func.wrap.func.mod]

```
void swap(function& other) noexcept;
```

1 *Effects:* interchanges the targets of `*this` and `other`.

```
template<class F, class A>
  void assign(F&& f, const A& a);
```

2 *Effects:* `function(allocator_arg, a, std::forward<F>(f)).swap(*this)`

20.434.0.0.2 `function` capacity [func.wrap.func.cap]

```
explicit operator bool() const noexcept;
```

1

Returns: `true` if `*this` has a target, otherwise `false`.

20.435.0.0.1 `function` invocation [func.wrap.func.inv]

```
R operator()(ArgTypes... args) const
```

1

Effects: *`INVOKE`*`(f, std::forward<ArgTypes>(args)..., R)` (20.295.1), where `f` is the target object (20.291.1) of `*this`.

1 *Returns:* Nothing if `R` is `void`, otherwise the return value of *`INVOKE`*`(f, std::forward<ArgTypes>(args)..., R)`.

1 *Throws:* `bad_function_call` if `!*this`; otherwise, any exception thrown by the wrapped callable object.

20.442.0.0.1 function target access [func.wrap.func.targ]

```
const std::type_info& target_type() const noexcept;
```

1 *Returns:* If `*this` has a target of type `T`, `typeid(T)`; otherwise, `typeid(void)`.

```
template<class T>       T* target() noexcept;
template<class T> const T* target() const noexcept;
```

2 *Requires:* `T` shall be a type that is Callable (20.387.0.1) for parameter types `ArgTypes` and return type `R`.

3 *Returns:* If `target_type() == typeid(T)` a pointer to the stored function target; otherwise a null pointer.

20.443.0.0.1 null pointer comparison operators [func.wrap.func.nullptr]

```
template <class R, class... ArgTypes>
  bool operator==(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;
template <class R, class... ArgTypes>
  bool operator==(nullptr_t, const function<R(ArgTypes...)>& f) noexcept;
```

1 *Returns:* `!f`.

```
template <class R, class... ArgTypes>
  bool operator!=(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;
template <class R, class... ArgTypes>
  bool operator!=(nullptr_t, const function<R(ArgTypes...)>& f) noexcept;
```

2 *Returns:* `(bool) f`.

20.443.0.0.2 specialized algorithms [func.wrap.func.alg]

```
template<class R, class... ArgTypes>
  void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2);
```

1 *Effects:* `f1.swap(f2);`

20.443.1 Class template `hash` [unord.hash]

1

The unordered associative containers defined in 23.932 use specializations of the class template `hash` as the default hash function. For all object types `Key` for which there exists a specialization `hash<Key>`, and for all enumeration types (7.1001) `Key`, the instantiation `hash<Key>` shall:

— satisfy the `Hash` requirements (17.159.0.1), with `Key` as the function call argument type, the `DefaultConstructible` requirements (Table 19), the `CopyAssignable` requirements (Table 23),

— be swappable (17.143.0.1) for lvalues,

— provide two nested types `result_type` and `argument_type` which shall be synonyms for `size_t` and `Key`, respectively,

— satisfy the requirement that if `k1 == k2` is true, `h(k1) == h(k2)` is also true, where `h` is an object of type `hash<Key>` and `k1` and `k2` are objects of type `Key`;

— satisfy the requirement that the expression `h(k)`, where `h` is an object of type `hash<Key>` and `k` is an object of type `Key`, shall not throw an exception unless `hash<Key>` is a user-defined specialization that depends on at least one user-defined type.

```
template <> struct hash<bool>;
template <> struct hash<char>;
template <> struct hash<signed char>;
template <> struct hash<unsigned char>;
template <> struct hash<char16_t>;
template <> struct hash<char32_t>;
template <> struct hash<wchar_t>;
template <> struct hash<short>;
template <> struct hash<unsigned short>;
template <> struct hash<int>;
template <> struct hash<unsigned int>;
template <> struct hash<long>;
template <> struct hash<unsigned long>;
```

```
template <> struct hash<long long>;
template <> struct hash<unsigned long long>;
template <> struct hash<float>;
template <> struct hash<double>;
template <> struct hash<long double>;
template <class T> struct hash<T*>;
```

1 The template specializations shall meet the requirements of class template `hash` (20.443.1).

20.449 Metaprogramming and type traits [meta]

1

This subclause describes components used by C++ programs, particularly in templates, to support the widest possible range of types, optimise template code usage, detect type related user errors, and perform type inference and transformation at compile time. It includes type classification traits, type property inspection traits, and type transformations. The type classification traits describe a complete taxonomy of all possible C++ types, and state where in that taxonomy a given type belongs. The type property inspection traits allow important characteristics of types or of combinations of types to be inspected. The type transformations allow certain properties of types to be manipulated.

20.450.1 Requirements [meta.rqmts]

1

A *UnaryTypeTrait* describes a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the property being described. It shall be `DefaultConstructible`, `CopyConstructible`, and publicly and unambiguously derived, directly or indirectly, from its *BaseCharacteristic*, which is a specialization of the template `integral_constant` (20.457.1), with the arguments to the template `integral_constant` determined by the requirements for the particular property being described. The member names of the BaseCharacteristic shall not be hidden and shall be unambiguously available in the UnaryTypeTrait.

1 A *BinaryTypeTrait* describes a relationship between two types. It shall be a class template that takes two template type arguments and, optionally, additional arguments that help define the relationship being described. It shall be `DefaultConstructible`, `CopyConstructible`, and publicly and unambiguously derived, directly or indirectly, from its *BaseCharacteristic*, which is a specialization of the template `integral_constant` (20.457.1), with the arguments to the template `integral_constant` determined by the requirements for the particular relationship being described. The member names of the BaseCharacteristic shall not be hidden and shall be unambiguously available in the BinaryTypeTrait.

2 A *TransformationTrait* modifies a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the modification. It shall define a publicly accessible nested type named `type`, which shall be a synonym for the modified type.

20.452.1 Header `<type_traits>` synopsis [meta.type.synop]

```
namespace std {
  // 20.457.1, helper class:
  template <class T, T v> struct integral_constant;

template <class T>
  using decay_t           = typename decay<T>::type;
template <bool b, class T = void>
  using enable_if_t       = typename enable_if<b,T>::type;
template <bool b, class T, class F>
  using conditional_t     = typename conditional<b,T,F>::type;
template <class... T>
  using common_type_t     = typename common_type<T...>::type;
```

```
  template <class T>
    using underlying_type_t = typename underlying_type<T>::type;
  template <class T>
    using result_of_t       = typename result_of<T>::type;
} // namespace std
```

1

The behavior of a program that adds specializations for any of the class templates defined in this subclause is undefined unless otherwise specified.

20.457.1 Helper classes [meta.help]

```
namespace std {
  template <class T, T v>
  struct integral_constant {
    static constexpr T value = v;
    typedef T value_type;
    typedef integral_constant<T,v> type;
    constexpr operator value_type() const noexcept { return value; }
    constexpr value_type operator()() const noexcept { return value; }
  };
  typedef integral_constant<bool, true> true_type;
  typedef integral_constant<bool, false> false_type;
}
```

1 The class template `integral_constant` and its associated typedefs `true_type` and `false_type` are used as base classes to define the interface for various type traits.

20.457.2 Unary type traits [meta.unary]

1 This sub-clause contains templates that may be used to query the properties of a type at compile time.

2

Each of these templates shall be a UnaryTypeTrait (20.450.1) with a BaseCharacteristic of `true_type` if the corresponding condition is true, otherwise `false_type`.

20.458.0.1 Primary type categories [meta.unary.cat]

1

The primary type categories correspond to the descriptions given in section 3.2955 of the C++ standard.

1 For any given type `T`, the result of applying one of these templates to `T` and to *cv-qualified* `T` shall yield the same result.

2

[*Note:* For any given type `T`, exactly one of the primary type categories has a `value` member that evaluates to `true`. — *end note*]

Table 47 — Primary type category predicates

Template	Condition	Comments
`template <class T>` `struct is_void;`	`T` is `void`	
`template <class T>` `struct is_null_pointer;`	`T` is `std::nullptr_t` (3.3151.1)	

Table 47 — Primary type category predicates (continued)

Template	Condition	Comments
`template <class T>` `struct is_integral;`	`T` is an integral type (3.3151.1)	
`template <class T>` `struct is_floating_point;`	`T` is a floating point type (3.3151.1)	
`template <class T>` `struct is_array;`	`T` is an array type (3.3568.1) of known or unknown extent	Class template `array` (23.542.1) is not an array type.
`template <class T>` `struct is_pointer;`	`T` is a pointer type (3.3568.1)	Includes pointers to functions but not pointers to non-static members.
`template <class T>` `struct is_lvalue_reference;`	`T` is an lvalue reference type (8.97.1)	
`template <class T>` `struct is_rvalue_reference;`	`T` is an rvalue reference type (8.97.1)	
`template <class T>` `struct is_member_object_pointer;`	`T` is a pointer to non-static data member	

`template <class T>`
`struct`
`is_member_function_pointer;`
	`T` is a pointer to non-static member function	

`template <class T>` `struct is_enum;`	`T` is an enumeration type (3.3568.1)	
`template <class T>` `struct is_union;`	`T` is a union type (3.3568.1)	
`template <class T>` `struct is_class;`	`T` is a class type but not a union type (3.3568.1)	
`template <class T>` `struct is_function;`	`T` is a function type (3.3568.1)	

20.467.0.1 Composite type traits [meta.unary.comp]

1 These templates provide convenient compositions of the primary type categories, corresponding to the descriptions given in section 3.2955.

2 For any given type `T`, the result of applying one of these templates to `T`, and to *cv-qualified* `T` shall yield the same result.

Table 48 — Composite type category predicates

Template	Condition	Comments
`template <class T>` `struct is_reference;`	`T` is an lvalue reference or an rvalue reference	
`template <class T>` `struct is_arithmetic;`	`T` is an arithmetic type (3.3151.1)	
`template <class T>` `struct is_fundamental;`	`T` is a fundamental type (3.3151.1)	
`template <class T>` `struct is_object;`	`T` is an object type (3.2955)	
`template <class T>` `struct is_scalar;`	`T` is a scalar type (3.2955)	

Table 48 — Composite type category predicates (continued)

Template	Condition	Comments
`template <class T>` `struct is_compound;`	`T` is a compound type (3.3568.1)	
`template <class T>` `struct is_member_pointer;`	`T` is a pointer to non-static data member or non-static member function	

20.467.0.2 Type properties [meta.unary.prop]

1 These templates provide access to some of the more important properties of types.

2 It is unspecified whether the library defines any full or partial specializations of any of these templates.

3

For all of the class templates `X` declared in this Clause, instantiating that template with a template-argument that is a class template specialization may result in the implicit instantiation of the template argument if and only if the semantics of `X` require that the argument must be a complete type.

Table 49 — Type property predicates

Template	Condition	Preconditions
`template <class T>` `struct is_const;`	`T` is const-qualified (3.3640.1)	
`template <class T>` `struct is_volatile;`	`T` is volatile-qualified (3.3640.1)	
`template <class T>` `struct is_trivial;`	`T` is a trivial type (3.2955)	`remove_all_extents_t<T>` shall be a complete type or (possibly cv-qualified) void.
`template <class T>` `struct is_trivially_copyable;`	`T` is a trivially copyable type (3.2955)	`remove_all_extents_t<T>` shall be a complete type or (possibly cv-qualified) `void`.
`template <class T>` `struct is_standard_layout;`	`T` is a standard-layout type (3.2955)	`remove_all_extents_t<T>` shall be a complete type or (possibly cv-qualified) void.
`template <class T>` `struct is_pod;`	`T` is a POD type (3.2955)	`remove_all_extents_t<T>` shall be a complete type or (possibly cv-qualified) void.
`template <class T>` `struct is_literal_type;`	`T` is a literal type (3.2955)	`remove_all_extents_t<T>` shall be a complete type or (possibly cv-qualified) `void`.

Table 49 — Type property predicates (continued)

Template	Condition	Preconditions
`template <class T>` `struct is_empty;`	`T` is a class type, but not a union type, with no non-static data members other than bit-fields of length 0, no virtual member functions, no virtual base classes, and no base class `B` for which `is_empty<B>::value` is false.	If `T` is a non-union class type, `T` shall be a complete type.
`template <class T>` `struct is_polymorphic;`	`T` is a polymorphic class (10.113)	If `T` is a non-union class type, `T` shall be a complete type.
`template <class T>` `struct is_abstract;`	`T` is an abstract class (10.276)	If `T` is a non-union class type, `T` shall be a complete type.
`template <class T>` `struct is_final;`	`T` is a class type marked with the *class-virt-specifier* `final` (Clause 9). [*Note:* A union is a class type that can be marked with `final`. — *end note*]	If `T` is a class type, `T` shall be a complete type.
`template <class T>` `struct is_signed;`	If `is_arithmetic<T>::value` is `true`, the same result as `integral_constant<bool, T(-1) < T(0)>::value`; otherwise, `false`	
`template <class T>` `struct is_unsigned;`	If `is_arithmetic<T>::value` is `true`, the same result as `integral_constant<bool, T(0) < T(-1)>::value`; otherwise, `false`	
`template <class T, class... Args>` `struct is_constructible;`	*see below*	`T` and all types in the parameter pack `Args` shall be complete types, (possibly cv-qualified) `void`, or arrays of unknown bound.
`template <class T>` `struct is_default_constructible;`	`is_constructible<T>::value` is `true`.	`T` shall be a complete type, (possibly *cv*-qualified) `void`, or an array of unknown bound.

Table 49 — Type property predicates (continued)

Template	Condition	Preconditions
`template <class T>` `struct is_copy_constructible;`	For a referenceable type `T`, the same result as `is_constructible<T, const T&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly *cv*-qualified) `void`, or an array of unknown bound.
`template <class T>` `struct is_move_constructible;`	For a referenceable type `T`, the same result as `is_constructible<T, T&&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly *cv*-qualified) `void`, or an array of unknown bound.
`template <class T, class U>` `struct is_assignable;`	The expression `declval<T>() = declval<U>()` is well-formed when treated as an unevaluated operand (Clause 5). Access checking is performed as if in a context unrelated to `T` and `U`. Only the validity of the immediate context of the assignment expression is considered. [*Note:* The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]	`T` and `U` shall be complete types, (possibly cv-qualified) `void`, or arrays of unknown bound.
`template <class T>` `struct is_copy_assignable;`	For a referenceable type `T`, the same result as `is_assignable<T&, const T&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly *cv*-qualified) `void`, or an array of unknown bound.
`template <class T>` `struct is_move_assignable;`	For a referenceable type `T`, the same result as `is_assignable<T&, T&&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly *cv*-qualified) `void`, or an array of unknown bound.

Table 49 — Type property predicates (continued)

Template	Condition	Preconditions
`template <class T>` `struct is_destructible;`	For reference types, `is_destructible<T>::value` is `true`. For incomplete types and function types, `is_destructible<T>::value` is `false`. For object types and given `U` equal to `remove_all_extents_t<T>`, if the expression `std::declval<U&>().~U()` is well-formed when treated as an unevaluated operand (Clause 5), then `is_destructible<T>::value` is `true`, otherwise it is `false`.	`T` shall be a complete type, (possibly *cv*-qualified) `void`, or an array of unknown bound.

`template <class T, class... Args>`
`struct`
`is_trivially_constructible;`
	`is_constructible<T, Args...>::value` is `true` and the variable definition for `is_constructible`, as defined below, is known to call no operation that is not trivial (3.2955, 12).	`T` and all types in the parameter pack `Args` shall be complete types, (possibly cv-qualified) `void`, or arrays of unknown bound.

`template <class T>`
`struct`
`is_trivially_default_constructible;`
	`is_trivially_constructible<T>::value` is `true`.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.

`template <class T>`
`struct`
`is_trivially_copy_constructible;`
	For a referenceable type `T`, the same result as `is_trivially_constructible<T, const T&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.

`template <class T>`
`struct`
`is_trivially_move_constructible;`
	For a referenceable type `T`, the same result as `is_trivially_constructible<T, T&&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.

Table 49 — Type property predicates (continued)

Template	Condition	Preconditions
`template <class T, class U> struct is_trivially_assignable;`	`is_assignable<T, U>::value` is `true` and the assignment, as defined by `is_assignable`, is known to call no operation that is not trivial (3.2955, 12).	`T` and `U` shall be complete types, (possibly cv-qualified) `void`, or arrays of unknown bound.
`template <class T> struct is_trivially_copy_assignable;`	For a referenceable type `T`, the same result as `is_trivially_assignable<T&, const T&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.
`template <class T> struct is_trivially_move_assignable;`	For a referenceable type `T`, the same result as `is_trivially_assignable<T&, T&&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.
`template <class T> struct is_trivially_destructible;`	`is_destructible<T>::value` is `true` and the indicated destructor is known to be trivial.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.
`template <class T, class... Args> struct is_nothrow_constructible;`	`is_constructible<T, Args...>::value` is `true` and the variable definition for `is_constructible`, as defined below, is known not to throw any exceptions (5.2750.1).	`T` and all types in the parameter pack `Args` shall be complete types, (possibly cv-qualified) `void`, or arrays of unknown bound.
`template <class T> struct is_nothrow_default_constructible;`	`is_nothrow_constructible<T>::value` is `true`.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.
`template <class T> struct is_nothrow_copy_constructible;`	For a referenceable type `T`, the same result as `is_nothrow_constructible<T, const T&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.
`template <class T> struct is_nothrow_move_constructible;`	For a referenceable type `T`, the same result as `is_nothrow_constructible<T, T&&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.

Table 49 — Type property predicates (continued)

Template	Condition	Preconditions
`template <class T, class U>` `struct is_nothrow_assignable;`	`is_assignable<T, U>::value` is `true` and the assignment is known not to throw any exceptions (5.2750.1).	`T` and `U` shall be complete types, (possibly cv-qualified) `void`, or arrays of unknown bound.
`template <class T>` `struct is_nothrow_copy_assignable;`	For a referenceable type `T`, the same result as `is_nothrow_assignable<T&, const T&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.
`template <class T>` `struct is_nothrow_move_assignable;`	For a referenceable type `T`, the same result as `is_nothrow_assignable<T&, T&&>::value`, otherwise `false`.	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.
`template <class T>` `struct is_nothrow_destructible;`	`is_destructible<T>::value` is `true` and the indicated destructor is known not to throw any exceptions (5.2750.1).	`T` shall be a complete type, (possibly cv-qualified) void, or an array of unknown bound.
`template <class T>` `struct has_virtual_destructor;`	`T` has a virtual destructor (12.807)	If `T` is a non-union class type, `T` shall be a complete type.

1 [*Example:*

```
is_const<const volatile int>::value      // true
is_const<const int*>::value              // false
is_const<const int&>::value              // false
is_const<int[3]>::value                  // false
is_const<const int[3]>::value            // true
```

— *end example*]

2 [*Example:*

```
remove_const_t<const volatile int>  // volatile int
remove_const_t<const int* const>    // const int*
remove_const_t<const int&>          // const int&
remove_const_t<const int[3]>        // int[3]
```

— *end example*]

3 [*Example:*

```
// Given:
struct P final { };
union U1 { };
union U2 final { };
```

```
// the following assertions hold:
static_assert(!is_final<int>::value, "Error!");
static_assert( is_final<P>::value, "Error!");
static_assert(!is_final<U1>::value, "Error!");
static_assert( is_final<U2>::value, "Error!");
```

— *end example*]

4

Given the following function prototype:

```
template <class T>
  add_rvalue_reference_t<T> create() noexcept;
```

the predicate condition for a template specialization `is_constructible<T, Args...>` shall be satisfied if and only if the following variable definition would be well-formed for some invented variable `t`:

```
T t(create<Args>()...);
```

[*Note:* These tokens are never interpreted as a function declaration. — *end note*] Access checking is performed as if in a context unrelated to `T` and any of the `Args`. Only the validity of the immediate context of the variable initialization is considered. [*Note:* The evaluation of the initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]

20.560.1 Type property queries [meta.unary.prop.query]

1

This sub-clause contains templates that may be used to query properties of types at compile time.

Table 50 — Type property queries

Template	Value
`template <class T>` `struct alignment_of;`	`alignof(T)`. *Requires:* `alignof(T)` shall be a valid expression (5.2747.1)
`template <class T>` `struct rank;`	If `T` names an array type, an integer value representing the number of dimensions of `T`; otherwise, 0.

`template <class T,`
`unsigned I = 0>`
`struct extent;`
	If `T` is not an array type, or if it has rank less than or equal to `I`, or if `I` is 0 and `T` has type "array of unknown bound of `U`", then 0; otherwise, the bound (8.251.1) of the `I`'th dimension of `T`, where indexing of `I` is zero-based

1 Each of these templates shall be a `UnaryTypeTrait` (20.450.1) with a `BaseCharacteristic` of `integral_constant<size_t, Value>`.

2 [*Example:*

```
// the following assertions hold:
assert(rank<int>::value == 0);
assert(rank<int[2]>::value == 1);
assert(rank<int[][4]>::value == 2);
```

— *end example*]

3 [*Example:*

```
// the following assertions hold:
assert(extent<int>::value == 0);
assert(extent<int[2]>::value == 2);
assert(extent<int[2][4]>::value == 2);
assert(extent<int[][4]>::value == 0);
assert((extent<int, 1>::value) == 0);
assert((extent<int[2], 1>::value) == 0);
assert((extent<int[2][4], 1>::value) == 4);
assert((extent<int[][4], 1>::value) == 4);
```

— *end example*]

20.561.1 Relationships between types [meta.rel]

1 This sub-clause contains templates that may be used to query relationships between types at compile time.

2

Each of these templates shall be a BinaryTypeTrait (20.450.1) with a BaseCharacteristic of `true_type` if the corresponding condition is true, otherwise `false_type`.

Table 51 — Type relationship predicates

Template	Condition	Comments
`template <class T, class U>` `struct is_same;`	`T` and `U` name the same type with the same cv-qualifications	
`template <class Base, class Derived>` `struct is_base_of;`	`Base` is a base class of `Derived` (Clause 10) without regard to cv-qualifiers or `Base` and `Derived` are not unions and name the same class type without regard to cv-qualifiers	If `Base` and `Derived` are non-union class types and are different types (ignoring possible cv-qualifiers) then `Derived` shall be a complete type. [*Note:* Base classes that are private, protected, or ambiguous are, nonetheless, base classes. — *end note*]
`template <class From, class To>` `struct is_convertible;`	*see below*	`From` and `To` shall be complete types, arrays of unknown bound, or (possibly cv-qualified) `void` types.

1 [*Example:*

```
struct B {};
struct B1 : B {};
struct B2 : B {};
struct D : private B1, private B2 {};

is_base_of<B, D>::value          // true
is_base_of<const B, D>::value    // true
is_base_of<B, const D>::value    // true
is_base_of<B, const B>::value    // true
is_base_of<D, B>::value          // false
```

```
is_base_of<B&, D&>::value        // false
is_base_of<B[3], D[3]>::value    // false
is_base_of<int, int>::value      // false
```

— *end example*]

2

Given the following function prototype:

```
template <class T>
  add_rvalue_reference_t<T> create() noexcept;
```

the predicate condition for a template specialization `is_convertible<From, To>` shall be satisfied if and only if the return expression in the following code would be well-formed, including any implicit conversions to the return type of the function:

```
To test() {
  return create<From>();
}
```

[*Note:* This requirement gives well defined results for reference types, void types, array types, and function types. — *end note*] Access checking is performed as if in a context unrelated to `To` and `From`. Only the validity of the immediate context of the expression of the *return-statement* (including conversions to the return type) is considered. [*Note:* The evaluation of the conversion can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]

20.570.1 Transformations between types [meta.trans]

1 This sub-clause contains templates that may be used to transform one type to another following some predefined rule.

2 Each of the templates in this subclause shall be a *TransformationTrait* (20.450.1).

20.570.1.1 Const-volatile modifications [meta.trans.cv]

Table 52 — Const-volatile modifications

Template	Comments
`template <class T>` `struct remove_const;`	The member typedef `type` shall name the same type as `T` except that any top-level const-qualifier has been removed. [*Example:* `remove_const_t<const volatile int>` evaluates to `volatile int`, whereas `remove_const_t<const int*>` evaluates to `const int*`. — *end example*]
`template <class T>` `struct remove_volatile;`	The member typedef `type` shall name the same type as `T` except that any top-level volatile-qualifier has been removed. [*Example:* `remove_volatile_t<const volatile int>` evaluates to `const int`, whereas `remove_volatile_t<volatile int*>` evaluates to `volatile int*`. — *end example*]
`template <class T>` `struct remove_cv;`	The member typedef `type` shall be the same as `T` except that any top-level cv-qualifier has been removed. [*Example:* `remove_cv_t<const volatile int>` evaluates to `int`, whereas `remove_cv_t<const volatile int*>` evaluates to `const volatile int*`. — *end example*]

Table 52 — Const-volatile modifications (continued)

Template	Comments
`template <class T>` `struct add_const;`	If `T` is a reference, function, or top-level const-qualified type, then `type` shall name the same type as `T`, otherwise `T const`.
`template <class T>` `struct add_volatile;`	If `T` is a reference, function, or top-level volatile-qualified type, then `type` shall name the same type as `T`, otherwise `T volatile`.
`template <class T>` `struct add_cv;`	The member typedef `type` shall name the same type as `add_const_t<add_volatile_t<T>>`.

20.570.1.2 Reference modifications [meta.trans.ref]

Table 53 — Reference modifications

Template	Comments
`template <class T>` `struct remove_reference;`	If `T` has type "reference to `T1`" then the member typedef `type` shall name `T1`; otherwise, `type` shall name `T`.

`template <class T>`
`struct`
`add_lvalue_reference;`
	If `T` names an object or function type then the member typedef `type` shall name `T&`; otherwise, if `T` names a type "rvalue reference to `T1`" then the member typedef `type` shall name `T1&`; otherwise, `type` shall name `T`.

`template <class T>`
`struct`
`add_rvalue_reference;`
	If `T` names an object or function type then the member typedef `type` shall name `T&&`; otherwise, `type` shall name `T`. [*Note:* This rule reflects the semantics of reference collapsing (8.97.1). For example, when a type `T` names a type `T1&`, the type `add_rvalue_reference_t<T>` is not an rvalue reference. — *end note*]

20.570.1.3 Sign modifications [meta.trans.sign]

Table 54 — Sign modifications

Template	Comments
`template <class T>` `struct make_signed;`	If `T` names a (possibly cv-qualified) signed integer type (3.3151.1) then the member typedef `type` shall name the type `T`; otherwise, if `T` names a (possibly cv-qualified) unsigned integer type then `type` shall name the corresponding signed integer type, with the same cv-qualifiers as `T`; otherwise, `type` shall name the signed integer type with smallest rank (4.807) for which `sizeof(T) == sizeof(type)`, with the same cv-qualifiers as `T`. *Requires:* `T` shall be a (possibly cv-qualified) integral type or enumeration but not a `bool` type.
`template <class T>` `struct make_unsigned;`	If `T` names a (possibly cv-qualified) unsigned integer type (3.3151.1) then the member typedef `type` shall name the type `T`; otherwise, if `T` names a (possibly cv-qualified) signed integer type then `type` shall name the corresponding unsigned integer type, with the same cv-qualifiers as `T`; otherwise, `type` shall name the unsigned integer type with smallest rank (4.807) for which `sizeof(T) == sizeof(type)`, with the same cv-qualifiers as `T`. *Requires:* `T` shall be a (possibly cv-qualified) integral type or enumeration but not a `bool` type.

20.570.1.4 Array modifications [meta.trans.arr]

Table 55 — Array modifications

Template	Comments
`template <class T>` `struct remove_extent;`	If `T` names a type "array of `U`", the member typedef `type` shall be `U`, otherwise `T`. [*Note:* For multidimensional arrays, only the first array dimension is removed. For a type "array of `const U`", the resulting type is `const U`. — *end note*]
`template <class T>` `struct remove_all_extents;`	If `T` is "multi-dimensional array of `U`", the resulting member typedef `type` is `U`, otherwise `T`.

1 [*Example*

```
// the following assertions hold:
assert((is_same<remove_extent_t<int>, int>::value));
assert((is_same<remove_extent_t<int[2]>, int>::value));
assert((is_same<remove_extent_t<int[2][3]>, int[3]>::value));
assert((is_same<remove_extent_t<int[][3]>, int[3]>::value));
```

— *end example*]

2 [*Example*

```
// the following assertions hold:
assert((is_same<remove_all_extents_t<int>, int>::value));
assert((is_same<remove_all_extents_t<int[2]>, int>::value));
assert((is_same<remove_all_extents_t<int[2][3]>, int>::value));
assert((is_same<remove_all_extents_t<int[][3]>, int>::value));
```

— *end example*]

20.570.1.5 Pointer modifications [meta.trans.ptr]

Table 56 — Pointer modifications

Template	Comments
`template <class T>` `struct remove_pointer;`	If `T` has type "(possibly cv-qualified) pointer to `T1`" then the member typedef `type` shall name `T1`; otherwise, it shall name `T`.
`template <class T>` `struct add_pointer;`	The member typedef `type` shall name the same type as `remove_reference_t<T>*`.

20.570.1.6 Other transformations [meta.trans.other]

Table 57 — Other transformations

Template	Condition	Comments
`template <std::size_t Len, std::size_t Align = default-alignment> struct aligned_storage;`	`Len` shall not be zero. `Align` shall be equal to `alignof(T)` for some type `T` or to *default-alignment*.	The value of *default-alignment* shall be the most stringent alignment requirement for any C++ object type whose size is no greater than `Len` (3.2955). The member typedef `type` shall be a POD type suitable for use as uninitialized storage for any object whose size is at most *Len* and whose alignment is a divisor of *Align*.
`template <std::size_t Len, class... Types> struct aligned_union;`	At least one type is provided.	The member typedef `type` shall be a POD type suitable for use as uninitialized storage for any object whose type is listed in `Types`; its size shall be at least `Len`. The static member `alignment_value` shall be an integral constant of type `std::size_t` whose value is the strictest alignment of all types listed in `Types`.
`template <class T> struct decay;`		Let `U` be `remove_reference_t<T>`. If `is_array<U>::value` is `true`, the member typedef `type` shall equal `remove_extent_t<U>*`. If `is_function<U>::value` is `true`, the member typedef `type` shall equal `add_pointer_t<U>`. Otherwise the member typedef `type` equals `remove_cv_t<U>`. [*Note:* This behavior is similar to the lvalue-to-rvalue (4.127), array-to-pointer (4.180), and function-to-pointer (4.220) conversions applied when an lvalue expression is used as an rvalue, but also strips *cv*-qualifiers from class types in order to more closely model by-value argument passing. — *end note*]
`template <bool B, class T = void> struct enable_if;`		If `B` is `true`, the member typedef `type` shall equal `T`; otherwise, there shall be no member `type`.
`template <bool B, class T, class F> struct conditional;`		If `B` is `true`, the member typedef `type` shall equal `T`. If `B` is `false`, the member typedef `type` shall equal `F`.

Table 57 — Other transformations (continued)

Template	Condition	Comments
`template <class... T>` `struct common_type;`		The member typedef `type` shall be defined as set out below. All types in the parameter pack `T` shall be complete or (possibly *cv*) `void`. A program may specialize this trait if at least one template parameter in the specialization is a user-defined type. [*Note:* Such specializations are needed when only explicit conversions are desired among the template arguments. — *end note*]
`template <class T>` `struct underlying_type;`	`T` shall be an enumeration type (7.1001)	The member typedef `type` shall name the underlying type of `T`.

`template <class Fn,`
`class... ArgTypes> struct`
`result_of<Fn(ArgTypes...)>;`
	`Fn` and all types in the parameter pack `ArgTypes` shall be complete types, (possibly cv-qualified) `void`, or arrays of unknown bound.	If the expression `INVOKE(declval<Fn>(), declval<ArgTypes>()...)` is well formed when treated as an unevaluated operand (Clause 5), the member typedef `type` shall name the type `decltype(INVOKE(declval<Fn>(), declval<ArgTypes>()...));` otherwise, there shall be no member `type`. Access checking is performed as if in a context unrelated to `Fn` and `ArgTypes`. Only the validity of the immediate context of the expression is considered. [*Note:* The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]

1

[*Note:* A typical implementation would define `aligned_storage` as:

```
template <std::size_t Len, std::size_t Alignment>
struct aligned_storage {
  typedef struct {
    alignas(Alignment) unsigned char __data[Len];
  } type;
};
```

— *end note*]

1

It is implementation-defined whether any extended alignment is supported (3.3924).

1

The nested typedef `common_type::type` shall be defined as follows:

```
template <class ...T> struct common_type;

template <class T>
struct common_type<T> {
  typedef decay_t<T> type;
};

template <class T, class U>
struct common_type<T, U> {
  typedef decay_t<decltype(true ? declval<T>() : declval<U>())> type;
};

template <class T, class U, class... V>
struct common_type<T, U, V...> {
  typedef common_type_t<common_type_t<T, U>, V...> type;
};
```

1 [*Example:* Given these definitions:

```
typedef bool (&PF1)();
typedef short (*PF2)(long);

struct S {
  operator PF2() const;
  double operator()(char, int&);
  void fn(long) const;
  char data;
};

typedef void (S::*PMF)(long) const;
typedef char S::*PMD;
```

the following assertions will hold:

```
static_assert(is_same<result_of_t<S(int)>, short>::value, "Error!");
static_assert(is_same<result_of_t<S&(unsigned char, int&)>, double>::value, "Error!");
static_assert(is_same<result_of_t<PF1()>, bool>::value, "Error!");
static_assert(is_same<result_of_t<PMF(unique_ptr<S>, int)>, void>::value, "Error!");
static_assert(is_same<result_of_t<PMD(S)>, char&&>::value, "Error!");
static_assert(is_same<result_of_t<PMD(const S*)>, const char&>::value, "Error!");
```

— *end example*]

20.575 Compile-time rational arithmetic [ratio]

20.575.1 In general [ratio.general]

1

This subclause describes the ratio library. It provides a class template `ratio` which exactly represents any finite rational number with a numerator and denominator representable by compile-time constants of type `intmax_t`.

1 Throughout this subclause, the names of template parameters are used to express type requirements. If a template parameter is named `R1` or `R2`, and the template argument is not a specialization of the `ratio` template, the program is ill-formed.

20.576.1 Header `<ratio>` synopsis [ratio.syn]

```
namespace std {
  // 20.576.2, class template ratio
  template <intmax_t N, intmax_t D = 1> class ratio;

  // 20.576.3, ratio arithmetic
  template <class R1, class R2> using ratio_add = see below;
  template <class R1, class R2> using ratio_subtract = see below;
  template <class R1, class R2> using ratio_multiply = see below;
  template <class R1, class R2> using ratio_divide = see below;

  // 20.577.1, ratio comparison
  template <class R1, class R2> struct ratio_equal;
  template <class R1, class R2> struct ratio_not_equal;
  template <class R1, class R2> struct ratio_less;
  template <class R1, class R2> struct ratio_less_equal;
  template <class R1, class R2> struct ratio_greater;
  template <class R1, class R2> struct ratio_greater_equal;

  // 20.577.2, convenience SI typedefs
  typedef ratio<1, 1'000'000'000'000'000'000'000'000> yocto;  // see below
  typedef ratio<1,     1'000'000'000'000'000'000'000> zepto;  // see below
  typedef ratio<1,         1'000'000'000'000'000'000> atto;
  typedef ratio<1,             1'000'000'000'000'000> femto;
  typedef ratio<1,                 1'000'000'000'000> pico;
  typedef ratio<1,                     1'000'000'000> nano;
  typedef ratio<1,                         1'000'000> micro;
  typedef ratio<1,                             1'000> milli;
  typedef ratio<1,                               100> centi;
  typedef ratio<1,                                10> deci;
  typedef ratio<                               10, 1> deca;
  typedef ratio<                              100, 1> hecto;
  typedef ratio<                            1'000, 1> kilo;
  typedef ratio<                        1'000'000, 1> mega;
  typedef ratio<                    1'000'000'000, 1> giga;
  typedef ratio<                1'000'000'000'000, 1> tera;
  typedef ratio<            1'000'000'000'000'000, 1> peta;
  typedef ratio<        1'000'000'000'000'000'000, 1> exa;
  typedef ratio<    1'000'000'000'000'000'000'000, 1> zetta;  // see below
  typedef ratio<1'000'000'000'000'000'000'000'000, 1> yotta;  // see below
}
```

20.576.2 Class template `ratio` [ratio.ratio]

```
namespace std {
  template <intmax_t N, intmax_t D = 1>
  class ratio {
```

```
  public:
    static constexpr intmax_t num;
    static constexpr intmax_t den;
    typedef ratio<num, den> type;
  };
}
```

1 If the template argument `D` is zero or the absolute values of either of the template arguments `N` and `D` is not representable by type `intmax_t`, the program is ill-formed. [*Note:* These rules ensure that infinite ratios are avoided and that for any negative input, there exists a representable value of its absolute value which is positive. In a two's complement representation, this excludes the most negative value. — *end note*]

2 The static data members `num` and `den` shall have the following values, where `gcd` represents the greatest common divisor of the absolute values of `N` and `D`:

(2.1) — `num` shall have the value `sign(N) * sign(D) * abs(N) / gcd`.

(2.2) — `den` shall have the value `abs(D) / gcd`.

20.576.3 Arithmetic on `ratios` [ratio.arithmetic]

1 Each of the alias templates `ratio_add`, `ratio_subtract`, `ratio_multiply`, and `ratio_divide` denotes the result of an arithmetic computation on two `ratios` `R1` and `R2`. With `X` and `Y` computed (in the absence of arithmetic overflow) as specified by Table 58, each alias denotes a `ratio<U, V>` such that `U` is the same as `ratio<X, Y>::num` and `V` is the same as `ratio<X, Y>::den`.

2

If it is not possible to represent `U` or `V` with `intmax_t`, the program is ill-formed. Otherwise, an implementation should yield correct values of `U` and `V`. If it is not possible to represent `X` or `Y` with `intmax_t`, the program is ill-formed unless the implementation yields correct values of `U` and `V`.

Table 58 — Expressions used to perform ratio arithmetic

Type	Value of `X`	Value of `Y`
`ratio_add<R1, R2>`	`R1::num * R2::den + R2::num * R1::den`	`R1::den * R2::den`
`ratio_subtract<R1, R2>`	`R1::num * R2::den - R2::num * R1::den`	`R1::den * R2::den`
`ratio_multiply<R1, R2>`	`R1::num * R2::num`	`R1::den * R2::den`
`ratio_divide<R1, R2>`	`R1::num * R2::den`	`R1::den * R2::num`

1 [*Example:*

```
static_assert(ratio_add<ratio<1,3>, ratio<1,6>>::num == 1, "1/3+1/6 == 1/2");
static_assert(ratio_add<ratio<1,3>, ratio<1,6>>::den == 2, "1/3+1/6 == 1/2");
static_assert(ratio_multiply<ratio<1,3>, ratio<3,2>>::num == 1, "1/3*3/2 == 1/2");
static_assert(ratio_multiply<ratio<1,3>, ratio<3,2>>::den == 2, "1/3*3/2 == 1/2");

  // The following cases may cause the program to be ill-formed under some implementations
static_assert(ratio_add<ratio<1,INT_MAX>, ratio<1,INT_MAX>>::num == 2,
  "1/MAX+1/MAX == 2/MAX");
static_assert(ratio_add<ratio<1,INT_MAX>, ratio<1,INT_MAX>>::den == INT_MAX,
  "1/MAX+1/MAX == 2/MAX");
static_assert(ratio_multiply<ratio<1,INT_MAX>, ratio<INT_MAX,2>>::num == 1,
  "1/MAX * MAX/2 == 1/2");
static_assert(ratio_multiply<ratio<1,INT_MAX>, ratio<INT_MAX,2>>::den == 2,
```

```
"1/MAX * MAX/2 == 1/2");
```

— *end example*]

20.577.1 Comparison of ratios [ratio.comparison]

```
template <class R1, class R2> struct ratio_equal
  : integral_constant<bool, see below> { };
```

1 If `R1::num == R2::num` and `R1::den == R2::den`, `ratio_equal<R1, R2>` shall be derived from `integral_constant<bool, true>`; otherwise it shall be derived from `integral_constant<bool, false>`.

```
template <class R1, class R2> struct ratio_not_equal
  : integral_constant<bool, !ratio_equal<R1, R2>::value> { };

template <class R1, class R2> struct ratio_less
  : integral_constant<bool, see below> { };
```

2 If `R1::num * R2::den < R2::num * R1::den`, `ratio_less<R1, R2>` shall be derived from `integral_constant<bool, true>`; otherwise it shall be derived from `integral_constant<bool, false>`. Implementations may use other algorithms to compute this relationship to avoid overflow. If overflow occurs, the program is ill-formed.

```
template <class R1, class R2> struct ratio_less_equal
  : integral_constant<bool, !ratio_less<R2, R1>::value> { };

template <class R1, class R2> struct ratio_greater
  : integral_constant<bool, ratio_less<R2, R1>::value> { };

template <class R1, class R2> struct ratio_greater_equal
  : integral_constant<bool, !ratio_less<R1, R2>::value> { };
```

20.577.2 SI types for ratio [ratio.si]

1 For each of the typedefs `yocto`, `zepto`, `zetta`, and `yotta`, if both of the constants used in its specification are representable by `intmax_t`, the typedef shall be defined; if either of the constants is not representable by `intmax_t`, the typedef shall not be defined.

20.578 Time utilities [time]

20.578.1 In general [time.general]

1 This subclause describes the chrono library (20.578.2) and various C functions (20.605.1) that provide generally useful time utilities.

20.578.2 Header <chrono> synopsis [time.syn]

```
namespace std {
namespace chrono {

// 20.585.2, class template duration
template <class Rep, class Period = ratio<1> > class duration;

// 20.591.1, class template time_point
template <class Clock, class Duration = typename Clock::duration> class time_point;

}  // namespace chrono
```

```
// 20.585.1.3 common_type specializations
template <class Rep1, class Period1, class Rep2, class Period2>
  struct common_type<chrono::duration<Rep1, Period1>, chrono::duration<Rep2, Period2>>;

template <class Clock, class Duration1, class Duration2>
  struct common_type<chrono::time_point<Clock, Duration1>, chrono::time_point<Clock, Duration2>>;

namespace chrono {

// 20.585.1, customization traits
template <class Rep> struct treat_as_floating_point;
template <class Rep> struct duration_values;

// 20.589.0.4, duration arithmetic
template <class Rep1, class Period1, class Rep2, class Period2>
  common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
  constexpr operator+(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
template <class Rep1, class Period1, class Rep2, class Period2>
  common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
  constexpr operator-(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
template <class Rep1, class Period, class Rep2>
  duration<common_type_t<Rep1, Rep2>, Period>
  constexpr operator*(const duration<Rep1, Period>& d, const Rep2& s);
template <class Rep1, class Rep2, class Period>
  duration<common_type_t<Rep1, Rep2>, Period>
  constexpr operator*(const Rep1& s, const duration<Rep2, Period>& d);
template <class Rep1, class Period, class Rep2>
  duration<common_type_t<Rep1, Rep2>, Period>
  constexpr operator/(const duration<Rep1, Period>& d, const Rep2& s);
template <class Rep1, class Period1, class Rep2, class Period2>
  common_type_t<Rep1, Rep2>
  constexpr operator/(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
template <class Rep1, class Period, class Rep2>
  duration<common_type_t<Rep1, Rep2>, Period>
  constexpr operator%(const duration<Rep1, Period>& d, const Rep2& s);
template <class Rep1, class Period1, class Rep2, class Period2>
  common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
  constexpr operator%(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

// 20.589.0.5, duration comparisons
template <class Rep1, class Period1, class Rep2, class Period2>

constexpr chrono::nanoseconds                            operator "" ns(unsigned long long);
constexpr chrono::duration<unspecified , nano>           operator "" ns(long double);

}  // namespace chrono_literals
}  // namespace literals

namespace chrono {

using namespace literals::chrono_literals;

} // namespace chrono

}  // namespace std
```

20.578.3 Clock requirements [time.clock.req]

1 A clock is a bundle consisting of a `duration`, a `time_point`, and a function `now()` to get the current `time_point`. The origin of the clock's `time_point` is referred to as the clock's *epoch*. A clock shall meet the requirements in Table 59.

2

In Table 59 `C1` and `C2` denote clock types. `t1` and `t2` are values returned by `C1::now()` where the call returning `t1` happens before (1.859) the call returning `t2` and both of these calls occur before `C1::time_point::max()`. [*Note:* this means `C1` did not wrap around between `t1` and `t2`. — *end note*]

Table 59 — Clock requirements

Expression	Return type	Operational semantics
`C1::rep`	An arithmetic type or a class emulating an arithmetic type	The representation type of `C1::duration`.
`C1::period`	a specialization of `ratio`	The tick period of the clock in seconds.

Table 59 — Clock requirements (continued)

Expression	Return type	Operational semantics
`C1::duration`	`chrono::duration<C1::rep, C1::period>`	The `duration` type of the clock.
`C1::time_point`	`chrono::time_point<C1>` or `chrono::time_point<C2, C1::duration>`	The `time_point` type of the clock. `C1` and `C2` shall refer to the same epoch.
`C1::is_steady`	`const bool`	`true` if `t1 <= t2` is always `true` and the time between clock ticks is constant, otherwise `false`.
`C1::now()`	`C1::time_point`	Returns a `time_point` object representing the current point in time.

1

[*Note:* The relative difference in durations between those reported by a given clock and the SI definition is a measure of the quality of implementation. — *end note*]

1

A type `TC` meets the `TrivialClock` requirements if:

— `TC` satisfies the `Clock` requirements (20.578.3),

— the types `TC::rep`, `TC::duration`, and `TC::time_point` satisfy the requirements of `EqualityComparable` (Table 17), `LessThanComparable` (Table 18), `DefaultConstructible` (Table 19), `CopyConstructible` (Table 21), `CopyAssignable` (Table 23), `Destructible` (Table 24), and the requirements of numeric types (26.2). [*Note:* this means, in particular, that operations on these types will not throw exceptions. — *end note*]

— lvalues of the types `TC::rep`, `TC::duration`, and `TC::time_point` are swappable (17.143.0.1),

— the function `TC::now()` does not throw exceptions, and

— the type `TC::time_point::clock` meets the `TrivialClock` requirements, recursively.

20.585.1 Time-related traits [time.traits]

20.585.1.1 `treat_as_floating_point` [time.traits.is_fp]

```
template <class Rep> struct treat_as_floating_point
  : is_floating_point<Rep> { };
```

1 The `duration` template uses the `treat_as_floating_point` trait to help determine if a `duration` object can be converted to another `duration` with a different tick `period`. If `treat_as_floating_point<Rep>::value` is true, then implicit conversions are allowed among `durations`. Otherwise, the implicit convertibility depends on the tick `periods` of the `durations`. [*Note:* The intention of this trait is to indicate whether a given class behaves like a floating-point type, and thus allows division of one value by another with acceptable loss of precision. If `treat_as_floating_point<Rep>::value` is `false`, `Rep` will be treated as if it behaved like an integral type for the purpose of these conversions. — *end note*]

20.585.1.2 `duration_values` [time.traits.duration_values]

```
template <class Rep>
struct duration_values {
public:
  static constexpr Rep zero();
  static constexpr Rep min();
  static constexpr Rep max();
};
```

1 The `duration` template uses the `duration_values` trait to construct special values of the durations representation (`Rep`). This is done because the representation might be a class type with behavior which requires some other implementation to return these special values. In that case, the author of that class type should specialize `duration_values` to return the indicated values.

`static constexpr Rep zero();`

2 *Returns:* `Rep(0)`. [*Note:* `Rep(0)` is specified instead of `Rep()` because `Rep()` may have some other meaning, such as an uninitialized value. — *end note*]

3 *Remark:* The value returned shall be the additive identity.

`static constexpr Rep min();`

4 *Returns:* `numeric_limits<Rep>::lowest()`.

5 *Remark:* The value returned shall compare less than or equal to `zero()`.

`static constexpr Rep max();`

6 *Returns:* `numeric_limits<Rep>::max()`.

7 *Remark:* The value returned shall compare greater than `zero()`.

20.585.1.3 Specializations of `common_type` [time.traits.specializations]

```
template <class Rep1, class Period1, class Rep2, class Period2>
struct common_type<chrono::duration<Rep1, Period1>, chrono::duration<Rep2, Period2>> {
  typedef chrono::duration<common_type_t<Rep1, Rep2>, see below> type;
};
```

1 The `period` of the `duration` indicated by this specialization of `common_type` shall be the greatest common divisor of `Period1` and `Period2`. [*Note:* This can be computed by forming a ratio of the greatest common divisor of `Period1::num` and `Period2::num` and the least common multiple of `Period1::den` and `Period2::den`. — *end note*]

2 [*Note:* The `typedef` name `type` is a synonym for the `duration` with the largest tick `period` possible where both `duration` arguments will convert to it without requiring a division operation. The representation of this type is intended to be able to hold any value resulting from this conversion with no truncation error, although floating-point durations may have round-off errors. — *end note*]

```
template <class Clock, class Duration1, class Duration2>
struct common_type<chrono::time_point<Clock, Duration1>, chrono::time_point<Clock, Duration2>> {
  typedef chrono::time_point<Clock, common_type_t<Duration1, Duration2>> type;
};
```

3 The common type of two `time_point` types is a `time_point` with the same clock as the two types and the common type of their two `durations`.

20.585.2 Class template `duration` [time.duration]

1 A `duration` type measures time between two points in time (`time_points`). A `duration` has a representation which holds a count of ticks and a tick period. The tick period is the amount of time which occurs from one tick to the next, in units of seconds. It is expressed as a rational constant using the template `ratio`.

```
template <class Rep, class Period = ratio<1>>
class duration {
public:
  typedef Rep    rep;
  typedef Period period;
private:
  rep rep_;  // exposition only
public:
  // 20.587.0.1, construct/copy/destroy:
  constexpr duration() = default;
  template <class Rep2>
      constexpr explicit duration(const Rep2& r);
  template <class Rep2, class Period2>
     constexpr duration(const duration<Rep2, Period2>& d);
  ~duration() = default;
  duration(const duration&) = default;
  duration& operator=(const duration&) = default;

  // 20.589.0.1, observer:
  constexpr rep count() const;

  // 20.589.0.2, arithmetic:
  constexpr duration  operator+() const;
  constexpr duration  operator-() const;
  duration& operator++();
  duration  operator++(int);
  duration& operator--();
  duration  operator--(int);

  duration& operator+=(const duration& d);
  duration& operator-=(const duration& d);

  duration& operator*=(const rep& rhs);
  duration& operator/=(const rep& rhs);
  duration& operator%=(const rep& rhs);
  duration& operator%=(const duration& rhs);

  // 20.589.0.3, special values:
  static constexpr duration zero();
  static constexpr duration min();
  static constexpr duration max();
};
```

2 *Requires:* `Rep` shall be an arithmetic type or a class emulating an arithmetic type.

3 *Remarks:* If `duration` is instantiated with a `duration` type for the template argument `Rep`, the program is ill-formed.

4

Remarks: If `Period` is not a specialization of `ratio`, the program is ill-formed.

1 *Remarks:* If `Period::num` is not positive, the program is ill-formed.

2 *Requires:* Members of `duration` shall not throw exceptions other than those thrown by the indicated operations on their representations.

3

Remarks: The defaulted copy constructor of duration shall be a `constexpr` function if and only if the required initialization of the member `rep_` for copy and move, respectively, would satisfy the requirements for a `constexpr` function.

[*Example:*

```
duration<long, ratio<60>> d0;        // holds a count of minutes using a long
duration<long long, milli> d1;       // holds a count of milliseconds using a long long
duration<double, ratio<1, 30>>  d2;  // holds a count with a tick period of 1/30 of a second
                                     // (30 Hz) using a double
```

— *end example*]

20.587.0.1 `duration` constructors [time.duration.cons]

```
template <class Rep2>
  constexpr explicit duration(const Rep2& r);
```

1

Remarks: This constructor shall not participate in overload resolution unless `Rep2` is implicitly convertible to `rep` and

— `treat_as_floating_point<rep>::value` is `true` or

— `treat_as_floating_point<Rep2>::value` is `false`.

[*Example:*

```
duration<int, milli> d(3);          // OK
duration<int, milli> d(3.5);        // error
```

— *end example*]

1 *Effects:* Constructs an object of type `duration`.

2 *Postcondition:* `count() == static_cast<rep>(r)`.

```
template <class Rep2, class Period2>
  constexpr duration(const duration<Rep2, Period2>& d);
```

3 *Remarks:* This constructor shall not participate in overload resolution unless no overflow is induced in the conversion and `treat_as_floating_point<rep>::value` is `true` or both `ratio_divide<Period2, period>::den` is `1` and `treat_as_floating_point<Rep2>::value` is `false`. [*Note:* This requirement prevents implicit truncation error when converting between integral-based `duration` types. Such a construction could easily lead to confusion about the value of the `duration`. — *end note*] [*Example:*

```
duration<int, milli> ms(3);
duration<int, micro> us = ms;       // OK
duration<int, milli> ms2 = us;      // error
```

— *end example*]

4

Effects: Constructs an object of type `duration`, constructing `rep_` from `duration_cast<duration>(d).count()`.

20.589.0.1 `duration` observer [time.duration.observer]

```
constexpr rep count() const;
```

1 *Returns:* `rep_`.

20.589.0.2 duration arithmetic [time.duration.arithmetic]

`constexpr duration operator+() const;`

1 *Returns:* `*this`.

`constexpr duration operator-() const;`

2 *Returns:* `duration(-rep_);`.

`duration& operator++();`

3 *Effects:* `++rep_`.

4 *Returns:* `*this`.

`duration operator++(int);`

5 *Returns:* `duration(rep_++);`.

`duration& operator--();`

6 *Effects:* `--rep_`.

7 *Returns:* `*this`.

`duration operator--(int);`

8 *Returns:* `duration(rep_--);`.

`duration& operator+=(const duration& d);`

9 *Effects:* `rep_ += d.count()`.

10 *Returns:* `*this`.

`duration& operator-=(const duration& d);`

11 *Effects:* `rep_ -= d.count()`.

12 *Returns:* `*this`.

`duration& operator*=(const rep& rhs);`

13 *Effects:* `rep_ *= rhs`.

14 *Returns:* `*this`.

`duration& operator/=(const rep& rhs);`

15 *Effects:* `rep_ /= rhs`.

16 *Returns:* `*this`.

`duration& operator%=(const rep& rhs);`

17 *Effects:* `rep_ %= rhs`.

18 *Returns:* `*this`.

`duration& operator%=(const duration& rhs);`

19 *Effects:* `rep_ %= rhs.count()`.

20 *Returns:* `*this`.

20.589.0.3 duration special values [time.duration.special]

```
static constexpr duration zero();
```

1 *Returns:* `duration(duration_values<rep>::zero())`.

```
static constexpr duration min();
```

2 *Returns:* `duration(duration_values<rep>::min())`.

```
static constexpr duration max();
```

3 *Returns:* `duration(duration_values<rep>::max())`.

20.589.0.4 duration non-member arithmetic [time.duration.nonmember]

1 In the function descriptions that follow, `CD` represents the return type of the function. `CR(A,B)` represents `common_type_t<A, B>`.

```
template <class Rep1, class Period1, class Rep2, class Period2>
  constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
  operator+(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
```

2 *Returns:* CD(CD(lhs).count() + CD(rhs).count()).

```
template <class Rep1, class Period1, class Rep2, class Period2>
  constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
  operator-(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
```

3 *Returns:* CD(CD(lhs).count() - CD(rhs).count()).

```
template <class Rep1, class Period, class Rep2>
  constexpr duration<common_type_t<Rep1, Rep2>, Period>
  operator*(const duration<Rep1, Period>& d, const Rep2& s);
```

4 *Remarks:* This operator shall not participate in overload resolution unless `Rep2` is implicitly convertible to `CR(Rep1, Rep2)`.

5 *Returns:* CD(CD(d).count() * s).

```
template <class Rep1, class Rep2, class Period>
  constexpr duration<common_type_t<Rep1, Rep2>, Period>
  operator*(const Rep1& s, const duration<Rep2, Period>& d);
```

6 *Remarks:* This operator shall not participate in overload resolution unless `Rep1` is implicitly convertible to `CR(Rep1, Rep2)`.

7 *Returns:* `d * s`.

```
template <class Rep1, class Period, class Rep2>
  constexpr duration<common_type_t<Rep1, Rep2>, Period>
  operator/(const duration<Rep1, Period>& d, const Rep2& s);
```

8 *Remarks:* This operator shall not participate in overload resolution unless `Rep2` is implicitly convertible to `CR(Rep1, Rep2)` and `Rep2` is not an instantiation of `duration`.

9 *Returns:* CD(CD(d).count() / s).

```
template <class Rep1, class Period1, class Rep2, class Period2>
  constexpr common_type_t<Rep1, Rep2>
  operator/(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
```

10 *Returns:* `CD(lhs).count() / CD(rhs).count()`.

```
template <class Rep1, class Period, class Rep2>
  constexpr duration<common_type_t<Rep1, Rep2>, Period>
  operator%(const duration<Rep1, Period>& d, const Rep2& s);
```

11 *Remarks:* This operator shall not participate in overload resolution unless `Rep2` is implicitly convertible to `CR(Rep1, Rep2)` and `Rep2` is not an instantiation of `duration`.

12 *Returns:* CD(CD(d).count() % s).

```
template <class Rep1, class Period1, class Rep2, class Period2>
  constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
  operator%(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
```

13 *Returns:* CD(CD(lhs).count() % CD(rhs).count()).

20.589.0.5 `duration` comparisons [time.duration.comparisons]

1 In the function descriptions that follow, `CT` represents `common_type_t<A, B>`, where `A` and `B` are the types of the two arguments to the function.

```
template <class Rep1, class Period1, class Rep2, class Period2>
  constexpr bool operator==(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
```

2 *Returns:* `CT(lhs).count() == CT(rhs).count()`.

```
template <class Rep1, class Period1, class Rep2, class Period2>
  constexpr bool operator!=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
```

3 *Returns:* `!(lhs == rhs)`.

```
template <class Rep1, class Period1, class Rep2, class Period2>
  constexpr bool operator<(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
```

4 *Returns:* `CT(lhs).count() < CT(rhs).count()`.

```
template <class Rep1, class Period1, class Rep2, class Period2>
  constexpr bool operator<=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
```

5 *Returns:* `!(rhs < lhs)`.

```
template <class Rep1, class Period1, class Rep2, class Period2>
  constexpr bool operator>(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
```

6 *Returns:* `rhs < lhs`.

```
template <class Rep1, class Period1, class Rep2, class Period2>
  constexpr bool operator>=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
```

7 *Returns:* `!(lhs < rhs)`.

20.589.0.6 `duration_cast` [time.duration.cast]

```
template <class ToDuration, class Rep, class Period>
  constexpr ToDuration duration_cast(const duration<Rep, Period>& d);
```

1

Remarks: This function shall not participate in overload resolution unless `ToDuration` is an instantiation of `duration`.

1 *Returns:* Let `CF` be `ratio_divide<Period, typename ToDuration::period>`, and `CR` be `common_type< typename ToDuration::rep, Rep, intmax_t>::type`.

(1.1) — If `CF::num == 1` and `CF::den == 1`, returns

```
ToDuration(static_cast<typename ToDuration::rep>(d.count()))
```

(1.2) — otherwise, if `CF::num != 1` and `CF::den == 1`, returns

```
ToDuration(static_cast<typename ToDuration::rep>(
  static_cast<CR>(d.count()) * static_cast<CR>(CF::num)))
```

(1.3) — otherwise, if `CF::num == 1` and `CF::den != 1`, returns

```
ToDuration(static_cast<typename ToDuration::rep>(
  static_cast<CR>(d.count()) / static_cast<CR>(CF::den)))
```

(1.4) — otherwise, returns

```
ToDuration(static_cast<typename ToDuration::rep>(
  static_cast<CR>(d.count()) * static_cast<CR>(CF::num) / static_cast<CR>(CF::den)))
```

Notes: This function does not use any implicit conversions; all conversions are done with `static_cast`. It avoids multiplications and divisions when it is known at compile time that one or more arguments is 1. Intermediate computations are carried out in the widest representation and only converted to the destination representation at the final step.

20.591.0.1 Suffixes for duration literals [time.duration.literals]

1 This section describes literal suffixes for constructing duration literals. The suffixes `h`, `min`, `s`, `ms`, `us`, `ns` denote duration values of the corresponding types `hours`, `minutes`, `seconds`, `milliseconds`, `microseconds`, and `nanoseconds` respectively if they are applied to integral literals.

2 If any of these suffixes are applied to a floating point literal the result is a `chrono::duration` literal with an unspecified floating point representation.

3 If any of these suffixes are applied to an integer literal and the resulting `chrono::duration` value cannot be represented in the result type because of overflow, the program is ill-formed.

4 [*Example:* The following code shows some duration literals.

```
using namespace std::chrono_literals;
auto constexpr aday=24h;
auto constexpr lesson=45min;
auto constexpr halfanhour=0.5h;
```

— *end example*]

```
constexpr chrono::hours                                operator "" h(unsigned long long hours);
constexpr chrono::duration<unspecified , ratio<3600,1>> operator "" h(long double hours);
```

5 *Returns:* A `duration` literal representing `hours` hours.

```
constexpr chrono::minutes                             operator "" min(unsigned long long minutes);
constexpr chrono::duration<unspecified , ratio<60,1>> operator "" min(long double minutes);
```

6 *Returns:* A `duration` literal representing `minutes` minutes.

```
constexpr chrono::seconds                operator "" s(unsigned long long sec);
constexpr chrono::duration<unspecified > operator "" s(long double sec);
```

7 *Returns:* A `duration` literal representing `sec` seconds.

8 [*Note:* The same suffix `s` is used for `basic_string` but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. — *end note*]

```
constexpr chrono::milliseconds                  operator "" ms(unsigned long long msec);
constexpr chrono::duration<unspecified , milli> operator "" ms(long double msec);
```

9 *Returns:* A `duration` literal representing `msec` milliseconds.

```
constexpr chrono::microseconds                  operator "" us(unsigned long long usec);
constexpr chrono::duration<unspecified , micro> operator "" us(long double usec);
```

10 *Returns:* A `duration` literal representing `usec` microseconds.

```
constexpr chrono::nanoseconds                  operator "" ns(unsigned long long nsec);
constexpr chrono::duration<unspecified , nano> operator "" ns(long double nsec);
```

11 *Returns:* A `duration` literal representing `nsec` nanoseconds.

20.591.1 Class template `time_point` [time.point]

```
template <class Clock, class Duration = typename Clock::duration>
class time_point {
public:
  typedef Clock                     clock;
  typedef Duration                  duration;
  typedef typename duration::rep    rep;
  typedef typename duration::period period;
private:
  duration d_;  // exposition only

public:
  // 20.591.1.1, construct:
  constexpr time_point();  // has value epoch
  constexpr explicit time_point(const duration& d);  // same as time_point() + d
  template <class Duration2>
    constexpr time_point(const time_point<clock, Duration2>& t);

  // 20.591.1.2, observer:
  constexpr duration time_since_epoch() const;

  // 20.591.1.3, arithmetic:
  time_point& operator+=(const duration& d);
  time_point& operator-=(const duration& d);

  // 20.591.1.4, special values:
  static constexpr time_point min();
  static constexpr time_point max();
};
```

1 `Clock` shall meet the Clock requirements (20.591.2).

2 If `Duration` is not an instance of `duration`, the program is ill-formed.

20.591.1.1 `time_point` constructors [time.point.cons]

```
constexpr time_point();
```

1 *Effects:* Constructs an object of type `time_point`, initializing `d_` with `duration::zero()`. Such a `time_point` object represents the epoch.

```
constexpr explicit time_point(const duration& d);
```

2 *Effects:* Constructs an object of type `time_point`, initializing `d_` with `d`. Such a `time_point` object represents the epoch `+ d`.

```
template <class Duration2>
  constexpr time_point(const time_point<clock, Duration2>& t);
```

3 *Remarks:* This constructor shall not participate in overload resolution unless `Duration2` is implicitly convertible to `duration`.

4 *Effects:* Constructs an object of type `time_point`, initializing `d_` with `t.time_since_epoch()`.

20.591.1.2 `time_point` observer [time.point.observer]

```
constexpr duration time_since_epoch() const;
```

1 *Returns:* `d_`.

20.591.1.3 `time_point` arithmetic [time.point.arithmetic]

```
time_point& operator+=(const duration& d);
```

1 *Effects:* `d_ += d`.

2 *Returns:* `*this`.

```
time_point& operator-=(const duration& d);
```

3 *Effects:* `d_ -= d`.

4 *Returns:* `*this`.

20.591.1.4 `time_point` special values [time.point.special]

```
static constexpr time_point min();
```

1 *Returns:* `time_point(duration::min())`.

```
static constexpr time_point max();
```

2 *Returns:* `time_point(duration::max())`.

20.591.1.5 `time_point` non-member arithmetic [time.point.nonmember]

```
template <class Clock, class Duration1, class Rep2, class Period2>
  constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>>
  operator+(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
```

1 *Returns:* `CT(lhs.time_since_epoch() + rhs)`, where `CT` is the type of the return value.

```
template <class Rep1, class Period1, class Clock, class Duration2>
  constexpr time_point<Clock, common_type_t<duration<Rep1, Period1>, Duration2>>
  operator+(const duration<Rep1, Period1>& lhs, const time_point<Clock, Duration2>& rhs);
```

2 *Returns:* `rhs + lhs`.

```
template <class Clock, class Duration1, class Rep2, class Period2>
  constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>>
  operator-(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
```

3 *Returns:* `lhs + (-rhs)`.

```
template <class Clock, class Duration1, class Duration2>
  constexpr common_type_t<Duration1, Duration2>
  operator-(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
```

4 *Returns:* `lhs.time_since_epoch() - rhs.time_since_epoch()`.

20.591.1.6 `time_point` comparisons [time.point.comparisons]

```
template <class Clock, class Duration1, class Duration2>
  constexpr bool operator==(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
```

1 *Returns:* `lhs.time_since_epoch() == rhs.time_since_epoch()`.

```
template <class Clock, class Duration1, class Duration2>
  constexpr bool operator!=(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
```

2 *Returns:* `!(lhs == rhs)`.

```
template <class Clock, class Duration1, class Duration2>
  constexpr bool operator<(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
```

3 *Returns:* `lhs.time_since_epoch() < rhs.time_since_epoch()`.

```
template <class Clock, class Duration1, class Duration2>
  constexpr bool operator<=(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
```

4 *Returns:* `!(rhs < lhs)`.

```
template <class Clock, class Duration1, class Duration2>
  constexpr bool operator>(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
```

5 *Returns:* `rhs < lhs`.

```
template <class Clock, class Duration1, class Duration2>
  constexpr bool operator>=(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
```

6 *Returns:* `!(lhs < rhs)`.

20.591.1.7 `time_point_cast` [time.point.cast]

```
template <class ToDuration, class Clock, class Duration>
  constexpr time_point<Clock, ToDuration>
  time_point_cast(const time_point<Clock, Duration>& t);
```

1 *Remarks:* This function shall not participate in overload resolution unless `ToDuration` is an instantiation of `duration`.

2 *Returns:* `time_point<Clock, ToDuration>(duration_cast<ToDuration>(t.time_since_epoch()))`.

20.591.2 Clocks [time.clock]

1 The types defined in this subclause shall satisfy the `TrivialClock` requirements (20.578.3).

20.591.2.1 Class `system_clock` [time.clock.system]

1

Objects of class `system_clock` represent wall clock time from the system-wide realtime clock.

```
class system_clock {
public:
  typedef see below                          rep;
  typedef ratio<unspecified , unspecified >   period;
  typedef chrono::duration<rep, period>      duration;
  typedef chrono::time_point<system_clock>   time_point;
  static constexpr bool is_steady =        unspecified;

  static time_point now() noexcept;
```

```
  // Map to C API
  static time_t      to_time_t  (const time_point& t) noexcept;
  static time_point  from_time_t(time_t t) noexcept;
};
```

`typedef unspecified system_clock::rep;`

1 *Requires:* `system_clock::duration::min() < system_clock::duration::zero()` shall be `true`. [*Note:* This implies that `rep` is a signed type. — *end note*]

`static time_t to_time_t(const time_point& t) noexcept;`

2 *Returns:* A `time_t` object that represents the same point in time as `t` when both values are restricted to the coarser of the precisions of `time_t` and `time_point`. It is implementation defined whether values are rounded or truncated to the required precision.

`static time_point from_time_t(time_t t) noexcept;`

3 *Returns:* A `time_point` object that represents the same point in time as `t` when both values are restricted to the coarser of the precisions of `time_t` and `time_point`. It is implementation defined whether values are rounded or truncated to the required precision.

20.595.0.1 Class `steady_clock` [time.clock.steady]

1

Objects of class `steady_clock` represent clocks for which values of `time_point` never decrease as physical time advances and for which values of `time_point` advance at a steady rate relative to real time. That is, the clock may not be adjusted.

```
class steady_clock {
public:
  typedef unspecified                                rep;
  typedef ratio<unspecified , unspecified >          period;
  typedef chrono::duration<rep, period>              duration;
  typedef chrono::time_point<unspecified, duration>  time_point;
  static constexpr bool is_steady =               true;

  static time_point now() noexcept;
};
```

20.600.0.1 Class `high_resolution_clock` [time.clock.hires]

1

Objects of class `high_resolution_clock` represent clocks with the shortest tick period. `high_resolution_clock` may be a synonym for `system_clock` or `steady_clock`.

```
class high_resolution_clock {
public:
  typedef unspecified                                rep;
  typedef ratio<unspecified , unspecified >          period;
  typedef chrono::duration<rep, period>              duration;
  typedef chrono::time_point<unspecified , duration> time_point;
  static constexpr bool is_steady =               unspecified ;

  static time_point now() noexcept;
};
```

20.605.1 Date and time functions [date.time]

1 Table 60 describes the header `<ctime>`.

Table 60 — Header `<ctime>` synopsis

Type	Name(s)			
Macros:	`NULL`	`CLOCKS_PER_SEC`		
Types:	`size_t`	`clock_t`	`time_t`	
Struct:	`tm`			
Functions:				
`asctime`	`clock`	`difftime`	`localtime`	`strftime`
`ctime`	`gmtime`	`mktime`	`time`	

2 The contents are the same as the Standard C library header `<time.h>`.[231] The functions `asctime`, `ctime`, `gmtime`, and `localtime` are not required to avoid data races (17.607.0.1).

See also: ISO C Clause 7.12, Amendment 1 Clause 4.6.4.

20.606 Class template `scoped_allocator_adaptor` [allocator.adaptor]

20.606.1 Header `<scoped_allocator>` synopsis [allocator.adaptor.syn]

```
// scoped allocator adaptor
template <class OuterAlloc, class... InnerAlloc>
  class scoped_allocator_adaptor;
template <class OuterA1, class OuterA2, class... InnerAllocs>
  bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                  const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
template <class OuterA1, class OuterA2, class... InnerAllocs>
  bool operator!=(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                  const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
```

1

The class template `scoped_allocator_adaptor` is an allocator template that specifies the memory resource (the outer allocator) to be used by a container (as any other allocator does) and also specifies an inner allocator resource to be passed to the constructor of every element within the container. This adaptor is instantiated with one outer and zero or more inner allocator types. If instantiated with only one allocator type, the inner allocator becomes the `scoped_allocator_adaptor` itself, thus using the same allocator resource for the container and every element within the container and, if the elements themselves are containers, each of their elements recursively. If instantiated with more than one allocator, the first allocator is the outer allocator for use by the container, the second allocator is passed to the constructors of the container's elements, and, if the elements themselves are containers, the third allocator is passed to the elements' elements, and so on. If containers are nested to a depth greater than the number of allocators, the last allocator is used repeatedly, as in the single-allocator case, for any remaining recursions. [*Note:* The `scoped_allocator_adaptor` is derived from the outer allocator type so it can be substituted for the outer allocator type in most expressions. — *end note*]

```
namespace std {
  template <class OuterAlloc, class... InnerAllocs>
    class scoped_allocator_adaptor : public OuterAlloc {
  private:
    typedef allocator_traits<OuterAlloc> OuterTraits; // exposition only
```

231) `strftime` supports the C conversion specifiers `C`, `D`, `e`, `F`, `g`, `G`, `h`, `r`, `R`, `t`, `T`, `u`, `V`, and `z`, and the modifiers `E` and `O`.

```
  scoped_allocator_adaptor<InnerAllocs...> inner;    // exposition only
public:
  typedef OuterAlloc outer_allocator_type;
  typedef see below inner_allocator_type;

  typedef typename OuterTraits::value_type value_type;
  typedef typename OuterTraits::size_type size_type;
  typedef typename OuterTraits::difference_type difference_type;
  typedef typename OuterTraits::pointer pointer;
  typedef typename OuterTraits::const_pointer const_pointer;
  typedef typename OuterTraits::void_pointer void_pointer;
  typedef typename OuterTraits::const_void_pointer const_void_pointer;

  typedef see below propagate_on_container_copy_assignment;
  typedef see below propagate_on_container_move_assignment;
  typedef see below propagate_on_container_swap;

  template <class Tp>
    struct rebind {
      typedef scoped_allocator_adaptor<
        OuterTraits::template rebind_alloc<Tp>, InnerAllocs...> other;
    };

  scoped_allocator_adaptor();
  template <class OuterA2>
    scoped_allocator_adaptor(OuterA2&& outerAlloc,
                             const InnerAllocs&... innerAllocs) noexcept;

  scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;
  scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;

  template <class OuterA2>
    scoped_allocator_adaptor(
      const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& other) noexcept;
  template <class OuterA2>
    scoped_allocator_adaptor(
      scoped_allocator_adaptor<OuterA2, InnerAllocs...>&& other) noexcept;

  ~scoped_allocator_adaptor();

  inner_allocator_type& inner_allocator() noexcept;
  const inner_allocator_type& inner_allocator() const noexcept;
  outer_allocator_type& outer_allocator() noexcept;
  const outer_allocator_type& outer_allocator() const noexcept;

  pointer allocate(size_type n);
  pointer allocate(size_type n, const_void_pointer hint);
  void deallocate(pointer p, size_type n);
  size_type max_size() const;

  template <class T, class... Args>
    void construct(T* p, Args&&... args);
  template <class T1, class T2, class... Args1, class... Args2>
    void construct(pair<T1, T2>* p, piecewise_construct_t,
                   tuple<Args1...> x, tuple<Args2...> y);
```

```
    template <class T1, class T2>
      void construct(pair<T1, T2>* p);
    template <class T1, class T2, class U, class V>
      void construct(pair<T1, T2>* p, U&& x, V&& y);
    template <class T1, class T2, class U, class V>
      void construct(pair<T1, T2>* p, const pair<U, V>& x);
    template <class T1, class T2, class U, class V>
      void construct(pair<T1, T2>* p, pair<U, V>&& x);

    template <class T>
      void destroy(T* p);

    scoped_allocator_adaptor select_on_container_copy_construction() const;
  };

  template <class OuterA1, class OuterA2, class... InnerAllocs>
    bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                    const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
  template <class OuterA1, class OuterA2, class... InnerAllocs>
    bool operator!=(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                    const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
}
```

20.608.1 Scoped allocator adaptor member types [allocator.adaptor.types]

`typedef` *see below* `inner_allocator_type;`

1 *Type:* `scoped_allocator_adaptor<OuterAlloc>` if `sizeof...(InnerAllocs)` is zero; otherwise, `scoped_allocator_adaptor<InnerAllocs...>`.

`typedef` *see below* `propagate_on_container_copy_assignment;`

2 *Type:* `true_type` if `allocator_traits<A>::propagate_on_container_copy_assignment::value` is `true` for any `A` in the set of `OuterAlloc` and `InnerAllocs...`; otherwise, `false_type`.

`typedef` *see below* `propagate_on_container_move_assignment;`

3 *Type:* `true_type` if `allocator_traits<A>::propagate_on_container_move_assignment::value` is `true` for any `A` in the set of `OuterAlloc` and `InnerAllocs...`; otherwise, `false_type`.

`typedef` *see below* `propagate_on_container_swap;`

4 *Type:* `true_type` if `allocator_traits<A>::propagate_on_container_swap::value` is `true` for any `A` in the set of `OuterAlloc` and `InnerAllocs...`; otherwise, `false_type`.

20.608.2 Scoped allocator adaptor constructors [allocator.adaptor.cnstr]

`scoped_allocator_adaptor();`

1

Effects: value-initializes the `OuterAlloc` base class and the `inner` allocator object.

```
template <class OuterA2>
  scoped_allocator_adaptor(OuterA2&& outerAlloc,
                           const InnerAllocs&... innerAllocs) noexcept;
```

1 *Requires:* `OuterAlloc` shall be constructible from `OuterA2`.

2 *Effects:* initializes the `OuterAlloc` base class with `std::forward<OuterA2>(outerAlloc)` and `inner` with `innerAllocs...` (hence recursively initializing each allocator within the adaptor with the corresponding allocator from the argument list).

```
scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;
```

3 *Effects:* initializes each allocator within the adaptor with the corresponding allocator from `other`.

```
scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;
```

4 *Effects:* move constructs each allocator within the adaptor with the corresponding allocator from `other`.

```
template <class OuterA2>
  scoped_allocator_adaptor(const scoped_allocator_adaptor<OuterA2,
                                                          InnerAllocs...>& other) noexcept;
```

5 *Requires:* `OuterAlloc` shall be constructible from `OuterA2`.

6 *Effects:* initializes each allocator within the adaptor with the corresponding allocator from `other`.

```
template <class OuterA2>
  scoped_allocator_adaptor(scoped_allocator_adaptor<OuterA2,
                                                    InnerAllocs...>&& other) noexcept;
```

7 *Requires:* `OuterAlloc` shall be constructible from `OuterA2`.

8 *Effects:* initializes each allocator within the adaptor with the corresponding allocator rvalue from `other`.

20.609.1 Scoped allocator adaptor members [allocator.adaptor.members]

1 In the `construct` member functions, *OUTERMOST(x)* is `x` if `x` does not have an `outer_allocator()` member function and *OUTERMOST(x.outer_allocator())* otherwise; *OUTERMOST_ALLOC_TRAITS(x)* is `allocator_traits<decltype(`*OUTERMOST*`(x))>`. [*Note:* *OUTERMOST*(x) and *OUTERMOST_ALLOC_TRAITS*(x) are recursive operations. It is incumbent upon the definition of `outer_allocator()` to ensure that the recursion terminates. It will terminate for all instantiations of `scoped_allocator_adaptor`. — *end note*]

```
inner_allocator_type& inner_allocator() noexcept;
const inner_allocator_type& inner_allocator() const noexcept;
```

2 *Returns:* `*this` if `sizeof...(InnerAllocs)` is zero; otherwise, `inner`.

```
outer_allocator_type& outer_allocator() noexcept;
```

3 *Returns:* `static_cast<OuterAlloc&>(*this)`.

```
const outer_allocator_type& outer_allocator() const noexcept;
```

4 *Returns:* `static_cast<const OuterAlloc&>(*this)`.

```
pointer allocate(size_type n);
```

5 *Returns:* `allocator_traits<OuterAlloc>::allocate(outer_allocator(), n)`.

```
pointer allocate(size_type n, const_void_pointer hint);
```

6 *Returns:* `allocator_traits<OuterAlloc>::allocate(outer_allocator(), n, hint)`.

```
void deallocate(pointer p, size_type n) noexcept;
```

7 *Effects:* `allocator_traits<OuterAlloc>::deallocate(outer_allocator(), p, n)`;

```
size_type max_size() const;
```

8 *Returns:* `allocator_traits<OuterAlloc>::max_size(outer_allocator())`.

```
template <class T, class... Args>
  void construct(T* p, Args&&... args);
```

9 *Effects:*

(9.1) — If `uses_allocator<T, inner_allocator_type>::value` is `false` and `is_constructible<T, Args...>::value` is `true`, calls *OUTERMOST_ALLOC_TRAITS*(`*this`)`::construct(`*`OUTERMOST`*`(*this), p, std::forward<Args>(args)...)`.

(9.2) — Otherwise, if `uses_allocator<T, inner_allocator_type>::value` is `true` and `is_constructible<T, allocator_arg_t, inner_allocator_type, Args...>::value` is `true`, calls *OUTERMOST_ALLOC_TRAITS*(`*this`)`::construct(`*`OUTERMOST`*`(*this), p, allocator_arg, inner_allocator(), std::forward<Args>(args)...)`.

(9.3) — Otherwise, if `uses_allocator<T, inner_allocator_type>::value` is `true` and `is_constructible<T, Args..., inner_allocator_type>::value` is `true`, calls *OUTERMOST_ALLOC_TRAITS*(*this):: `construct(`*`OUTERMOST`*`(*this), p, std::forward<Args>(args)..., inner_allocator())`.

(9.4) — Otherwise, the program is ill-formed. [*Note:* An error will result if `uses_allocator` evaluates to true but the specific constructor does not take an allocator. This definition prevents a silent failure to pass an inner allocator to a contained element. — *end note*]

```
template <class T1, class T2, class... Args1, class... Args2>
  void construct(pair<T1, T2>* p,piecewise_construct_t,
                 tuple<Args1...> x, tuple<Args2...> y);
```

10 *Requires:* all of the types in `Args1` and `Args2` shall be `CopyConstructible` (Table 21).

11 *Effects:* Constructs a `tuple` object `xprime` from `x` by the following rules:

(11.1) — If `uses_allocator<T1, inner_allocator_type>::value` is `false` and `is_constructible<T1, Args1...>::value` is `true`, then `xprime` is `x`.

(11.2) — Otherwise, if `uses_allocator<T1, inner_allocator_type>::value` is `true` and `is_constructible<T1, allocator_arg_t, inner_allocator_type, Args1...>::value` is `true`, then `xprime` is `tuple_cat(tuple<allocator_arg_t, inner_allocator_type&>( allocator_arg, inner_allocator()), std::move(x))`.

(11.3) — Otherwise, if `uses_allocator<T1, inner_allocator_type>::value` is `true` and `is_constructible<T1, Args1..., inner_allocator_type>::value` is `true`, then `xprime` is `tuple_cat(std::move(x), tuple<inner_allocator_type&>(inner_allocator()))`.

(11.4) — Otherwise, the program is ill-formed.

and constructs a `tuple` object `yprime` from `y` by the following rules:

(11.5) — If `uses_allocator<T2, inner_allocator_type>::value` is `false` and `is_constructible<T2, Args2...>::value` is `true`, then `yprime` is `y`.

(11.6) — Otherwise, if `uses_allocator<T2, inner_allocator_type>::value` is `true` and `is_constructible<T2, allocator_arg_t, inner_allocator_type, Args2...>::value` is `true`, then `yprime` is `tuple_cat(tuple<allocator_arg_t, inner_allocator_type&>( allocator_arg, inner_allocator()), std::move(y))`.

(11.7) — Otherwise, if `uses_allocator<T2, inner_allocator_type>::value` is `true` and `is_constructible<T2, Args2..., inner_allocator_type>::value` is `true`, then `yprime` is `tuple_cat(std::move(y), tuple<inner_allocator_type&>(inner_allocator()))`.

(11.8) — Otherwise, the program is ill-formed.

then calls *`OUTERMOST_ALLOC_TRAITS`*`(*this)::construct(`*`OUTERMOST`*`(*this), p, piecewise_construct, std::move(xprime), std::move(yprime))`.

```
template <class T1, class T2>
  void construct(pair<T1, T2>* p);
```

12 *Effects:* Equivalent to `this->construct(p, piecewise_construct, tuple<>(), tuple<>())`.

```
template <class T1, class T2, class U, class V>
  void construct(pair<T1, T2>* p, U&& x, V&& y);
```

13 *Effects:* Equivalent to `this->construct(p, piecewise_construct, forward_as_tuple(std::forward<U>(x)), forward_as_tuple(std::forward<V>(y)))`.

```
template <class T1, class T2, class U, class V>
  void construct(pair<T1, T2>* p, const pair<U, V>& x);
```

14 *Effects:* Equivalent to `this->construct(p, piecewise_construct, forward_as_tuple(x.first), forward_as_tuple(x.second))`.

```
template <class T1, class T2, class U, class V>
  void construct(pair<T1, T2>* p, pair<U, V>&& x);
```

15 *Effects:* Equivalent to `this->construct(p, piecewise_construct, forward_as_tuple(std::forward<U>(x.first)), forward_as_tuple(std::forward<V>(x.second)))`.

```
template <class T>
  void destroy(T* p);
```

16 *Effects:* calls *`OUTERMOST_ALLOC_TRAITS`*`(*this)::destroy(`*`OUTERMOST`*`(*this), p)`.

```
scoped_allocator_adaptor select_on_container_copy_construction() const;
```

17 *Returns:* A new scoped_allocator_adaptor object where each allocator `A` in the adaptor is initialized from the result of calling `allocator_traits<A>::select_on_container_copy_construction()` on the corresponding allocator in `*this`.

20.609.2 Scoped allocator operators [scoped.adaptor.operators]

```
template <class OuterA1, class OuterA2, class... InnerAllocs>
  bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                  const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
```

1 *Returns:* `a.outer_allocator() == b.outer_allocator()` if `sizeof...(InnerAllocs)` is zero; otherwise, `a.outer_allocator() == b.outer_allocator() && a.inner_allocator() == b.inner_allocator()`.

```
template <class OuterA1, class OuterA2, class... InnerAllocs>
  bool operator!=(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                  const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
```

2 *Returns:* `!(a == b)`.

20.610 Class type_index [type.index]

20.610.1 Header <typeindex> synopsis [type.index.synopsis]

```
namespace std {
  class type_index;
  template <class T> struct hash;
  template<> struct hash<type_index>;
}
```

20.610.2 type_index overview [type.index.overview]

```
namespace std {
  class type_index {
  public:
    type_index(const type_info& rhs) noexcept;
    bool operator==(const type_index& rhs) const noexcept;
    bool operator!=(const type_index& rhs) const noexcept;
    bool operator< (const type_index& rhs) const noexcept;
    bool operator<= (const type_index& rhs) const noexcept;
    bool operator> (const type_index& rhs) const noexcept;
    bool operator>= (const type_index& rhs) const noexcept;
    size_t hash_code() const noexcept;
    const char* name() const noexcept;
  private:
    const type_info* target;     // exposition only
    // Note that the use of a pointer here, rather than a reference,
    // means that the default copy/move constructor and assignment
    // operators will be provided and work as expected.
  };
}
```

1 The class `type_index` provides a simple wrapper for `type_info` which can be used as an index type in associative containers (23.894) and in unordered associative containers (23.932).

20.610.3 type_index members [type.index.members]

`type_index(const type_info& rhs) noexcept;`

1 *Effects:* constructs a `type_index` object, the equivalent of `target = &rhs`.

`bool operator==(const type_index& rhs) const noexcept;`

2 *Returns:* `*target == *rhs.target`

`bool operator!=(const type_index& rhs) const noexcept;`

3 *Returns:* `*target != *rhs.target`

`bool operator<(const type_index& rhs) const noexcept;`

4 *Returns:* `target->before(*rhs.target)`

`bool operator<=(const type_index& rhs) const noexcept;`

5 *Returns:* `!rhs.target->before(*target)`

`bool operator>(const type_index& rhs) const noexcept;`

6 *Returns:* `rhs.target->before(*target)`

```
bool operator>=(const type_index& rhs) const noexcept;
```

7 *Returns:* `!target->before(*rhs.target)`

```
size_t hash_code() const noexcept;
```

1 *Returns:* `target->hash_code()`

```
const char* name() const noexcept;
```

2 *Returns:* `target->name()`

20.611.1 Hash support [type.index.hash]

```
template <> struct hash<type_index>;
```

1 The template specialization shall meet the requirements of class template `hash` (20.443.1). For an object `index` of type `type_index`, `hash<type_index>()(index)` shall evaluate to the same result as `index.hash_code()`.

21 Strings library [strings]

21.1 General [strings.general]

1

This Clause describes components for manipulating sequences of any non-array POD (3.2955) type. In this Clause such types are called *char-like types* , and objects of char-like types are called *char-like objects* or simply *characters*.

1 The following subclauses describe a character traits class, a string class, and null-terminated sequence utilities, as summarized in Table 61.

Table 61 — Strings library summary

Subclause		Header(s)
21.7	Character traits	`<string>`
21.26	String classes	`<string>`

21.261	Null-terminated sequence utilities	`<cctype>`
		`<cwctype>`
		`<cstring>`
		`<cwchar>`
		`<cstdlib>`
		`<cuchar>`

21.7 Character traits [char.traits]

1 This subclause defines requirements on classes representing *character traits*, and defines a class template `char_traits<charT>`, along with four specializations, `char_traits<char>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`, that satisfy those requirements.

2 Most classes specified in Clauses 21.26 and 27 need a set of related types and functions to complete the definition of their semantics. These types and functions are provided as a set of member typedefs and functions in the template parameter 'traits' used by each such template. This subclause defines the semantics of these members.

3 To specialize those templates to generate a string or iostream class to handle a particular character container type `CharT`, that and its related character traits class `Traits` are passed as a pair of parameters to the string or iostream template as parameters `charT` and `traits`. `Traits::char_type` shall be the same as `CharT`.

4 This subclause specifies a struct template, `char_traits<charT>`, and four explicit specializations of it, `char_traits<char>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`, all of which appear in the header `<string>` and satisfy the requirements below.

21.7.1 Character traits requirements [char.traits.require]

1

In Table 62, `X` denotes a Traits class defining types and functions for the character container type `CharT`; `c` and `d` denote values of type `CharT`; `p` and `q` denote values of type `const CharT*`; `s` denotes a value of type `CharT*`; `n`, `i` and `j` denote values of type `std::size_t`; `e` and `f` denote values of type `X::int_type`; `pos` denotes a value of type `X::pos_type`; `state` denotes a value of type `X::state_type`; and `r` denotes an lvalue of type `CharT`. Operations on Traits shall not throw exceptions.

Table 62 — Character traits requirements

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`X::char_type`	`charT`	(described in 21.17.1)	compile-time
`X::int_type`		(described in 21.17.1)	compile-time
`X::off_type`		(described in 21.17.1)	compile-time
`X::pos_type`		(described in 21.17.1)	compile-time
`X::state_type`		(described in 21.17.1)	compile-time
`X::eq(c,d)`	`bool`	yields: whether `c` is to be treated as equal to `d`.	constant
`X::lt(c,d)`	`bool`	yields: whether `c` is to be treated as less than `d`.	constant
`X::compare(p,q,n)`	`int`	yields: `0` if for each `i` in `[0,n)`, `X::eq(p[i],q[i])` is true; else, a negative value if, for some `j` in `[0,n)`, `X::lt(p[j],q[j])` is true and for each `i` in `[0,j)` `X::eq(p[i],q[i])` is true; else a positive value.	linear
`X::length(p)`	`std::size_t`	yields: the smallest `i` such that `X::eq(p[i],charT())` is true.	linear
`X::find(p,n,c)`	`const X::char_type*`	yields: the smallest `q` in `[p,p+n)` such that `X::eq(*q,c)` is true, zero otherwise.	linear
`X::move(s,p,n)`	`X::char_type*`	for each `i` in `[0,n)`, performs `X::assign(s[i],p[i])`. Copies correctly even where the ranges `[p,p+n)` and `[s,s+n)` overlap. yields: `s`.	linear
`X::copy(s,p,n)`	`X::char_type*`	pre: `p` not in `[s,s+n)`. yields: `s`. for each `i` in `[0,n)`, performs `X::assign(s[i],p[i])`.	linear
`X::assign(r,d)`	(not used)	assigns `r=d`.	constant
`X::assign(s,n,c)`	`X::char_type*`	for each `i` in `[0,n)`, performs `X::assign(s[i],c)`. yields: `s`.	linear
`X::not_eof(e)`	`int_type`	yields: `e` if `X::eq_int_type(e,X::eof())` is false, otherwise a value `f` such that `X::eq_int_type(f,X::eof())` is false.	constant
`X::to_char_type(e)`	`X::char_type`	yields: if for some `c`, `X::eq_int_type(e,X::to_int_type(c))` is true, `c`; else some unspecified value.	constant

Table 62 — Character traits requirements (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`X::to_int_type(c)`	`X::int_type`	yields: some value `e`, constrained by the definitions of `to_char_type` and `eq_int_type`.	constant
`X::eq_int_type(e,f)`	`bool`	yields: for all `c` and `d`, `X::eq(c,d)` is equal to `X::eq_int_type(X::to_int_type(c), X::to_int_type(d))`; otherwise, yields true if `e` and `f` are both copies of `X::eof()`; otherwise, yields false if one of `e` and `f` is a copy of `X::eof()` and the other is not; otherwise the value is unspecified.	constant
`X::eof()`	`X::int_type`	yields: a value `e` such that `X::eq_int_type(e,X::to_int_type(c))` is false for all values `c`.	constant

1 The struct template

```
template<class charT> struct char_traits;
```

shall be provided in the header `<string>` as a basis for explicit specializations.

21.17.1 traits typedefs [char.traits.typedefs]

```
typedef CHAR_T char_type;
```

1 The type `char_type` is used to refer to the character container type in the implementation of the library classes defined in 21.26 and Clause 27.

```
typedef INT_T int_type;
```

2 *Requires:* For a certain character container type `char_type`, a related container type `INT_T` shall be a type or class which can represent all of the valid characters converted from the corresponding `char_type` values, as well as an end-of-file value, `eof()`. The type `int_type` represents a character container type which can hold end-of-file to be used as a return type of the iostream class member functions.[232]

```
typedef implementation-defined off_type;
typedef implementation-defined pos_type;
```

1 *Requires:* Requirements for `off_type` and `pos_type` are described in 27.2.2 and 27.16.

```
typedef STATE_T state_type;
```

232) If `eof()` can be held in `char_type` then some iostreams operations may give surprising results.

2

Requires: `state_type` shall meet the requirements of `CopyAssignable` (Table 23), `CopyConstructible` (Table 21), and `DefaultConstructible` (Table 19) types.

21.21.1 `char_traits` specializations [char.traits.specializations]

```
namespace std {
  template<> struct char_traits<char>;
  template<> struct char_traits<char16_t>;
  template<> struct char_traits<char32_t>;
  template<> struct char_traits<wchar_t>;
}
```

1 The header `<string>` shall define four specializations of the template struct `char_traits`: `char_traits<char>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`.

2 The requirements for the members of these specializations are given in Clause 21.7.1.

21.21.1.1 `struct char_traits<char>` [char.traits.specializations.char]

```
namespace std {
  template<> struct char_traits<char> {
    typedef char        char_type;
    typedef int         int_type;
    typedef streamoff   off_type;
    typedef streampos   pos_type;
    typedef mbstate_t   state_type;

    static void assign(char_type& c1, const char_type& c2) noexcept;
    static constexpr bool eq(char_type c1, char_type c2) noexcept;
    static constexpr bool lt(char_type c1, char_type c2) noexcept;

    static int compare(const char_type* s1, const char_type* s2, size_t n);
    static size_t length(const char_type* s);
    static const char_type* find(const char_type* s, size_t n,
                 const char_type& a);
    static char_type* move(char_type* s1, const char_type* s2, size_t n);
    static char_type* copy(char_type* s1, const char_type* s2, size_t n);
    static char_type* assign(char_type* s, size_t n, char_type a);

    static constexpr int_type not_eof(int_type c) noexcept;
    static constexpr char_type to_char_type(int_type c) noexcept;
    static constexpr int_type to_int_type(char_type c) noexcept;
    static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
    static constexpr int_type eof() noexcept;
  };
}
```

1 The defined types for `int_type`, `pos_type`, `off_type`, and `state_type` shall be `int`, `streampos`, `streamoff`, and `mbstate_t` respectively.

2 The type `streampos` shall be an implementation-defined type that satisfies the requirements for `pos_type` in 27.2.2 and 27.16.

3 The type `streamoff` shall be an implementation-defined type that satisfies the requirements for `off_type` in 27.2.2 and 27.16.

4

The type `mbstate_t` is defined in `<cwchar>` and can represent any of the conversion states that can occur in an implementation-defined set of supported multibyte character encoding rules.

1

The two-argument member `assign` shall be defined identically to the built-in operator `=`. The two-argument members `eq` and `lt` shall be defined identically to the built-in operators `==` and `<` for type `unsigned char`.

1 The member `eof()` shall return `EOF`.

21.24.0.1 `struct char_traits<char16_t>` [char.traits.specializations.char16_t]

```
namespace std {
  template<> struct char_traits<char16_t> {
    typedef char16_t        char_type;
    typedef uint_least16_t  int_type;
    typedef streamoff       off_type;
    typedef u16streampos    pos_type;
    typedef mbstate_t       state_type;

    static void assign(char_type& c1, const char_type& c2) noexcept;
    static constexpr bool eq(char_type c1, char_type c2) noexcept;
    static constexpr bool lt(char_type c1, char_type c2) noexcept;

    static int compare(const char_type* s1, const char_type* s2, size_t n);
    static size_t length(const char_type* s);
    static const char_type* find(const char_type* s, size_t n,
                                 const char_type& a);
    static char_type* move(char_type* s1, const char_type* s2, size_t n);
    static char_type* copy(char_type* s1, const char_type* s2, size_t n);
    static char_type* assign(char_type* s, size_t n, char_type a);

    static constexpr int_type not_eof(int_type c) noexcept;
    static constexpr char_type to_char_type(int_type c) noexcept;
    static constexpr int_type to_int_type(char_type c) noexcept;
    static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
    static constexpr int_type eof() noexcept;
  };
}
```

1 The type `u16streampos` shall be an implementation-defined type that satisfies the requirements for pos_type in 27.2.2 and 27.16.

2 The two-argument members `assign`, `eq`, and `lt` shall be defined identically to the built-in operators `=`, `==`, and `<` respectively.

3

The member `eof()` shall return an implementation-defined constant that cannot appear as a valid UTF-16 code unit.

21.25.0.1 `struct char_traits<char32_t>` [char.traits.specializations.char32_t]

```
namespace std {
  template<> struct char_traits<char32_t> {
    typedef char32_t        char_type;
    typedef uint_least32_t  int_type;
    typedef streamoff       off_type;
    typedef u32streampos    pos_type;
    typedef mbstate_t       state_type;
```

```
    static void assign(char_type& c1, const char_type& c2) noexcept;
    static constexpr bool eq(char_type c1, char_type c2) noexcept;
    static constexpr bool lt(char_type c1, char_type c2) noexcept;

    static int compare(const char_type* s1, const char_type* s2, size_t n);
    static size_t length(const char_type* s);
    static const char_type* find(const char_type* s, size_t n,
                 const char_type& a);
    static char_type* move(char_type* s1, const char_type* s2, size_t n);
    static char_type* copy(char_type* s1, const char_type* s2, size_t n);
    static char_type* assign(char_type* s, size_t n, char_type a);

    static constexpr int_type not_eof(int_type c) noexcept;
    static constexpr char_type to_char_type(int_type c) noexcept;
    static constexpr int_type to_int_type(char_type c) noexcept;
    static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
    static constexpr int_type eof() noexcept;
  };
}
```

1 The type `u32streampos` shall be an implementation-defined type that satisfies the requirements for pos_type in 27.2.2 and 27.16.

2 The two-argument members `assign`, `eq`, and `lt` shall be defined identically to the built-in operators `=`, `==`, and `<` respectively.

3 The member `eof()` shall return an implementation-defined constant that cannot appear as a Unicode code point.

21.25.0.2 `struct char_traits<wchar_t>` [char.traits.specializations.wchar.t]

```
namespace std {
  template<> struct char_traits<wchar_t> {
    typedef wchar_t      char_type;
    typedef wint_t       int_type;
    typedef streamoff    off_type;
    typedef wstreampos   pos_type;
    typedef mbstate_t    state_type;

    static void assign(char_type& c1, const char_type& c2) noexcept;
    static constexpr bool eq(char_type c1, char_type c2) noexcept;
    static constexpr bool lt(char_type c1, char_type c2) noexcept;

    static int compare(const char_type* s1, const char_type* s2, size_t n);
    static size_t length(const char_type* s);
    static const char_type* find(const char_type* s, size_t n,
                 const char_type& a);
    static char_type* move(char_type* s1, const char_type* s2, size_t n);
    static char_type* copy(char_type* s1, const char_type* s2, size_t n);
    static char_type* assign(char_type* s, size_t n, char_type a);

    static constexpr int_type not_eof(int_type c) noexcept;
    static constexpr char_type to_char_type(int_type c) noexcept;
    static constexpr int_type to_int_type(char_type c) noexcept;
    static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
    static constexpr int_type eof() noexcept;
```

```
  };
}
```

1 The defined types for `int_type`, `pos_type`, and `state_type` shall be `wint_t`, `wstreampos`, and `mbstate_t` respectively.

2 The type `wstreampos` shall be an implementation-defined type that satisfies the requirements for pos_type in 27.2.2 and 27.16.

3 The type `mbstate_t` is defined in `<cwchar>` and can represent any of the conversion states that can occur in an implementation-defined set of supported multibyte character encoding rules.

4 The two-argument members `assign`, `eq`, and `lt` shall be defined identically to the built-in operators `=`, `==`, and `<` respectively.

5 The member `eof()` shall return `WEOF`.

21.26 String classes [string.classes]

1

The header `<string>` defines the `basic_string` class template for manipulating varying-length sequences of char-like objects and four typedefs, `string`, `u16string`, `u32string`, and `wstring`, that name the specializations `basic_string<char>`, `basic_string<char16_t>`, `basic_string<char32_t>`, and `basic_string<wchar_t>`, respectively.

Header `<string>` synopsis

```
#include <initializer_list>

namespace std {

  // 21.7, character traits:
  template<class charT> struct char_traits;
  template <> struct char_traits<char>;
  template <> struct char_traits<char16_t>;
  template <> struct char_traits<char32_t>;
  template <> struct char_traits<wchar_t>;

  // 21.28, basic_string:
  template<class charT, class traits = char_traits<charT>,
    class Allocator = allocator<charT> >
      class basic_string;

  template<class charT, class traits, class Allocator>
    basic_string<charT,traits,Allocator>
      operator+(const basic_string<charT,traits,Allocator>& lhs,
                const basic_string<charT,traits,Allocator>& rhs);
  template<class charT, class traits, class Allocator>
    basic_string<charT,traits,Allocator>
      operator+(basic_string<charT,traits,Allocator>&& lhs,
                const basic_string<charT,traits,Allocator>& rhs);
  template<class charT, class traits, class Allocator>
    basic_string<charT,traits,Allocator>
      operator+(const basic_string<charT,traits,Allocator>& lhs,
                basic_string<charT,traits,Allocator>&& rhs);
  template<class charT, class traits, class Allocator>
    basic_string<charT,traits,Allocator>
      operator+(basic_string<charT,traits,Allocator>&& lhs,
```

```
              basic_string<charT,traits,Allocator>&& rhs);
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(const charT* lhs,
              const basic_string<charT,traits,Allocator>& rhs);
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(const charT* lhs,
              basic_string<charT,traits,Allocator>&& rhs);

  string    operator "" s(const char* str, size_t len);
  u16string operator "" s(const char16_t* str, size_t len);
  u32string operator "" s(const char32_t* str, size_t len);
  wstring   operator "" s(const wchar_t* str, size_t len);

}
}
}
```

21.28 Class template `basic_string` [basic.string]

1

The class template `basic_string` describes objects that can store a sequence consisting of a varying number of arbitrary char-like objects with the first element of the sequence at position zero. Such a sequence is also called a "string" if the type of the char-like objects that it holds is clear from context. In the rest of this Clause, the type of the char-like objects held in a `basic_string` object is designated by `charT`.

1 The member functions of `basic_string` use an object of the `Allocator` class passed as a template parameter to allocate and free storage for the contained char-like objects.[233]

2

The iterators supported by `basic_string` are random access iterators (24.167.1).

1 In all cases, `size() <= capacity()`.

2 The functions described in this Clause can report two kinds of errors, each associated with an exception type:

(2.1) — a *length* error is associated with exceptions of type `length_error` (19.3.4);

(2.2) — an *out-of-range* error is associated with exceptions of type `out_of_range` (19.4.1).

```
namespace std {
  template<class charT, class traits = char_traits<charT>,
    class Allocator = allocator<charT> >
  class basic_string {
  public:
    // types:
    typedef          traits                                        traits_type;
    typedef typename traits::char_type                             value_type;
    typedef          Allocator                                     allocator_type;
    typedef typename allocator_traits<Allocator>::size_type        size_type;
    typedef typename allocator_traits<Allocator>::difference_type  difference_type;

    typedef value_type& reference;
    typedef const value_type&   const_reference;
```

233) `Allocator::value_type` must name the same type as `charT` (21.31.1).

```
typedef typename allocator_traits<Allocator>::pointer          pointer;
typedef typename allocator_traits<Allocator>::const_pointer    const_pointer;

typedef implementation-defined              iterator;       // See 23.2

  };
}
```

21.31.1 `basic_string` general requirements [string.require]

1

If any operation would cause `size()` to exceed `max_size()`, that operation shall throw an exception object of type `length_error`.

1 If any member function or operator of `basic_string` throws an exception, that function or operator shall have no other effect.

2 In every specialization `basic_string<charT, traits, Allocator>`, the type `allocator_traits<Allocator>::value_type` shall name the same type as `charT`. Every object of type `basic_string<charT, traits, Allocator>` shall use an object of type `Allocator` to allocate and free storage for the contained `charT` objects as needed. The `Allocator` object used shall be obtained as described in 23.2.1.

3

The char-like objects in a `basic_string` object shall be stored contiguously. That is, for any `basic_string` object `s`, the identity `&*(s.begin() + n) == &*s.begin() + n` shall hold for all values of `n` such that `0 <= n < s.size()`.

1

References, pointers, and iterators referring to the elements of a `basic_string` sequence may be invalidated by the following uses of that `basic_string` object:

— as an argument to any standard library function taking a reference to non-const `basic_string` as an argument.[234]

— Calling non-const member functions, except `operator[]`, `at`, `front`, `back`, `begin`, `rbegin`, `end`, and `rend`.

21.85.1 `basic_string` constructors and assignment operators [string.cons]

```
explicit basic_string(const Allocator& a);
```

1 *Effects:* Constructs an object of class `basic_string`. The postconditions of this function are indicated in Table 63.

Table 63 — `basic_string(const Allocator&)` effects

Element	Value
`data()`	a non-null pointer that is copyable and can have 0 added to it
`size()`	0
`capacity()`	an unspecified value

```
basic_string(const basic_string& str);
basic_string(basic_string&& str) noexcept;
```

1 *Effects:* Constructs an object of class `basic_string` as indicated in Table 64. In the second form, `str` is left in a valid state with an unspecified value.

Table 64 — `basic_string(const basic_string&)` effects

Element	Value
`data()`	points at the first element of an allocated copy of the array whose first element is pointed at by `str.data()`
`size()`	`str.size()`
`capacity()`	a value at least as large as `size()`

```
basic_string(const basic_string& str,
             size_type pos, size_type n = npos,
             const Allocator& a = Allocator());
```

1 *Requires:* `pos <= str.size()`

2 *Throws:* `out_of_range` if `pos > str.size()`.

3 *Effects:* Constructs an object of class `basic_string` and determines the effective length `rlen` of the initial string value as the smaller of `n` and `str.size() - pos`, as indicated in Table 65.

234) For example, as an argument to non-member functions `swap()` (21.217.1.8), `operator>>()` (21.217.1.9), and `getline()` (21.217.1.9), or as an argument to `basic_string::swap()`

Table 65 — `basic_string(const basic_string&, size_type, size_type, const Allocator&)` effects

Element	Value
`data()`	points at the first element of an allocated copy of `rlen` consecutive elements of the string controlled by `str` beginning at position `pos`
`size()`	`rlen`
`capacity()`	a value at least as large as `size()`

```
basic_string(const charT* s, size_type n,
             const Allocator& a = Allocator());
```

1

Requires: `s` points to an array of at least `n` elements of `charT`.

1 *Effects:* Constructs an object of class `basic_string` and determines its initial string value from the array of `charT` of length `n` whose first element is designated by `s`, as indicated in Table 66.

Table 66 — `basic_string(const charT*, size_type, const Allocator&)` effects

Element	Value
`data()`	points at the first element of an allocated copy of the array whose first element is pointed at by `s`
`size()`	`n`
`capacity()`	a value at least as large as `size()`

```
basic_string(const charT* s, const Allocator& a = Allocator());
```

2

Requires: `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

1

Effects: Constructs an object of class `basic_string` and determines its initial string value from the array of `charT` of length `traits::length(s)` whose first element is designated by `s`, as indicated in Table 67.

Table 67 — `basic_string(const charT*, const Allocator&)` effects

Element	Value
`data()`	points at the first element of an allocated copy of the array whose first element is pointed at by `s`
`size()`	`traits::length(s)`
`capacity()`	a value at least as large as `size()`

1 *Remarks:* Uses `traits::length()`.

```
basic_string(size_type n, charT c, const Allocator& a = Allocator());
```

2 *Requires:* `n < npos`

3 *Effects:* Constructs an object of class `basic_string` and determines its initial string value by repeating the char-like object `c` for all `n` elements, as indicated in Table 68.

Table 68 — `basic_string(size_t, charT, const Allocator&)` effects

Element	Value
`data()`	points at the first element of an allocated array of `n` elements, each storing the initial value `c`
`size()`	`n`
`capacity()`	a value at least as large as `size()`

```
template<class InputIterator>
  basic_string(InputIterator begin, InputIterator end,
               const Allocator& a = Allocator());
```

4 *Effects:* If `InputIterator` is an integral type, equivalent to

```
basic_string(static_cast<size_type>(begin), static_cast<value_type>(end), a)
```

5 Otherwise constructs a string from the values in the range [`begin`, `end`), as indicated in the Sequence Requirements table (see 23.224.1).

```
basic_string(initializer_list<charT> il, const Allocator& a = Allocator());
```

1 *Effects:* Same as `basic_string(il.begin(), il.end(), a)`.

```
basic_string(const basic_string& str, const Allocator& alloc);
basic_string(basic_string&& str, const Allocator& alloc);
```

1 *Effects:* Constructs an object of class `basic_string` as indicated in Table 69. The stored allocator is constructed from `alloc`. In the second form, `str` is left in a valid state with an unspecified value.

Table 69 — `basic_string(const basic_string&, const Allocator&)` and `basic_string(basic_string&&, const Allocator&)` effects

Element	Value
`data()`	points at the first element of an allocated copy of the array whose first element is pointed at by the original value of `str.data()`.
`size()`	the original value of `str.size()`
`capacity()`	a value at least as large as `size()`
`get_allocator()`	`alloc`

1 *Throws:* The second form throws nothing if `alloc == str.get_allocator()`.

```
basic_string& operator=(const basic_string& str);
```

1 *Effects:* If `*this` and `str` are not the same object, modifies `*this` as shown in Table 70.

1 If `*this` and `str` are the same object, the member has no effect.

2 *Returns:* `*this`

Table 70 — `operator=(const basic_string&)` effects

Element	Value
`data()`	points at the first element of an allocated copy of the array whose first element is pointed at by `str.data()`
`size()`	`str.size()`
`capacity()`	a value at least as large as `size()`

```
basic_string& operator=(basic_string&& str) noexcept;
```

3

Effects: If `*this` and `str` are not the same object, modifies `*this` as shown in Table 71. [*Note:* A valid implementation is `swap(str)`. — *end note*]

1 If `*this` and `str` are the same object, the member has no effect.

2 *Returns:* `*this`

Table 71 — `operator=(basic_string&&)` effects

Element	Value
`data()`	points at the array whose first element was pointed at by `str.data()`
`size()`	previous value of `str.size()`
`capacity()`	a value at least as large as `size()`

```
basic_string& operator=(const charT* s);
```

3 *Returns:* `*this = basic_string(s)`.

4 *Remarks:* Uses `traits::length()`.

```
basic_string& operator=(charT c);
```

5 *Returns:* `*this = basic_string(1,c)`.

```
basic_string& operator=(initializer_list<charT> il);
```

6 *Effects:* `*this = basic_string(il)`.

7 *Returns:* `*this`.

21.121.1 `basic_string` iterator support [string.iterators]

```
iterator       begin() noexcept;
const_iterator begin() const noexcept;
const_iterator cbegin() const noexcept;
```

1

Returns: An iterator referring to the first character in the string.

```
iterator       end() noexcept;
const_iterator end() const noexcept;
const_iterator cend() const noexcept;
```

1 *Returns:* An iterator which is the past-the-end value.

```
reverse_iterator       rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
const_reverse_iterator crbegin() const noexcept;
```

2 *Returns:* An iterator which is semantically equivalent to `reverse_iterator(end())`.

```
reverse_iterator       rend() noexcept;
const_reverse_iterator rend() const noexcept;
const_reverse_iterator crend() const noexcept;
```

3 *Returns:* An iterator which is semantically equivalent to `reverse_iterator(begin())`.

21.122.1 `basic_string` capacity [string.capacity]

```
size_type size() const noexcept;
```

1

Returns: A count of the number of char-like objects currently in the string.

1

Complexity: Constant time.

```
size_type length() const noexcept;
```

1

Returns: `size()`.

```
size_type max_size() const noexcept;
```

1 *Returns:* The size of the largest possible string.

2 *Complexity:* Constant time.

```
void resize(size_type n, charT c);
```

3 *Requires:* `n <= max_size()`

4 *Throws:* `length_error` if `n > max_size()`.

5

Effects: Alters the length of the string designated by `*this` as follows:

— If `n <= size()`, the function replaces the string designated by `*this` with a string of length `n` whose elements are a copy of the initial elements of the original string designated by `*this`.

— If `n > size()`, the function replaces the string designated by `*this` with a string of length `n` whose first `size()` elements are a copy of the original string designated by `*this`, and whose remaining elements are all initialized to `c`.

```
void resize(size_type n);
```

1 *Effects:* `resize(n,charT())`.

```
size_type capacity() const noexcept;
```

2 *Returns:* The size of the allocated storage in the string.

```
void reserve(size_type res_arg=0);
```

3

The member function `reserve()` is a directive that informs a `basic_string` object of a planned change in size, so that it can manage the storage allocation accordingly.

1

Effects: After `reserve()`, `capacity()` is greater or equal to the argument of `reserve`. [*Note:* Calling `reserve()` with a `res_arg` argument less than `capacity()` is in effect a non-binding shrink request. A call with `res_arg <= size()` is in effect a non-binding shrink-to-fit request. — *end note*]

1 *Throws:* `length_error` if `res_arg > max_size()`.[235]

```
void shrink_to_fit();
```

2 *Remarks:* `shrink_to_fit` is a non-binding request to reduce `capacity()` to `size()`. [*Note:* The request is non-binding to allow latitude for implementation-specific optimizations. — *end note*]

```
void clear() noexcept;
```

3 *Effects:* Behaves as if the function calls:

```
erase(begin(), end());
```

```
bool empty() const noexcept;
```

4 *Returns:* `size() == 0`.

21.141.1 `basic_string` element access [string.access]

```
const_reference operator[](size_type pos) const;
reference       operator[](size_type pos);
```

1 *Requires:* `pos <= size()`.

2

Returns: `*(begin() + pos)` if `pos < size()`. Otherwise, returns a reference to an object of type `charT` with value `charT()`, where modifying the object leads to undefined behavior.

1 *Throws:* Nothing.

2

Complexity: Constant time.

```
const_reference at(size_type pos) const;
reference       at(size_type pos);
```

1 *Throws:* `out_of_range` if `pos >= size()`.

2

Returns: `operator[](pos)`.

```
const charT& front() const;
charT& front();
```

1 *Requires:* `!empty()`

2 *Effects:* Equivalent to `operator[](0)`.

```
const charT& back() const;
charT& back();
```

3 *Requires:* `!empty()`

4 *Effects:* Equivalent to `operator[](size() - 1)`.

235) `reserve()` uses `allocator_traits<Allocator>::allocate()` which may throw an appropriate exception.

21.182.1 basic_string modifiers [string.modifiers]

21.182.1.1 basic_string::operator+= [string::op+=]

```
basic_string&
  operator+=(const basic_string& str);
```

1 *Effects:* Calls `append(str)`.

2 *Returns:* `*this`.

```
basic_string& operator+=(const charT* s);
```

3 *Effects:* Calls `append(s)`.

4 *Returns:* `*this`.

```
basic_string& operator+=(charT c);
```

5 *Effects:* Calls `push_back(c)`;

6 *Returns:* `*this`.

```
basic_string& operator+=(initializer_list<charT> il);
```

7 *Effects:* Calls `append(il)`.

8 *Returns:* `*this`.

21.182.1.2 basic_string::append [string::append]

```
basic_string&
  append(const basic_string& str);
```

1 *Effects:* Calls `append(str.data(), str.size())`.

2 *Returns:* `*this`.

```
basic_string&
  append(const basic_string& str, size_type pos, size_type n = npos);
```

1 *Requires:* `pos <= str.size()`

2 *Throws:* `out_of_range` if `pos > str.size()`.

3 *Effects:* Determines the effective length `rlen` of the string to append as the smaller of `n` and `str.size() - pos` and calls `append(str.data() + pos, rlen)`.

4 *Returns:* `*this`.

```
basic_string&
  append(const charT* s, size_type n);
```

1 *Requires:* `s` points to an array of at least `n` elements of `charT`.

2 *Throws:* `length_error` if `size() + n > max_size()`.

3 *Effects:* The function replaces the string controlled by `*this` with a string of length `size() + n` whose first `size()` elements are a copy of the original string controlled by `*this` and whose remaining elements are a copy of the initial `n` elements of `s`.

1 *Returns:* `*this`.

```
basic_string& append(const charT* s);
```

2 *Requires:* `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

3 *Effects:* Calls `append(s, traits::length(s))`.

4 *Returns:* `*this`.

```
basic_string& append(size_type n, charT c);
```

5 *Effects:* Equivalent to `append(basic_string(n, c))`.

6 *Returns:* `*this`.

```
template<class InputIterator>
  basic_string& append(InputIterator first, InputIterator last);
```

7 *Requires:* `[first,last)` is a valid range.

8 *Effects:* Equivalent to `append(basic_string(first, last))`.

9 *Returns:* `*this`.

```
basic_string& append(initializer_list<charT> il);
```

10 *Effects:* Calls `append(il.begin(), il.size())`.

11 *Returns:* `*this`.

```
void push_back(charT c);
```

12 *Effects:* Equivalent to `append(static_cast<size_type>(1), c)`.

21.186.0.1 `basic_string::assign` [string::assign]

```
basic_string& assign(const basic_string& str);
```

1 *Effects:* Equivalent to `assign(str, 0, npos)`.

2 *Returns:* `*this`.

```
basic_string& assign(basic_string&& str) noexcept;
```

3 *Effects:* The function replaces the string controlled by `*this` with a string of length `str.size()` whose elements are a copy of the string controlled by `str`. [*Note:* A valid implementation is `swap(str)`. — *end note*]

1 *Returns:* `*this`.

```
basic_string&
  assign(const basic_string& str, size_type pos,
         size_type n = npos);
```

2 *Requires:* `pos <= str.size()`

3 *Throws:* `out_of_range` if `pos > str.size()`.

4 *Effects:* Determines the effective length `rlen` of the string to assign as the smaller of `n` and `str.size() - pos` and calls `assign(str.data() + pos rlen)`.

1 *Returns:* `*this`.

```
basic_string& assign(const charT* s, size_type n);
```

2 *Requires:* `s` points to an array of at least `n` elements of `charT`.

3 *Throws:* `length_error` if `n > max_size()`.

4

Effects: Replaces the string controlled by `*this` with a string of length `n` whose elements are a copy of those pointed to by `s`.

1 *Returns:* `*this`.

```
basic_string& assign(const charT* s);
```

2 *Requires:* `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

3 *Effects:* Calls `assign(s, traits::length(s))`.

4 *Returns:* `*this`.

```
basic_string& assign(initializer_list<charT> il);
```

5 *Effects:* Calls `assign(il.begin(), il.size())`.

6 `*this`.

```
basic_string& assign(size_type n, charT c);
```

7 *Effects:* Equivalent to `assign(basic_string(n, c))`.

8 *Returns:* `*this`.

```
template<class InputIterator>
  basic_string& assign(InputIterator first, InputIterator last);
```

9 *Effects:* Equivalent to `assign(basic_string(first, last))`.

10 *Returns:* `*this`.

21.189.0.1 `basic_string::insert` [string::insert]

```
basic_string&
  insert(size_type pos1,
         const basic_string& str);
```

1 *Requires:* `pos <= size()`.

2 *Throws:* `out_of_range` if `pos > size()`.

3 *Effects:* Calls `insert(pos, str.data(), str.size())`.

4 *Returns:* `*this`.

```
basic_string&
  insert(size_type pos1,
         const basic_string& str,
         size_type pos2, size_type n = npos);
```

5

Requires: `pos1 <= size()` and `pos2 <= str.size()`

1 *Throws:* `out_of_range` if `pos1 > size()` or `pos2 > str.size()`.

2 *Effects:* Determines the effective length `rlen` of the string to insert as the smaller of `n` and `str.size() - pos2` and calls `insert(pos1, str.data() + pos2, rlen)`.

3 *Returns:* `*this`.

```
basic_string&
  insert(size_type pos, const charT* s, size_type n);
```

4 *Requires:* `s` points to an array of at least `n` elements of `charT` and `pos <= size()`.

5 *Throws:* `out_of_range` if `pos > size()` or `length_error` if `size() + n > max_size()`.

6 *Effects:* Replaces the string controlled by `*this` with a string of length `size() + n` whose first `pos` elements are a copy of the initial elements of the original string controlled by `*this` and whose next `n` elements are a copy of the elements in `s` and whose remaining elements are a copy of the remaining elements of the original string controlled by `*this`.

7 *Returns:* `*this`.

```
basic_string&
  insert(size_type pos, const charT* s);
```

8 *Requires:* `pos <= size()` and `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

9 *Effects:* Equivalent to `insert(pos, s, traits::length(s))`.

10 *Returns:* `*this`.

```
basic_string&
  insert(size_type pos, size_type n, charT c);
```

11 *Effects:* Equivalent to `insert(pos, basic_string(n, c))`.

12 *Returns:* `*this`.

```
iterator insert(const_iterator p, charT c);
```

13 *Requires:* `p` is a valid iterator on `*this`.

14 *Effects:* inserts a copy of `c` before the character referred to by `p`.

15 *Returns:* An iterator which refers to the copy of the inserted character.

```
iterator insert(const_iterator p, size_type n, charT c);
```

16 *Requires:* `p` is a valid iterator on `*this`.

17 *Effects:* inserts `n` copies of `c` before the character referred to by `p`.

18 *Returns:* An iterator which refers to the copy of the first inserted character, or `p` if `n == 0`.

```
template<class InputIterator>
  iterator insert(const_iterator p, InputIterator first, InputIterator last);
```

19 *Requires:* `p` is a valid iterator on `*this`. `[first,last)` is a valid range.

20 *Effects:* Equivalent to `insert(p - begin(), basic_string(first, last))`.

21 *Returns:* An iterator which refers to the copy of the first inserted character, or `p` if `first == last`.

```
iterator insert(const_iterator p, initializer_list<charT> il);
```

22 *Effects:* `insert(p, il.begin(), il.end())`.

23 *Returns:* An iterator which refers to the copy of the first inserted character, or `p` if `i1` is empty.

21.190.0.1 `basic_string::erase` [string::erase]

```
basic_string& erase(size_type pos = 0, size_type n = npos);
```

1 *Requires:* `pos <= size()`

2 *Throws:* `out_of_range` if `pos > size()`.

3

Effects: Determines the effective length `xlen` of the string to be removed as the smaller of `n` and `size() - pos`.

1

The function then replaces the string controlled by `*this` with a string of length `size() - xlen` whose first `pos` elements are a copy of the initial elements of the original string controlled by `*this`, and whose remaining elements are a copy of the elements of the original string controlled by `*this` beginning at position `pos + xlen`.

1 *Returns:* `*this`.

```
iterator erase(const_iterator p);
```

2 *Throws:* Nothing.

3 *Effects:* removes the character referred to by `p`.

4 *Returns:* An iterator which points to the element immediately following `p` prior to the element being erased. If no such element exists, `end()` is returned.

```
iterator erase(const_iterator first, const_iterator last);
```

5

Requires: `first` and `last` are valid iterators on `*this`, defining a range `[first,last)`.

1 *Throws:* Nothing.

2 *Effects:* removes the characters in the range `[first,last)`.

3 *Returns:* An iterator which points to the element pointed to by `last` prior to the other elements being erased. If no such element exists, `end()` is returned.

```
void pop_back();
```

4 *Requires:* `!empty()`

5 *Throws:* Nothing.

6 *Effects:* Equivalent to `erase(size() - 1, 1)`.

21.193.0.1 `basic_string::replace` [string::replace]

```
basic_string&
  replace(size_type pos1, size_type n1,
          const basic_string& str);
```

1 *Requires:* `pos1 <= size()`.

2 *Throws:* `out_of_range` if `pos1 > size()`.

3 *Effects:* Calls `replace(pos1, n1, str.data(), str.size())`.

4 *Returns:* `*this`.

```
basic_string&
  replace(size_type pos1, size_type n1,
          const basic_string& str,
          size_type pos2, size_type n2 = npos);
```

5 *Requires:* `pos1 <= size()` and `pos2 <= str.size()`.

6 *Throws:* `out_of_range` if `pos1 > size()` or `pos2 > str.size()`.

7 *Effects:* Determines the effective length `rlen` of the string to be inserted as the smaller of `n2` and `str.size() - pos2` and calls `replace(pos1, n1, str.data() + pos2, rlen)`.

8 *Returns:* `*this`.

```
basic_string&
  replace(size_type pos1, size_type n1, const charT* s, size_type n2);
```

9 *Requires:* `pos1 <= size()` and `s` points to an array of at least `n2` elements of `charT`.

10 *Throws:* `out_of_range` if `pos1 > size()` or `length_error` if the length of the resulting string would exceed `max_size()` (see below).

11

Effects: Determines the effective length `xlen` of the string to be removed as the smaller of `n1` and `size() - pos1`. If `size() - xlen >= max_size() - n2` throws `length_error`. Otherwise, the function replaces the string controlled by `*this` with a string of length `size() - xlen + n2` whose first `pos1` elements are a copy of the initial elements of the original string controlled by `*this`, whose next `n2` elements are a copy of the initial `n2` elements of `s`, and whose remaining elements are a copy of the elements of the original string controlled by `*this` beginning at position `pos + xlen`.

1 *Returns:* `*this`.

```
basic_string&
  replace(size_type pos, size_type n, const charT* s);
```

2 *Requires:* `pos <= size()` and `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

3 *Effects:* Calls `replace(pos, n, s, traits::length(s))`.

4 *Returns:* `*this`.

```
basic_string&
  replace(size_type pos1, size_type n1,
          size_type n2, charT c);
```

5 *Effects:* Equivalent to `replace(pos1, n1, basic_string(n2, c))`.

6 *Returns:* `*this`.

```
basic_string& replace(const_iterator i1, const_iterator i2, const basic_string& str);
```

7 *Requires:* `[begin(),i1)` and `[i1,i2)` are valid ranges.

8 *Effects:* Calls `replace(i1 - begin(), i2 - i1, str)`.

9 *Returns:* `*this`.

```
basic_string&
  replace(const_iterator i1, const_iterator i2, const charT* s, size_type n);
```

10 *Requires:* `[begin(),i1)` and `[i1,i2)` are valid ranges and `s` points to an array of at least `n` elements of `charT`.

11 *Effects:* Calls `replace(i1 - begin(), i2 - i1, s, n)`.

12 *Returns:* `*this`.

```
basic_string& replace(const_iterator i1, const_iterator i2, const charT* s);
```

13 *Requires:* `[begin(),i1)` and `[i1,i2)` are valid ranges and `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

14 *Effects:* Calls `replace(i1 - begin(), i2 - i1, s, traits::length(s))`.

15 *Returns:* `*this`.

```
basic_string& replace(const_iterator i1, const_iterator i2, size_type n,
                      charT c);
```

16 *Requires:* `[begin(),i1)` and `[i1,i2)` are valid ranges.

17 *Effects:* Calls `replace(i1 - begin(), i2 - i1, basic_string(n, c))`.

18 *Returns:* `*this`.

```
template<class InputIterator>
  basic_string& replace(const_iterator i1, const_iterator i2,
                        InputIterator j1, InputIterator j2);
```

19 *Requires:* `[begin(),i1)`, `[i1,i2)` and `[j1,j2)` are valid ranges.

20 *Effects:* Calls `replace(i1 - begin(), i2 - i1, basic_string(j1, j2))`.

21 *Returns:* `*this`.

```
basic_string& replace(const_iterator i1, const_iterator i2,
                      initializer_list<charT> il);
```

22 *Requires:* `[begin(),i1)` and `[i1,i2)` are valid ranges.

23 *Effects:* Calls `replace(i1 - begin(), i2 - i1, il.begin(), il.size())`.

24 *Returns:* `*this`.

21.196.0.1 `basic_string::copy` [**string::copy**]

```
size_type copy(charT* s, size_type n, size_type pos = 0) const;
```

1 *Requires:* `pos <= size()`

2 *Throws:* `out_of_range` if `pos > size()`.

3 *Effects:* Determines the effective length `rlen` of the string to copy as the smaller of `n` and `size() - pos`. `s` shall designate an array of at least `rlen` elements.

The function then replaces the string designated by `s` with a string of length `rlen` whose elements are a copy of the string controlled by `*this` beginning at position `pos`.

The function does not append a null object to the string designated by `s`.

4 *Returns:* `rlen`.

21.196.0.2 basic_string::swap [string::swap]

```
void swap(basic_string& s);
```

1

Postcondition: `*this` contains the same sequence of characters that was in `s`, `s` contains the same sequence of characters that was in `*this`.

1 *Throws:* Nothing.

2 *Complexity:* Constant time.

21.197.1 basic_string string operations [string.ops]

21.197.1.1 basic_string accessors [string.accessors]

```
const charT* c_str() const noexcept;
const charT* data() const noexcept;
```

1 *Returns:* A pointer `p` such that `p + i == &operator[](i)` for each `i` in `[0,size()]`.

2 *Complexity:* Constant time.

3

Requires: The program shall not alter any of the values stored in the character array.

```
allocator_type get_allocator() const noexcept;
```

1

Returns: A copy of the `Allocator` object used to construct the string or, if that allocator has been replaced, a copy of the most recent replacement.

21.203.0.1 basic_string::find [string::find]

```
size_type find(const basic_string& str,
               size_type pos = 0) const noexcept;
```

1

Effects: Determines the lowest position `xpos`, if possible, such that both of the following conditions obtain:

— `pos <= xpos` and `xpos + str.size() <= size()`;

— `traits::eq(at(xpos+I), str.at(I))` for all elements `I` of the string controlled by `str`.

1

Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

1 *Remarks:* Uses `traits::eq()`.

```
size_type find(const charT* s, size_type pos, size_type n) const;
```

2 *Returns:* `find(basic_string(s,n),pos)`.

```
size_type find(const charT* s, size_type pos = 0) const;
```

3 *Requires:* `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

4 *Returns:* `find(basic_string(s), pos)`.

```
size_type find(charT c, size_type pos = 0) const;
```

5 *Returns:* `find(basic_string(1,c), pos)`.

21.209.0.1 basic_string::rfind [string::rfind]

```
size_type rfind(const basic_string& str,
                size_type pos = npos) const noexcept;
```

1

Effects: Determines the highest position `xpos`, if possible, such that both of the following conditions obtain:

— `xpos <= pos` and `xpos + str.size() <= size()`;

— `traits::eq(at(xpos+I), str.at(I))` for all elements `I` of the string controlled by `str`.

1 *Returns:* `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

2 *Remarks:* Uses `traits::eq()`.

```
size_type rfind(const charT* s, size_type pos, size_type n) const;
```

3

Returns: `rfind(basic_string(s, n), pos)`.

```
size_type rfind(const charT* s, size_type pos = npos) const;
```

1 *Requires:* s points to an array of at least `traits::length(s) + 1` elements of `charT`.

2 *Returns:* `rfind(basic_string(s), pos)`.

```
size_type rfind(charT c, size_type pos = npos) const;
```

3 *Returns:* `rfind(basic_string(1,c),pos)`.

21.211.0.1 basic_string::find_first_of [string::find.first.of]

```
size_type
  find_first_of(const basic_string& str,
                size_type pos = 0) const noexcept;
```

1 *Effects:* Determines the lowest position `xpos`, if possible, such that both of the following conditions obtain:

(1.1) — `pos <= xpos` and `xpos < size()`;

(1.2) — `traits::eq(at(xpos), str.at(I))` for some element `I` of the string controlled by `str`.

2 *Returns:* `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

3 *Remarks:* Uses `traits::eq()`.

```
size_type
  find_first_of(const charT* s, size_type pos, size_type n) const;
```

4 *Returns:* `find_first_of(basic_string(s, n), pos)`.

```
size_type find_first_of(const charT* s, size_type pos = 0) const;
```

5 *Requires:* `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

6 *Returns:* `find_first_of(basic_string(s), pos)`.

```
size_type find_first_of(charT c, size_type pos = 0) const;
```

7 *Returns:* `find_first_of(basic_string(1,c), pos)`.

21.211.0.2 basic_string::find_last_of [string::find.last.of]

```
size_type
  find_last_of(const basic_string& str,
               size_type pos = npos) const noexcept;
```

1 *Effects:* Determines the highest position `xpos`, if possible, such that both of the following conditions obtain:

(1.1) — `xpos <= pos` and `xpos < size()`;

(1.2) — `traits::eq(at(xpos), str.at(I))` for some element `I` of the string controlled by `str`.

2 *Returns:* `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

3 *Remarks:* Uses `traits::eq()`.

```
size_type find_last_of(const charT* s, size_type pos, size_type n) const;
```

4 *Returns:* `find_last_of(basic_string(s, n), pos)`.

```
size_type find_last_of(const charT* s, size_type pos = npos) const;
```

5 *Requires:* `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

6 *Returns:* `find_last_of(basic_string(s), pos)`.

```
size_type find_last_of(charT c, size_type pos = npos) const;
```

7 *Returns:* `find_last_of(basic_string(1,c),pos)`.

21.211.0.3 basic_string::find_first_not_of [string::find.first.not.of]

```
size_type
  find_first_not_of(const basic_string& str,
                    size_type pos = 0) const noexcept;
```

1 *Effects:* Determines the lowest position `xpos`, if possible, such that both of the following conditions obtain:

(1.1) — `pos <= xpos` and `xpos < size()`;

(1.2) — `traits::eq(at(xpos), str.at(I))` for no element `I` of the string controlled by `str`.

2 *Returns:* `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

3 *Remarks:* Uses `traits::eq()`.

```
size_type
  find_first_not_of(const charT* s, size_type pos, size_type n) const;
```

4 *Returns:* `find_first_not_of(basic_string(s, n), pos)`.

```
size_type find_first_not_of(const charT* s, size_type pos = 0) const;
```

5 *Requires:* `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

6 *Returns:* `find_first_not_of(basic_string(s), pos)`.

```
size_type find_first_not_of(charT c, size_type pos = 0) const;
```

7 *Returns:* `find_first_not_of(basic_string(1, c), pos)`.

21.211.0.4 basic_string::find_last_not_of [string::find.last.not.of]

```
size_type
  find_last_not_of(const basic_string& str,
                   size_type pos = npos) const noexcept;
```

1 *Effects:* Determines the highest position `xpos`, if possible, such that both of the following conditions obtain:

(1.1) — `xpos <= pos` and `xpos < size()`;

(1.2) — `traits::eq(at(xpos), str.at(I))` for no element `I` of the string controlled by `str`.

2 *Returns:* `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

3 *Remarks:* Uses `traits::eq()`.

```
size_type find_last_not_of(const charT* s, size_type pos,
                           size_type n) const;
```

4 *Returns:* `find_last_not_of(basic_string(s, n), pos)`.

```
size_type find_last_not_of(const charT* s, size_type pos = npos) const;
```

5 *Requires:* `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

6 *Returns:* `find_last_not_of(basic_string(s), pos)`.

```
size_type find_last_not_of(charT c, size_type pos = npos) const;
```

7 *Returns:* `find_last_not_of(basic_string(1, c), pos)`.

21.211.0.5 basic_string::substr [string::substr]

```
basic_string substr(size_type pos = 0, size_type n = npos) const;
```

1 *Requires:* `pos <= size()`

2 *Throws:* `out_of_range` if `pos > size()`.

3 *Effects:* Determines the effective length `rlen` of the string to copy as the smaller of `n` and `size() - pos`.

4 *Returns:* `basic_string(data()+pos,rlen)`.

21.211.0.6 basic_string::compare [string::compare]

```
int compare(const basic_string& str) const noexcept;
```

1

Effects: Determines the effective length *rlen* of the strings to compare as the smallest of `size()` and `str.size()`. The function then compares the two strings by calling `traits::compare(data(), str.data(), rlen)`.

1

Returns: The nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as indicated in Table 72.

```
int compare(size_type pos1, size_type n1,
            const basic_string& str) const;
```

1

Returns: `basic_string(*this,pos1,n1).compare(str)`.

Table 72 — `compare()` results

Condition	Return Value
`size() < str.size()`	`< 0`
`size() == str.size()`	`0`
`size() > str.size()`	`> 0`

```
int compare(size_type pos1, size_type n1,
            const basic_string& str,
            size_type pos2, size_type n2 = npos) const;
```

1 *Returns:* `basic_string(*this, pos1, n1).compare(basic_string(str, pos2, n2))`.

```
int compare(const charT* s) const;
```

2 *Returns:* `compare(basic_string(s))`.

```
int compare(size_type pos, size_type n1,
            const charT* s) const;
```

3 *Returns:* `basic_string(*this, pos, n1).compare(basic_string(s))`.

```
int compare(size_type pos, size_type n1,
            const charT* s, size_type n2) const;
```

4 *Returns:* `basic_string(*this, pos, n1).compare(basic_string(s, n2))`.

21.217.1 basic_string non-member functions [string.nonmembers]

21.217.1.1 operator+ [string::op+]

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(const basic_string<charT,traits,Allocator>& lhs,
              const basic_string<charT,traits,Allocator>& rhs);
```

1 *Returns:* `basic_string<charT,traits,Allocator>(lhs).append(rhs)`

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(basic_string<charT,traits,Allocator>&& lhs,
              const basic_string<charT,traits,Allocator>& rhs);
```

2 *Returns:* `std::move(lhs.append(rhs))`

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(const basic_string<charT,traits,Allocator>& lhs,
              basic_string<charT,traits,Allocator>&& rhs);
```

3 *Returns:* `std::move(rhs.insert(0, lhs))`

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(basic_string<charT,traits,Allocator>&& lhs,
              basic_string<charT,traits,Allocator>&& rhs);
```

4 *Returns:* `std::move(lhs.append(rhs))` [*Note:* Or equivalently `std::move(rhs.insert(0, lhs))` — *end note*]

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(const charT* lhs,
              const basic_string<charT,traits,Allocator>& rhs);
```

5 *Returns:* `basic_string<charT,traits,Allocator>(lhs) + rhs`.

6 *Remarks:* Uses `traits::length()`.

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(const charT* lhs,
              basic_string<charT,traits,Allocator>&& rhs);
```

7 *Returns:* `std::move(rhs.insert(0, lhs))`.

8 *Remarks:* Uses `traits::length()`.

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(charT lhs,
              const basic_string<charT,traits,Allocator>& rhs);
```

9 *Returns:* `basic_string<charT,traits,Allocator>(1,lhs) + rhs`.

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(charT lhs,
              basic_string<charT,traits,Allocator>&& rhs);
```

10 *Returns:* `std::move(rhs.insert(0, 1, lhs))`.

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(const basic_string<charT,traits,Allocator>& lhs,
              const charT* rhs);
```

11 *Returns:* `lhs + basic_string<charT,traits,Allocator>(rhs)`.

12 *Remarks:* Uses `traits::length()`.

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(basic_string<charT,traits,Allocator>&& lhs,
              const charT* rhs);
```

13 *Returns:* `std::move(lhs.append(rhs))`.

14 *Remarks:* Uses `traits::length()`.

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(const basic_string<charT,traits,Allocator>& lhs,
              charT rhs);
```

15 *Returns:* `lhs + basic_string<charT,traits,Allocator>(1,rhs)`.

```
template<class charT, class traits, class Allocator>
  basic_string<charT,traits,Allocator>
    operator+(basic_string<charT,traits,Allocator>&& lhs,
              charT rhs);
```

16 *Returns:* `std::move(lhs.append(1, rhs))`.

21.217.1.2 `operator==` [string::operator==]

```
template<class charT, class traits, class Allocator>
  bool operator==(const basic_string<charT,traits,Allocator>& lhs,
                  const basic_string<charT,traits,Allocator>& rhs) noexcept;
```

1 *Returns:* `lhs.compare(rhs) == 0`.

```
template<class charT, class traits, class Allocator>
  bool operator==(const charT* lhs,
                  const basic_string<charT,traits,Allocator>& rhs);
```

2 *Returns:* `rhs == lhs`.

```
template<class charT, class traits, class Allocator>
  bool operator==(const basic_string<charT,traits,Allocator>& lhs,
                  const charT* rhs);
```

3 *Requires:* `rhs` points to an array of at least `traits::length(rhs) + 1` elements of `charT`.

4 *Returns:* `lhs.compare(rhs) == 0`.

21.217.1.3 `operator!=` [string::op!=]

```
template<class charT, class traits, class Allocator>
  bool operator!=(const basic_string<charT,traits,Allocator>& lhs,
                  const basic_string<charT,traits,Allocator>& rhs) noexcept;
```

1 *Returns:* `!(lhs == rhs)`.

```
template<class charT, class traits, class Allocator>
  bool operator!=(const charT* lhs,
                  const basic_string<charT,traits,Allocator>& rhs);
```

2 *Returns:* `rhs != lhs`.

```
template<class charT, class traits, class Allocator>
  bool operator!=(const basic_string<charT,traits,Allocator>& lhs,
                  const charT* rhs);
```

3 *Requires:* `rhs` points to an array of at least `traits::length(rhs) + 1` elements of `charT`.

4 *Returns:* `lhs.compare(rhs) != 0`.

21.217.1.4 `operator<` [string::op<]

```
template<class charT, class traits, class Allocator>
  bool operator< (const basic_string<charT,traits,Allocator>& lhs,
                  const basic_string<charT,traits,Allocator>& rhs) noexcept;
```

1 *Returns:* `lhs.compare(rhs) < 0`.

```
template<class charT, class traits, class Allocator>
  bool operator< (const charT* lhs,
                  const basic_string<charT,traits,Allocator>& rhs);
```

2 *Returns:* `rhs.compare(lhs) > 0`.

```
template<class charT, class traits, class Allocator>
  bool operator< (const basic_string<charT,traits,Allocator>& lhs,
                  const charT* rhs);
```

3 *Returns:* `lhs.compare(rhs) < 0`.

21.217.1.5 operator> [string::op>]

```
template<class charT, class traits, class Allocator>
  bool operator> (const basic_string<charT,traits,Allocator>& lhs,
                  const basic_string<charT,traits,Allocator>& rhs) noexcept;
```

1 *Returns:* `lhs.compare(rhs) > 0`.

```
template<class charT, class traits, class Allocator>
  bool operator> (const charT* lhs,
                  const basic_string<charT,traits,Allocator>& rhs);
```

2 *Returns:* `rhs.compare(lhs) < 0`.

```
template<class charT, class traits, class Allocator>
  bool operator> (const basic_string<charT,traits,Allocator>& lhs,
                  const charT* rhs);
```

3 *Returns:* `lhs.compare(rhs) > 0`.

21.217.1.6 operator<= [string::op<=]

```
template<class charT, class traits, class Allocator>
  bool operator<=(const basic_string<charT,traits,Allocator>& lhs,
                  const basic_string<charT,traits,Allocator>& rhs) noexcept;
```

1 *Returns:* `lhs.compare(rhs) <= 0`.

```
template<class charT, class traits, class Allocator>
  bool operator<=(const charT* lhs,
                  const basic_string<charT,traits,Allocator>& rhs);
```

2 *Returns:* `rhs.compare(lhs) >= 0`.

```
template<class charT, class traits, class Allocator>
  bool operator<=(const basic_string<charT,traits,Allocator>& lhs,
                  const charT* rhs);
```

3 *Returns:* `lhs.compare(rhs) <= 0`.

21.217.1.7 operator>= [string::op>=]

```
template<class charT, class traits, class Allocator>
  bool operator>=(const basic_string<charT,traits,Allocator>& lhs,
                  const basic_string<charT,traits,Allocator>& rhs) noexcept;
```

1 *Returns:* `lhs.compare(rhs) >= 0`.

```
template<class charT, class traits, class Allocator>
  bool operator>=(const charT* lhs,
                  const basic_string<charT,traits,Allocator>& rhs);
```

2 *Returns:* `rhs.compare(lhs) <= 0`.

```
template<class charT, class traits, class Allocator>
  bool operator>=(const basic_string<charT,traits,Allocator>& lhs,
                  const charT* rhs);
```

3 *Returns:* `lhs.compare(rhs) >= 0`.

21.217.1.8 swap [string.special]

```
template<class charT, class traits, class Allocator>
  void swap(basic_string<charT,traits,Allocator>& lhs,
    basic_string<charT,traits,Allocator>& rhs);
```

1 *Effects:* Equivalent to `lhs.swap(rhs);`

21.217.1.9 Inserters and extractors [string.io]

```
template<class charT, class traits, class Allocator>
  basic_istream<charT,traits>&
    operator>>(basic_istream<charT,traits>& is,
               basic_string<charT,traits,Allocator>& str);
```

1

Effects: Behaves as a formatted input function (27.128.0.1.1). After constructing a `sentry` object, if the sentry converts to true, calls `str.erase()` and then extracts characters from `is` and appends them to `str` as if by calling `str.append(1,c)`. If `is.width()` is greater than zero, the maximum number `n` of characters appended is `is.width()`; otherwise `n` is `str.max_size()`. Characters are extracted and appended until any of the following occurs:

— n characters are stored;

— end-of-file occurs on the input sequence;

— `isspace(c,is.getloc())` is true for the next available input character c.

1

After the last character (if any) is extracted, `is.width(0)` is called and the `sentry` object `k` is destroyed.

1

If the function extracts no characters, it calls `is.setstate(ios::failbit)`, which may throw `ios_base::failure` (27.84.0.1).

1 *Returns:* `is`

```
template<class charT, class traits, class Allocator>
  basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os,
               const basic_string<charT,traits,Allocator>& str);
```

2 *Effects:* Behaves as a formatted output function (27.198.0.1.1) of `os`. Forms a character sequence `seq`, initially consisting of the elements defined by the range [`str.begin(), str.end()`). Determines padding for `seq` as described in 27.198.0.1.1. Then inserts `seq` as if by calling `os.rdbuf()->sputn(seq, n)`, where `n` is the larger of `os.width()` and `str.size()`; then calls `os.width(0)`.

3 *Returns:* `os`

```
template<class charT, class traits, class Allocator>
  basic_istream<charT,traits>&
    getline(basic_istream<charT,traits>& is,
            basic_string<charT,traits,Allocator>& str,
            charT delim);
template<class charT, class traits, class Allocator>
  basic_istream<charT,traits>&
    getline(basic_istream<charT,traits>&& is,
            basic_string<charT,traits,Allocator>& str,
            charT delim);
```

4

Effects: Behaves as an unformatted input function (27.154.0.1), except that it does not affect the value returned by subsequent calls to `basic_istream<>::gcount()`. After constructing a `sentry` object, if the sentry converts to true, calls `str.erase()` and then extracts characters from `is` and appends them to `str` as if by calling `str.append(1, c)` until any of the following occurs:

— end-of-file occurs on the input sequence (in which case, the `getline` function calls `is.setstate(ios_base::eofbit)`).

— `traits::eq(c, delim)` for the next available input character *c* (in which case, *c* is extracted but not appended) (27.84.0.1)

— `str.max_size()` characters are stored (in which case, the function calls `is.setstate(ios_base::failbit))` (27.84.0.1)

1

The conditions are tested in the order shown. In any case, after the last character is extracted, the `sentry` object `k` is destroyed.

1 If the function extracts no characters, it calls `is.setstate(ios_base::failbit)` which may throw `ios_base::failure` (27.84.0.1).

2 *Returns:* `is`.

```
template<class charT, class traits, class Allocator>
  basic_istream<charT,traits>&
    getline(basic_istream<charT,traits>& is,
            basic_string<charT,traits,Allocator>& str);
template<class charT, class traits, class Allocator>
  basic_istream<charT,traits>&
    getline(basic_istream<charT,traits>&& is,
            basic_string<charT,traits,Allocator>& str);
```

3 *Returns:* `getline(is,str,is.widen('\n'))`

21.242 Numeric conversions [string.conversions]

```
int stoi(const string& str, size_t* idx = 0, int base = 10);
long stol(const string& str, size_t* idx = 0, int base = 10);
unsigned long stoul(const string& str, size_t* idx = 0, int base = 10);
long long stoll(const string& str, size_t* idx = 0, int base = 10);
unsigned long long stoull(const string& str, size_t* idx = 0, int base = 10);
```

1

Effects: the first two functions call `strtol(str.c_str(), ptr, base)`, and the last three functions call `strtoul(str.c_str(), ptr, base)`, `strtoll(str.c_str(), ptr, base)`, and `strtoull(str.c_str(), ptr, base)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != 0`, the function stores in `*idx` the index of the first unconverted element of `str`.

1 *Returns:* The converted result.

2

Throws: `invalid_argument` if `strtol`, `strtoul`, `strtoll`, or `strtoull` reports that no conversion could be performed. Throws `out_of_range` if `strtol`, `strtoul`, `strtoll` or `strtoull` sets `errno` to `ERANGE`, or if the converted value is outside the range of representable values for the return type.

```
float stof(const string& str, size_t* idx = 0);
double stod(const string& str, size_t* idx = 0);
long double stold(const string& str, size_t* idx = 0);
```

1

Effects: the first two functions call `strtod(str.c_str(), ptr)` and the third function calls `strtold(str.c_str(), ptr)`. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != 0`, the function stores in `*idx` the index of the first unconverted element of `str`.

1 *Returns:* The converted result.

2

Throws: `invalid_argument` if `strtod` or `strtold` reports that no conversion could be performed. Throws `out_of_range` if `strtod` or `strtold` sets `errno` to `ERANGE` or if the converted value is outside the range of representable values for the return type.

```
string to_string(int val);
string to_string(unsigned val);
string to_string(long val);
string to_string(unsigned long val);
string to_string(long long val);
string to_string(unsigned long long val);
string to_string(float val);
string to_string(double val);
string to_string(long double val);
```

1

Returns: Each function returns a `string` object holding the character representation of the value of its argument that would be generated by calling `sprintf(buf, fmt, val)` with a format specifier of `"%d"`, `"%u"`, `"%ld"`, `"%lu"`, `"%lld"`, `"%llu"`, `"%f"`, `"%f"`, or `"%Lf"`, respectively, where `buf` designates an internal character buffer of sufficient size.

```
int stoi(const wstring& str, size_t* idx = 0, int base = 10);
long stol(const wstring& str, size_t* idx = 0, int base = 10);
unsigned long stoul(const wstring& str, size_t* idx = 0, int base = 10);
long long stoll(const wstring& str, size_t* idx = 0, int base = 10);
unsigned long long stoull(const wstring& str, size_t* idx = 0, int base = 10);
```

1 *Effects:* the first two functions call `wcstol(str.c_str(), ptr, base)`, and the last three functions call `wcstoul(str.c_str(), ptr, base)`, `wcstoll(str.c_str(), ptr, base)`, and `wcstoull(str.c_str(), ptr, base)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != 0`, the function stores in `*idx` the index of the first unconverted element of `str`.

2 *Returns:* The converted result.

3 *Throws:* `invalid_argument` if `wcstol`, `wcstoul`, `wcstoll`, or `wcstoull` reports that no conversion could be performed. Throws `out_of_range` if the converted value is outside the range of representable values for the return type.

```
float stof(const wstring& str, size_t* idx = 0);
double stod(const wstring& str, size_t* idx = 0);
long double stold(const wstring& str, size_t* idx = 0);
```

4 *Effects:* the first two functions call `wcstod(str.c_str(), ptr)` and the third function calls `wcstold(str.c_str(), ptr)`. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != 0`, the function stores in `*idx` the index of the first unconverted element of `str`.

5 *Returns:* The converted result.

6 *Throws:* `invalid_argument` if `wcstod` or `wcstold` reports that no conversion could be performed. Throws `out_of_range` if `wcstod` or `wcstold` sets `errno` to `ERANGE`.

```
wstring to_wstring(int val);
wstring to_wstring(unsigned val);
wstring to_wstring(long val);
wstring to_wstring(unsigned long val);
wstring to_wstring(long long val);
wstring to_wstring(unsigned long long val);
wstring to_wstring(float val);
wstring to_wstring(double val);
wstring to_wstring(long double val);
```

7 *Returns:* Each function returns a `wstring` object holding the character representation of the value of its argument that would be generated by calling `swprintf(buf, buffsz, fmt, val)` with a format specifier of `L"%d"`, `L"%u"`, `L"%ld"`, `L"%lu"`, `L"%lld"`, `L"%llu"`, `L"%f"`, `L"%f"`, or `L"%Lf"`, respectively, where `buf` designates an internal character buffer of sufficient size `buffsz`.

21.258 Hash support [basic.string.hash]

```
template <> struct hash<string>;
template <> struct hash<u16string>;
template <> struct hash<u32string>;
template <> struct hash<wstring>;
```

1 The template specializations shall meet the requirements of class template `hash` (20.443.1).

21.259 Suffix for `basic_string` literals [basic.string.literals]

```
string operator "" s(const char* str, size_t len);
```

1 *Returns:* `string{str,len}`

```
u16string operator "" s(const char16_t* str, size_t len);
```

1 *Returns:* `u16string{str,len}`

```
u32string operator "" s(const char32_t* str, size_t len);
```

2 *Returns:* `u32string{str,len}`

```
wstring operator "" s(const wchar_t* str, size_t len);
```

3 *Returns:* `wstring{str,len}`

4 [*Note:* The same suffix `s` is used for `chrono::duration` literals denoting seconds but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. — *end note*]

21.261 Null-terminated sequence utilities [c.strings]

1

Tables 74, 75, 76, 77, 78, and 79 describe headers `<cctype>`, `<cwctype>`, `<cstring>`, `<cwchar>`, `<cstdlib>` (character conversions), and `<cuchar>`, respectively.

1

The contents of these headers shall be the same as the Standard C Library headers `<ctype.h>`, `<wctype.h>`, `<string.h>`, `<wchar.h>`, and `<stdlib.h>` and the C Unicode TR header `<uchar.h>`, respectively, with the following modifications:

1

The headers shall not define the types `char16_t`, `char32_t`, and `wchar_t` (2.287).

1 The function signature `strchr(const char*, int)` shall be replaced by the two declarations:

```
const char* strchr(const char* s, int c);
      char* strchr(      char* s, int c);
```

both of which shall have the same behavior as the original declaration.

2

The function signature `strpbrk(const char*, const char*)` shall be replaced by the two declarations:

```
const char* strpbrk(const char* s1, const char* s2);
      char* strpbrk(      char* s1, const char* s2);
```

both of which shall have the same behavior as the original declaration.

1 The function signature `strrchr(const char*, int)` shall be replaced by the two declarations:

```
const char* strrchr(const char* s, int c);
      char* strrchr(      char* s, int c);
```

both of which shall have the same behavior as the original declaration.

2 The function signature `strstr(const char*, const char*)` shall be replaced by the two declarations:

```
const char* strstr(const char* s1, const char* s2);
      char* strstr(      char* s1, const char* s2);
```

both of which shall have the same behavior as the original declaration.

3

The function signature `memchr(const void*, int, size_t)` shall be replaced by the two declarations:

```
const void* memchr(const void* s, int c, size_t n);
      void* memchr(      void* s, int c, size_t n);
```

both of which shall have the same behavior as the original declaration.

1 The function signature `wcschr(const wchar_t*, wchar_t)` shall be replaced by the two declarations:

```
const wchar_t* wcschr(const wchar_t* s, wchar_t c);
      wchar_t* wcschr(      wchar_t* s, wchar_t c);
```

both of which shall have the same behavior as the original declaration.

2 The function signature `wcspbrk(const wchar_t*, const wchar_t*)` shall be replaced by the two declarations:

```
const wchar_t* wcspbrk(const wchar_t* s1, const wchar_t* s2);
      wchar_t* wcspbrk(      wchar_t* s1, const wchar_t* s2);
```

both of which shall have the same behavior as the original declaration.

3 The function signature `wcsrchr(const wchar_t*, wchar_t)` shall be replaced by the two declarations:

```
const wchar_t* wcsrchr(const wchar_t* s, wchar_t c);
      wchar_t* wcsrchr(      wchar_t* s, wchar_t c);
```

both of which shall have the same behavior as the original declaration.

4 The function signature `wcsstr(const wchar_t*, const wchar_t*)` shall be replaced by the two declarations:

```
const wchar_t* wcsstr(const wchar_t* s1, const wchar_t* s2);
      wchar_t* wcsstr(      wchar_t* s1, const wchar_t* s2);
```

both of which shall have the same behavior as the original declaration.

5 The function signature `wmemchr(const wwchar_t*, int, size_t)` shall be replaced by the two declarations:

```
const wchar_t* wmemchr(const wchar_t* s, wchar_t c, size_t n);
      wchar_t* wmemchr(      wchar_t* s, wchar_t c, size_t n);
```

both of which shall have the same behavior as the original declaration.

6 The functions `strerror` and `strtok` are not required to avoid data races (17.607.0.1).

7

Calling the functions listed in Table 73 with an `mbstate_t*` argument of `NULL` may introduce a data race (17.607.0.1) with other calls to these functions with an `mbstate_t*` argument of `NULL`.

22 Localization library [localization]

22.1 General [localization.general]

1 This Clause describes components that C++ programs may use to encapsulate (and therefore be more portable when confronting) cultural differences. The locale facility includes internationalization support for character classification and string collation, numeric, monetary, and date/time formatting and parsing, and message retrieval.

2 The following subclauses describe components for locales themselves, the standard facets, and facilities from the ISO C library, as summarized in Table 80.

Table 80 — Localization library summary

Subclause		Header(s)
22.3	Locales	`<locale>`
22.31	Standard `locale` Categories	
22.108	Standard code conversion facets	`<codecvt>`
22.118	C library locales	`<clocale>`

22.2 Header `<locale>` synopsis [locale.syn]

```
namespace std {
  // 22.3.1, locale:
  class locale;
  template <class Facet> const Facet& use_facet(const locale&);
  template <class Facet> bool         has_facet(const locale&) noexcept;

  // 22.25.2, convenience interfaces:
  template <class charT> bool isspace (charT c, const locale& loc);
  template <class charT> bool isprint (charT c, const locale& loc);
  template <class charT> bool iscntrl (charT c, const locale& loc);
  template <class charT> bool isupper (charT c, const locale& loc);
  template <class charT> bool islower (charT c, const locale& loc);
  template <class charT> bool isalpha (charT c, const locale& loc);
  template <class charT> bool isdigit (charT c, const locale& loc);
  template <class charT> bool ispunct (charT c, const locale& loc);
  template <class charT> bool isxdigit(charT c, const locale& loc);
  template <class charT> bool isalnum (charT c, const locale& loc);
  template <class charT> bool isgraph (charT c, const locale& loc);
  template <class charT> bool isblank (charT c, const locale& loc);
  template <class charT> charT toupper(charT c, const locale& loc);
  template <class charT> charT tolower(charT c, const locale& loc);
  template <class Codecvt, class Elem = wchar_t,
    class Wide_alloc = std::allocator<Elem>,
    class Byte_alloc = std::allocator<char> > class wstring_convert;
  template <class Codecvt, class Elem = wchar_t,
     class Tr = char_traits<Elem>> class wbuffer_convert;

  // 22.31.1, ctype:
  class ctype_base;
```

```
  template <class charT> class ctype;
  template <>            class ctype<char>;              // specialization
  template <class charT> class ctype_byname;
  class codecvt_base;
  template <class internT, class externT, class stateT> class codecvt;
  template <class internT, class externT, class stateT> class codecvt_byname;

  // 22.44.1, numeric:
  template <class charT, class InputIterator = istreambuf_iterator<charT> >  class num_get;
  template <class charT, class OutputIterator = ostreambuf_iterator<charT> > class num_put;
  template <class charT> class numpunct;
  template <class charT> class numpunct_byname;

  // 22.102.2, collation:
  template <class charT> class collate;
  template <class charT> class collate_byname;

  // 22.102.3, date and time:
  class time_base;
  template <class charT, class InputIterator = istreambuf_iterator<charT> >
    class time_get;
  template <class charT, class InputIterator = istreambuf_iterator<charT> >
    class time_get_byname;
  template <class charT, class OutputIterator = ostreambuf_iterator<charT> >
    class time_put;
  template <class charT, class OutputIterator = ostreambuf_iterator<charT> >
    class time_put_byname;

  // 22.105.1, money:
  class money_base;
  template <class charT, class InputIterator = istreambuf_iterator<charT> >  class money_get;
  template <class charT, class OutputIterator = ostreambuf_iterator<charT> > class money_put;
  template <class charT, bool Intl = false> class moneypunct;
  template <class charT, bool Intl = false> class moneypunct_byname;

  // 22.107.1, message retrieval:
  class messages_base;
  template <class charT> class messages;
  template <class charT> class messages_byname;
}
```

1 The header `<locale>` defines classes and declares functions that encapsulate and manipulate the information peculiar to a locale.[236]

22.3 Locales [locales]

22.3.1 Class `locale` [locale]

```
namespace std {
  class locale {
  public:
    // types:
    class facet;
    class id;
    typedef int category;
```

236) In this subclause, the type name `struct tm` is an incomplete type that is defined in `<ctime>`.

```
    static const category   // values assigned here are for exposition only
      none     = 0,
      collate  = 0x010, ctype    = 0x020,
      monetary = 0x040, numeric  = 0x080,
      time     = 0x100, messages = 0x200,
      all = collate | ctype | monetary | numeric | time  | messages;

    // construct/copy/destroy:
    locale() noexcept;
    locale(const locale& other) noexcept;
    explicit locale(const char* std_name);
    explicit locale(const string& std_name);
    locale(const locale& other, const char* std_name, category);
    locale(const locale& other, const string& std_name, category);
    template <class Facet> locale(const locale& other, Facet* f);
    locale(const locale& other, const locale& one, category);
    ~locale();                  // not virtual
    const locale& operator=(const locale& other) noexcept;
    template <class Facet> locale combine(const locale& other) const;

    // locale operations:
    basic_string<char>                 name() const;

    bool operator==(const locale& other) const;
    bool operator!=(const locale& other) const;

    template <class charT, class traits, class Allocator>
      bool operator()(const basic_string<charT,traits,Allocator>& s1,
                      const basic_string<charT,traits,Allocator>& s2) const;

    // global locale objects:
    static       locale  global(const locale&);
    static const locale& classic();
  };
}
```

1 Class `locale` implements a type-safe polymorphic set of facets, indexed by facet *type*. In other words, a facet has a dual role: in one sense, it's just a class interface; at the same time, it's an index into a locale's set of facets.

2 Access to the facets of a `locale` is via two function templates, `use_facet<>` and `has_facet<>`.

3

[*Example:* An iostream `operator<<` might be implemented as:[237]

```
template <class charT, class traits>
basic_ostream<charT,traits>&
operator<< (basic_ostream<charT,traits>& s, Date d) {
  typename basic_ostream<charT,traits>::sentry cerberos(s);
  if (cerberos) {
    ios_base::iostate err = ios_base::iostate::goodbit;
    tm tmbuf; d.extract(tmbuf);
    use_facet< time_put<charT,ostreambuf_iterator<charT,traits> > >(
      s.getloc()).put(s, s, s.fill(), err, &tmbuf, 'x');
```

237) Note that in the call to `put` the stream is implicitly converted to an `ostreambuf_iterator<charT,traits>`.

```
    s.setstate(err);            // might throw
  }
  return s;
}
```

— *end example*]

1 In the call to `use_facet<Facet>(loc)`, the type argument chooses a facet, making available all members of the named type. If `Facet` is not present in a locale, it throws the standard exception `bad_cast`. A C++ program can check if a locale implements a particular facet with the function template `has_facet<Facet>()`. User-defined facets may be installed in a locale, and used identically as may standard facets (22.107.2).

2

[*Note:* All locale semantics are accessed via `use_facet<>` and `has_facet<>`, except that:

— A member operator template `operator()(const basic_string<C, T, A>&, const basic_string<C, T, A>&)` is provided so that a locale may be used as a predicate argument to the standard collections, to collate strings.

— Convenient global interfaces are provided for traditional `ctype` functions such as `isdigit()` and `isspace()`, so that given a locale object `loc` a C++ program can call `isspace(c,loc)`. (This eases upgrading existing extractors (27.128.0.1).) — *end note*]

1

Once a facet reference is obtained from a locale object by calling `use_facet<>`, that reference remains usable, and the results from member functions of it may be cached and re-used, as long as some locale object refers to that facet.

1 In successive calls to a locale facet member function on a facet object installed in the same locale, the returned result shall be identical.

2 A `locale` constructed from a name string (such as `"POSIX"`), or from parts of two named locales, has a name; all others do not. Named locales may be compared for equality; an unnamed locale is equal only to (copies of) itself. For an unnamed locale, `locale::name()` returns the string `"*"`.

3 Whether there is one global locale object for the entire program or one global locale object per thread is implementation-defined. Implementations should provide one global locale object per thread. If there is a single global locale object for the entire program, implementations are not required to avoid data races on it (17.607.0.1).

22.6.0.1 `locale` types [locale.types]

22.6.0.1.1 Type `locale::category` [locale.category]

```
typedef int category;
```

1 *Valid* `category` values include the `locale` member bitmask elements `collate`, `ctype`, `monetary`, `numeric`, `time`, and `messages`, each of which represents a single locale category. In addition, `locale` member bitmask constant `none` is defined as zero and represents no category. And `locale` member bitmask constant `all` is defined such that the expression

```
(collate | ctype | monetary | numeric | time | messages | all) == all
```

is `true`, and represents the union of all categories. Further, the expression `(X | Y)`, where `X` and `Y` each represent a single category, represents the union of the two categories.

Table 81 — Locale category facets

Category	Includes facets
collate	`collate<char>`, `collate<wchar_t>`

ctype	`ctype<char>`, `ctype<wchar_t>`
	`codecvt<char,char,mbstate_t>`
	`codecvt<char16_t,char,mbstate_t>`
	`codecvt<char32_t,char,mbstate_t>`
	`codecvt<wchar_t,char,mbstate_t>`

monetary	`moneypunct<char>`, `moneypunct<wchar_t>`
	`moneypunct<char,true>`, `moneypunct<wchar_t,true>`
	`money_get<char>`, `money_get<wchar_t>`
	`money_put<char>`, `money_put<wchar_t>`

numeric	`numpunct<char>`, `numpunct<wchar_t>`
	`num_get<char>`, `num_get<wchar_t>`
	`num_put<char>`, `num_put<wchar_t>`

time	`time_get<char>`, `time_get<wchar_t>` `time_put<char>`, `time_put<wchar_t>`
messages	`messages<char>`, `messages<wchar_t>`

2 `locale` member functions expecting a `category` argument require one of the `category` values defined above, or the union of two or more such values. Such a `category` value identifies a set of locale categories. Each locale category, in turn, identifies a set of locale facets, including at least those shown in Table 81.

3 For any locale `loc` either constructed, or returned by `locale::classic()`, and any facet `Facet` shown in Table 81, `has_facet<Facet>(loc)` is true. Each `locale` member function which takes a `locale::category` argument operates on the corresponding set of facets.

4 An implementation is required to provide those specializations for facet templates identified as members of a category, and for those shown in Table 82.

5 The provided implementation of members of facets `num_get<charT>` and `num_put<charT>` calls `use_facet<F>(l)` only for facet `F` of types `numpunct<charT>` and `ctype<charT>`, and for locale `l` the value obtained by calling member `getloc()` on the `ios_base&` argument to these functions.

6 In declarations of facets, a template parameter with name `InputIterator` or `OutputIterator` indicates the set of all possible specializations on parameters that satisfy the requirements of an Input Iterator or an Output Iterator, respectively (24.2). A template parameter with name `C` represents the set of types containing `char`, `wchar_t`, and any other implementation-defined character types that satisfy the requirements for a character on which any of the iostream components can be instantiated. A template parameter with name `International` represents the set of all possible specializations on a bool parameter.

22.6.0.1.2 Class `locale::facet` [locale.facet]

```
namespace std {
  class locale::facet {
  protected:
    explicit facet(size_t refs = 0);
    virtual ~facet();
    facet(const facet&) = delete;
    void operator=(const facet&) = delete;
  };
}
```

1 Template parameters in this Clause which are required to be facets are those named `Facet` in declarations. A

Table 82 — Required specializations

Category	Includes facets
collate	`collate_byname<char>`, `collate_byname<wchar_t>`

ctype	`ctype_byname<char>`, `ctype_byname<wchar_t>`
	`codecvt_byname<char,char,mbstate_t>`
	`codecvt_byname<char16_t,char,mbstate_t>`
	`codecvt_byname<char32_t,char,mbstate_t>`
	`codecvt_byname<wchar_t,char,mbstate_t>`

monetary	`moneypunct_byname<char,International>`
	`moneypunct_byname<wchar_t,International>`
	`money_get<C,InputIterator>`
	`money_put<C,OutputIterator>`

numeric	`numpunct_byname<char>`, `numpunct_byname<wchar_t>` `num_get<C,InputIterator>`, `num_put<C,OutputIterator>`

time	`time_get<char,InputIterator>`
	`time_get_byname<char,InputIterator>`
	`time_get<wchar_t,InputIterator>`
	`time_get_byname<wchar_t,InputIterator>`
	`time_put<char,OutputIterator>`
	`time_put_byname<char,OutputIterator>`
	`time_put<wchar_t,OutputIterator>`
	`time_put_byname<wchar_t,OutputIterator>`

messages	`messages_byname<char>`, `messages_byname<wchar_t>`

program that passes a type that is *not* a facet, or a type that refers to a volatile-qualified facet, as an (explicit or deduced) template parameter to a locale function expecting a facet, is ill-formed. A const-qualified facet is a valid template argument to any locale function that expects a Facet template parameter.

2

The `refs` argument to the constructor is used for lifetime management.

— For `refs == 0`, the implementation performs `delete static_cast<locale::facet*>(f)` (where `f` is a pointer to the facet) when the last `locale` object containing the facet is destroyed; for `refs == 1`, the implementation never destroys the facet.

1 Constructors of all facets defined in this Clause take such an argument and pass it along to their `facet` base class constructor. All one-argument constructors defined in this Clause are *explicit*, preventing their participation in automatic conversions.

2

For some standard facets a standard "…`_byname`" class, derived from it, implements the virtual function semantics equivalent to that facet of the locale constructed by `locale(const char*)` with the same name. Each such facet provides a constructor that takes a `const char*` argument, which names the locale, and a `refs` argument, which is passed to the base class constructor. Each such facet also provides a constructor that takes a `string` argument `str` and a `refs` argument, which has the same effect as calling the first constructor with the two arguments `str.c_str()` and `refs`. If there is no "…`_byname`" version of a facet, the base class implements named locale semantics itself by reference to other facets.

22.14.0.0.1 Class `locale::id` [locale.id]

```
namespace std {
  class locale::id {
```

```
  public:
    id();
    void operator=(const id&) = delete;
    id(const id&) = delete;
  };
}
```

1 The class locale::id provides identification of a locale facet interface, used as an index for lookup and to encapsulate initialization.

2 [*Note:* Because facets are used by iostreams, potentially while static constructors are running, their initialization cannot depend on programmed static initialization. One initialization strategy is for `locale` to initialize each facet's `id` member the first time an instance of the facet is installed into a locale. This depends only on static storage being zero before constructors run (3.1937.1). — *end note*]

22.14.0.1 `locale` constructors and destructor [locale.cons]

`locale() noexcept;`

1

Default constructor: a snapshot of the current global locale.

1

Effects: Constructs a copy of the argument last passed to `locale::global(locale&)`, if it has been called; else, the resulting facets have virtual function semantics identical to those of `locale::classic()`. [*Note:* This constructor is commonly used as the default value for arguments of functions that take a `const locale&` argument. — *end note*]

`locale(const locale& other) noexcept;`

1 *Effects:* Constructs a locale which is a copy of `other`.

`explicit locale(const char* std_name);`

2

Effects: Constructs a locale using standard C locale names, e.g., `"POSIX"`. The resulting locale implements semantics defined to be associated with that name.

1

Throws: `runtime_error` if the argument is not valid, or is null.

1

Remarks: The set of valid string argument values is `"C"`, `""`, and any implementation-defined values.

`explicit locale(const string& std_name);`

1 *Effects:* The same as `locale(std_name.c_str())`.

`locale(const locale& other, const char* std_name, category);`

2 *Effects:* Constructs a locale as a copy of `other` except for the facets identified by the `category` argument, which instead implement the same semantics as `locale(std_name)`.

3 *Throws:* `runtime_error` if the argument is not valid, or is null.

4 *Remarks:* The locale has a name if and only if `other` has a name.

`locale(const locale& other, const string& std_name, category cat);`

5 *Effects:* The same as `locale(other, std_name.c_str(), cat)`.

```
template <class Facet> locale(const locale& other, Facet* f);
```

6 *Effects:* Constructs a locale incorporating all facets from the first argument except that of type `Facet`, and installs the second argument as the remaining facet. If `f` is null, the resulting object is a copy of `other`.

7 *Remarks:* The resulting locale has no name.

```
locale(const locale& other, const locale& one, category cats);
```

8 *Effects:* Constructs a locale incorporating all facets from the first argument except those that implement `cats`, which are instead incorporated from the second argument.

9 *Remarks:* The resulting locale has a name if and only if the first two arguments have names.

```
const locale& operator=(const locale& other) noexcept;
```

10 *Effects:* Creates a copy of `other`, replacing the current value.

11 *Returns:* `*this`

```
~locale();
```

12 A non-virtual destructor that throws no exceptions.

22.20.0.1 `locale` members [locale.members]

```
template <class Facet> locale combine(const locale& other) const;
```

1 *Effects:* Constructs a locale incorporating all facets from `*this` except for that one facet of `other` that is identified by `Facet`.

2 *Returns:* The newly created locale.

3 *Throws:* `runtime_error` if `has_facet<Facet>(other)` is false.

4 *Remarks:* The resulting locale has no name.

```
basic_string<char> name() const;
```

5 *Returns:* The name of `*this`, if it has one; otherwise, the string `"*"`. If `*this` has a name, then `locale(name().c_str())` is equivalent to `*this`. Details of the contents of the resulting string are otherwise implementation-defined.

22.20.0.2 `locale` operators [locale.operators]

```
bool operator==(const locale& other) const;
```

1 *Returns:* `true` if both arguments are the same locale, or one is a copy of the other, or each has a name and the names are identical; `false` otherwise.

```
bool operator!=(const locale& other) const;
```

2 *Returns:* The result of the expression: `!(*this == other)`.

```
template <class charT, class traits, class Allocator>
  bool operator()(const basic_string<charT,traits,Allocator>& s1,
                  const basic_string<charT,traits,Allocator>& s2) const;
```

3 *Effects:* Compares two strings according to the `collate<charT>` facet.

4 *Remarks:* This member operator template (and therefore `locale` itself) satisfies requirements for a comparator predicate template argument (Clause 25) applied to strings.

5 *Returns:* The result of the following expression:

```
use_facet< collate<charT> >(*this).compare
  (s1.data(), s1.data()+s1.size(), s2.data(), s2.data()+s2.size()) < 0;
```

6 [*Example:* A vector of strings `v` can be collated according to collation rules in locale `loc` simply by (25.144.1, 23.696.1):

```
std::sort(v.begin(), v.end(), loc);
```

— *end example*]

22.20.0.3 `locale` static members [locale.statics]

`static locale global(const locale& loc);`

1

Sets the global locale to its argument.

1

Effects: Causes future calls to the constructor `locale()` to return a copy of the argument. If the argument has a name, does

```
std::setlocale(LC_ALL, loc.name().c_str());
```

otherwise, the effect on the C locale, if any, is implementation-defined. No library function other than `locale::global()` shall affect the value returned by `locale()`. [*Note:* See 22.118 for data race considerations when `setlocale` is invoked. — *end note*]

1

Returns: The previous value of `locale()`.

`static const locale& classic();`

1 The `"C"` locale.

2

Returns: A locale that implements the classic `"C"` locale semantics, equivalent to the value `locale("C")`.

1

Remarks: This locale, its facets, and their member functions, do not change with time.

22.25.1 `locale` globals [locale.global.templates]

`template <class Facet> const Facet& use_facet(const locale& loc);`

1 *Requires:* `Facet` is a facet class whose definition contains the public static member `id` as defined in 22.6.0.1.2.

2 *Returns:* A reference to the corresponding facet of `loc`, if present.

3 *Throws:* `bad_cast` if `has_facet<Facet>(loc)` is `false`.

4 *Remarks:* The reference returned remains valid at least as long as any copy of `loc` exists.

`template <class Facet> bool has_facet(const locale& loc) noexcept;`

5 *Returns:* True if the facet requested is present in `loc`; otherwise false.

22.25.2 Convenience interfaces [locale.convenience]

22.25.2.1 Character classification [classification]

```
template <class charT> bool isspace (charT c, const locale& loc);
template <class charT> bool isprint (charT c, const locale& loc);
template <class charT> bool iscntrl (charT c, const locale& loc);
template <class charT> bool isupper (charT c, const locale& loc);
template <class charT> bool islower (charT c, const locale& loc);
template <class charT> bool isalpha (charT c, const locale& loc);
template <class charT> bool isdigit (charT c, const locale& loc);
template <class charT> bool ispunct (charT c, const locale& loc);
template <class charT> bool isxdigit(charT c, const locale& loc);
template <class charT> bool isalnum (charT c, const locale& loc);
template <class charT> bool isgraph (charT c, const locale& loc);
template <class charT> bool isblank (charT c, const locale& loc);
```

1

Each of these functions `is`***F*** returns the result of the expression:

```
use_facet< ctype<charT> >(loc).is(ctype_base::F, c)
```

where ***F*** is the `ctype_base::mask` value corresponding to that function (22.31.1).[238]

22.26.0.1 Conversions [conversions]

22.26.0.1.1 Character conversions [conversions.character]

```
template <class charT> charT toupper(charT c, const locale& loc);
```

1

Returns: `use_facet<ctype<charT> >(loc).toupper(c)`.

```
template <class charT> charT tolower(charT c, const locale& loc);
```

1 *Returns:* `use_facet<ctype<charT> >(loc).tolower(c)`.

22.27.0.0.1 `string` conversions [conversions.string]

1

Class template `wstring_convert` performs conversions between a wide string and a byte string. It lets you specify a code conversion facet (like class template `codecvt`) to perform the conversions, without affecting any streams or locales. [*Example:* If you want to use the code conversion facet `codecvt_utf8` to output to `cout` a UTF-8 multibyte sequence corresponding to a wide string, but you don't want to alter the locale for `cout`, you can write something like:

```
wstring_convert<std::codecvt_utf8<wchar_t>> myconv;
std::string mbstring = myconv.to_bytes(L"Hello\n");
std::cout << mbstring;
```

— *end example*]

1 **Class template `wstring_convert` synopsis**

```
namespace std {
template<class Codecvt, class Elem = wchar_t,
    class Wide_alloc = std::allocator<Elem>,
    class Byte_alloc = std::allocator<char> > class wstring_convert {
```

238) When used in a loop, it is faster to cache the `ctype<>` facet and use it directly, or use the vector form of `ctype<>::is`.

```
  public:
    typedef std::basic_string<char, char_traits<char>, Byte_alloc> byte_string;
    typedef std::basic_string<Elem, char_traits<Elem>, Wide_alloc> wide_string;
    typedef typename Codecvt::state_type state_type;
    typedef typename wide_string::traits_type::int_type int_type;

    explicit wstring_convert(Codecvt* pcvt = new Codecvt);
    wstring_convert(Codecvt* pcvt, state_type state);
    explicit wstring_convert(const byte_string& byte_err,
                             const wide_string& wide_err = wide_string());
    ~wstring_convert();

    wstring_convert(const wstring_convert&) = delete;
    wstring_convert& operator=(const wstring_convert&) = delete;

    wide_string from_bytes(char byte);
    wide_string from_bytes(const char* ptr);
    wide_string from_bytes(const byte_string& str);
    wide_string from_bytes(const char* first, const char* last);

    byte_string to_bytes(Elem wchar);
    byte_string to_bytes(const Elem* wptr);
    byte_string to_bytes(const wide_string& wstr);
    byte_string to_bytes(const Elem* first, const Elem* last);

    size_t converted() const noexcept;
    state_type state() const;
  private:
    byte_string byte_err_string;    // exposition only
    wide_string wide_err_string;    // exposition only
    Codecvt* cvtptr;                // exposition only
    state_type cvtstate;            // exposition only
    size_t cvtcount;                // exposition only
  };
}
```

2 The class template describes an object that controls conversions between wide string objects of class `std::basic_string<Elem, char_traits<Elem>, Wide_alloc>` and byte string objects of class `std::basic_string<char, char_traits<char>, Byte_alloc>`. The class template defines the types `wide_string` and `byte_string` as synonyms for these two types. Conversion between a sequence of `Elem` values (stored in a `wide_string` object) and multibyte sequences (stored in a `byte_string` object) is performed by an object of class `Codecvt`, which meets the requirements of the standard code-conversion facet `std::codecvt<Elem, char, std::mbstate_t>`.

3 An object of this class template stores:

(3.1) — `byte_err_string` — a byte string to display on errors

(3.2) — `wide_err_string` — a wide string to display on errors

(3.3) — `cvtptr` — a pointer to the allocated conversion object (which is freed when the `wstring_convert` object is destroyed)

(3.4) — `cvtstate` — a conversion state object

(3.5) — `cvtcount` — a conversion count

```
typedef std::basic_string<char, char_traits<char>, Byte_alloc> byte_string;
```

4 The type shall be a synonym for `std::basic_string<char, char_traits<char>, Byte_alloc>`

```
size_t converted() const noexcept;
```

5 *Returns:* `cvtcount`.

```
wide_string from_bytes(char byte);
wide_string from_bytes(const char* ptr);
wide_string from_bytes(const byte_string& str);
wide_string from_bytes(const char* first, const char* last);
```

6 *Effects:* The first member function shall convert the single-element sequence `byte` to a wide string. The second member function shall convert the null-terminated sequence beginning at `ptr` to a wide string. The third member function shall convert the sequence stored in `str` to a wide string. The fourth member function shall convert the sequence defined by the range `[first,last)` to a wide string.

7 In all cases:

(7.1) — If the `cvtstate` object was not constructed with an explicit value, it shall be set to its default value (the initial conversion state) before the conversion begins. Otherwise it shall be left unchanged.

(7.2) — The number of input elements successfully converted shall be stored in `cvtcount`.

8

Returns: If no conversion error occurs, the member function shall return the converted wide string. Otherwise, if the object was constructed with a wide-error string, the member function shall return the wide-error string. Otherwise, the member function throws an object of class `std::range_error`.

```
typedef typename wide_string::traits_type::int_type int_type;
```

The type shall be a synonym for `wide_string::traits_type::int_type`.

```
state_type state() const;
```

1 returns `cvtstate`.

```
typedef typename Codecvt::state_type state_type;
```

2 The type shall be a synonym for `Codecvt::state_type`.

```
byte_string to_bytes(Elem wchar);
byte_string to_bytes(const Elem* wptr);
byte_string to_bytes(const wide_string& wstr);
byte_string to_bytes(const Elem* first, const Elem* last);
```

3 *Effects:* The first member function shall convert the single-element sequence `wchar` to a byte string. The second member function shall convert the null-terminated sequence beginning at `wptr` to a byte string. The third member function shall convert the sequence stored in `wstr` to a byte string. The fourth member function shall convert the sequence defined by the range `[first,last)` to a byte string.

4 In all cases:

(4.1) — If the `cvtstate` object was not constructed with an explicit value, it shall be set to its default value (the initial conversion state) before the conversion begins. Otherwise it shall be left unchanged.

(4.2) — The number of input elements successfully converted shall be stored in `cvtcount`.

5 *Returns:* If no conversion error occurs, the member function shall return the converted byte string. Otherwise, if the object was constructed with a byte-error string, the member function shall return the byte-error string. Otherwise, the member function shall throw an object of class `std::range_error`.

```
typedef std::basic_string<Elem, char_traits<Elem>, Wide_alloc> wide_string;
```

6 The type shall be a synonym for `std::basic_string<Elem, char_traits<Elem>, Wide_alloc>`.

```
explicit wstring_convert(Codecvt* pcvt = new Codecvt);
wstring_convert(Codecvt* pcvt, state_type state);
explicit wstring_convert(const byte_string& byte_err,
    const wide_string& wide_err = wide_string());
```

7 *Requires:* For the first and second constructors, `pcvt != nullptr`.

8 *Effects:* The first constructor shall store `pcvt` in `cvtptr` and default values in `cvtstate`, `byte_err_string`, and `wide_err_string`. The second constructor shall store `pcvt` in `cvtptr`, `state` in `cvtstate`, and default values in `byte_err_string` and `wide_err_string`; moreover the stored state shall be retained between calls to `from_bytes` and `to_bytes`. The third constructor shall store `new Codecvt` in `cvtptr`, `state_type()` in `cvtstate`, `byte_err` in `byte_err_string`, and `wide_err` in `wide_err_string`.

```
~wstring_convert();
```

9 *Effects:* The destructor shall delete `cvtptr`.

22.30.0.0.1 Buffer conversions [conversions.buffer]

1 Class template `wbuffer_convert` looks like a wide stream buffer, but performs all its I/O through an underlying byte stream buffer that you specify when you construct it. Like class template `wstring_convert`, it lets you specify a code conversion facet to perform the conversions, without affecting any streams or locales.

2 **Class template `wbuffer_convert` synopsis**

```
namespace std {
template<class Codecvt,
    class Elem = wchar_t,
    class Tr = std::char_traits<Elem> >
  class wbuffer_convert
    : public std::basic_streambuf<Elem, Tr> {
  public:
    typedef typename Codecvt::state_type state_type;

    explicit wbuffer_convert(std::streambuf* bytebuf = 0,
                             Codecvt* pcvt = new Codecvt,
                             state_type state = state_type());

    ~wbuffer_convert();

    wbuffer_convert(const wbuffer_convert&) = delete;
    wbuffer_convert& operator=(const wbuffer_convert&) = delete;

    std::streambuf* rdbuf() const;
    std::streambuf* rdbuf(std::streambuf* bytebuf);

    state_type state() const;

  private:
    std::streambuf* bufptr;          // exposition only
    Codecvt* cvtptr;                 // exposition only
    state_type cvtstate;             // exposition only
  };
}
```

3 The class template describes a stream buffer that controls the transmission of elements of type `Elem`, whose character traits are described by the class `Tr`, to and from a byte stream buffer of type `std::streambuf`. Conversion between a sequence of `Elem` values and multibyte sequences is performed by an object of class `Codecvt`, which shall meet the requirements of the standard code-conversion facet `std::codecvt<Elem, char, std::mbstate_t>`.

4 An object of this class template stores:

(4.1) — `bufptr` — a pointer to its underlying byte stream buffer

(4.2) — `cvtptr` — a pointer to the allocated conversion object (which is freed when the `wbuffer_convert` object is destroyed)

(4.3) — `cvtstate` — a conversion state object

```
state_type state() const;
```

5 *Returns:* `cvtstate`.

```
std::streambuf* rdbuf() const;
```

6 *Returns:* `bufptr`.

```
std::streambuf* rdbuf(std::streambuf* bytebuf);
```

7 *Effects:* stores `bytebuf` in `bufptr`.

8 *Returns:* The previous value of `bufptr`.

```
typedef typename Codecvt::state_type state_type;
```

9 The type shall be a synonym for `Codecvt::state_type`.

```
explicit wbuffer_convert(std::streambuf* bytebuf = 0,
    Codecvt* pcvt = new Codecvt, state_type state = state_type());
```

10 *Requires:* `pcvt != nullptr`.

11 *Effects:* The constructor constructs a stream buffer object, initializes `bufptr` to `bytebuf`, initializes `cvtptr` to `pcvt`, and initializes `cvtstate` to `state`.

```
~wbuffer_convert();
```

12 *Effects:* The destructor shall delete `cvtptr`.

22.31 Standard `locale` categories [locale.categories]

1 Each of the standard categories includes a family of facets. Some of these implement formatting or parsing of a datum, for use by standard or users' iostream operators `<<` and `>>`, as members `put()` and `get()`, respectively. Each such member function takes an `ios_base&` argument whose members `flags()`, `precision()`, and `width()`, specify the format of the corresponding datum (27.58.1). Those functions which need to use other facets call its member `getloc()` to retrieve the locale imbued there. Formatting facets use the character argument `fill` to fill out the specified width where necessary.

2 The `put()` members make no provision for error reporting. (Any failures of the OutputIterator argument must be extracted from the returned iterator.) The `get()` members take an `ios_base::iostate&` argument whose value they ignore, but set to `ios_base::failbit` in case of a parse error.

3 Within this clause it is unspecified whether one virtual function calls another virtual function.

22.31.1 The ctype category [category.ctype]

```
namespace std {
  class ctype_base {
  public:
    typedef T mask;

    // numeric values are for exposition only.
    static const mask space = 1 << 0;
    static const mask print = 1 << 1;
    static const mask cntrl = 1 << 2;
    static const mask upper = 1 << 3;
    static const mask lower = 1 << 4;
    static const mask alpha = 1 << 5;
    static const mask digit = 1 << 6;
    static const mask punct = 1 << 7;
    static const mask xdigit = 1 << 8;
    static const mask blank = 1 << 9;
    static const mask alnum = alpha | digit;
    static const mask graph = alnum | punct;
  };
}
```

1 The type mask is a bitmask type (17.20.0.0.1).

22.31.1.1 Class template ctype [locale.ctype]

```
namespace std {
  template <class charT>
  class ctype : public locale::facet, public ctype_base {
  public:
    typedef charT char_type;

    explicit ctype(size_t refs = 0);

    bool         is(mask m, charT c) const;
    const charT* is(const charT* low, const charT* high, mask* vec) const;
    const charT* scan_is(mask m,
                         const charT* low, const charT* high) const;
    const charT* scan_not(mask m,
                          const charT* low, const charT* high) const;
    charT        toupper(charT c) const;
    const charT* toupper(charT* low, const charT* high) const;
    charT        tolower(charT c) const;
    const charT* tolower(charT* low, const charT* high) const;

    charT        widen(char c) const;
    const char*  widen(const char* low, const char* high, charT* to) const;
    char         narrow(charT c, char dfault) const;
    const charT* narrow(const charT* low, const charT*, char dfault,
                        char* to) const;

    static locale::id id;

  protected:
   ~ctype();
    virtual bool         do_is(mask m, charT c) const;
```

```
    virtual const charT* do_is(const charT* low, const charT* high,
                               mask* vec) const;
    virtual const charT* do_scan_is(mask m,
                                    const charT* low, const charT* high) const;
    virtual const charT* do_scan_not(mask m,
                                     const charT* low, const charT* high) const;
    virtual charT        do_toupper(charT) const;
    virtual const charT* do_toupper(charT* low, const charT* high) const;
    virtual charT        do_tolower(charT) const;
    virtual const charT* do_tolower(charT* low, const charT* high) const;
    virtual charT        do_widen(char) const;
    virtual const char*  do_widen(const char* low, const char* high,
                                  charT* dest) const;
    virtual char         do_narrow(charT, char dfault) const;
    virtual const charT* do_narrow(const charT* low, const charT* high,
                                   char dfault, char* dest) const;
  };
}
```

1 Class `ctype` encapsulates the C library `<cctype>` features. `istream` members are required to use `ctype<>` for character classing during input parsing.

2 The specializations required in Table 81 (22.6.0.1.1), namely `ctype<char>` and `ctype<wchar_t>`, implement character classing appropriate to the implementation's native character set.

22.31.1.1.1 `ctype` members [locale.ctype.members]

```
bool         is(mask m, charT c) const;
const charT* is(const charT* low, const charT* high,
                mask* vec) const;
```

1 *Returns:* `do_is(m,c)` or `do_is(low,high,vec)`

```
const charT* scan_is(mask m,
                     const charT* low, const charT* high) const;
```

2 *Returns:* `do_scan_is(m,low,high)`

```
const charT* scan_not(mask m,
                      const charT* low, const charT* high) const;
```

3 *Returns:* `do_scan_not(m,low,high)`

```
charT        toupper(charT) const;
const charT* toupper(charT* low, const charT* high) const;
```

4 *Returns:* `do_toupper(c)` or `do_toupper(low,high)`

```
charT        tolower(charT c) const;
const charT* tolower(charT* low, const charT* high) const;
```

5 *Returns:* `do_tolower(c)` or `do_tolower(low,high)`

```
charT       widen(char c) const;
const char* widen(const char* low, const char* high, charT* to) const;
```

6 *Returns:* `do_widen(c)` or `do_widen(low,high,to)`

```
char         narrow(charT c, char dfault) const;
const charT* narrow(const charT* low, const charT*, char dfault,
                    char* to) const;
```

7 *Returns:* `do_narrow(c,dfault)` or `do_narrow(low,high,dfault,to)`

22.31.1.1.2 `ctype` virtual functions [locale.ctype.virtuals]

```
bool         do_is(mask m, charT c) const;
const charT* do_is(const charT* low, const charT* high,
                   mask* vec) const;
```

1 *Effects:* Classifies a character or sequence of characters. For each argument character, identifies a value `M` of type `ctype_base::mask`. The second form identifies a value `M` of type `ctype_base::mask` for each `*p` where `(low<=p && p<high)`, and places it into `vec[p-low]`.

2 *Returns:* The first form returns the result of the expression `(M & m) != 0`; i.e., `true` if the character has the characteristics specified. The second form returns `high`.

```
const charT* do_scan_is(mask m,
                        const charT* low, const charT* high) const;
```

3 *Effects:* Locates a character in a buffer that conforms to a classification `m`.

4 *Returns:* The smallest pointer `p` in the range `[low, high)` such that `is(m,*p)` would return `true`; otherwise, returns `high`.

```
const charT* do_scan_not(mask m,
                         const charT* low, const charT* high) const;
```

5 *Effects:* Locates a character in a buffer that fails to conform to a classification `m`.

6 *Returns:* The smallest pointer `p`, if any, in the range `[low,high)` such that `is(m,*p)` would return `false`; otherwise, returns `high`.

```
charT        do_toupper(charT c) const;
const charT* do_toupper(charT* low, const charT* high) const;
```

7 *Effects:* Converts a character or characters to upper case. The second form replaces each character `*p` in the range `[low,high)` for which a corresponding upper-case character exists, with that character.

8 *Returns:* The first form returns the corresponding upper-case character if it is known to exist, or its argument if not. The second form returns `high`.

```
charT        do_tolower(charT c) const;
const charT* do_tolower(charT* low, const charT* high) const;
```

9 *Effects:* Converts a character or characters to lower case. The second form replaces each character `*p` in the range `[low,high)` and for which a corresponding lower-case character exists, with that character.

10 *Returns:* The first form returns the corresponding lower-case character if it is known to exist, or its argument if not. The second form returns `high`.

```
charT        do_widen(char c) const;
const char*  do_widen(const char* low, const char* high,
                      charT* dest) const;
```

11 *Effects:* Applies the simplest reasonable transformation from a `char` value or sequence of `char` values to the corresponding `charT` value or values.[239] The only characters for which unique transformations are required are those in the basic source character set (2.154).

For any named `ctype` category with a `ctype<charT>` facet `ctc` and valid `ctype_base::mask` value `M`, `(ctc.is(M, c) || !is(M, do_widen(c)) )` is `true`.[240]

The second form transforms each character `*p` in the range `[low,high)`, placing the result in `dest[p-low]`.

12 *Returns:* The first form returns the transformed value. The second form returns `high`.

```
char         do_narrow(charT c, char dfault) const;
const charT* do_narrow(const charT* low, const charT* high,
                       char dfault, char* dest) const;
```

13 *Effects:* Applies the simplest reasonable transformation from a `charT` value or sequence of `charT` values to the corresponding `char` value or values.

For any character `c` in the basic source character set (2.154) the transformation is such that

```
do_widen(do_narrow(c,0)) == c
```

For any named `ctype` category with a `ctype<char>` facet `ctc` however, and `ctype_base::mask` value `M`,

```
(is(M,c) || !ctc.is(M, do_narrow(c,dfault)) )
```

is `true` (unless `do_narrow` returns `dfault`). In addition, for any digit character `c`, the expression `(do_narrow(c, dfault) - '0')` evaluates to the digit value of the character. The second form transforms each character `*p` in the range `[low,high)`, placing the result (or `dfault` if no simple transformation is readily available) in `dest[p-low]`.

14 *Returns:* The first form returns the transformed value; or `dfault` if no mapping is readily available. The second form returns `high`.

22.31.1.2 Class template `ctype_byname` [locale.ctype.byname]

```
namespace std {
  template <class charT>
  class ctype_byname : public ctype<charT> {
  public:
    typedef typename ctype<charT>::mask mask;
    explicit ctype_byname(const char*, size_t refs = 0);
    explicit ctype_byname(const string&, size_t refs = 0);
  protected:
   ~ctype_byname();
  };
}
```

22.31.1.3 `ctype` specializations [facet.ctype.special]

```
namespace std {
  template <> class ctype<char>
    : public locale::facet, public ctype_base {
  public:
    typedef char char_type;
```

239) The char argument of `do_widen` is intended to accept values derived from character literals for conversion to the locale's encoding.

240) In other words, the transformed character is not a member of any character classification that `c` is not also a member of.

```
    explicit ctype(const mask* tab = 0, bool del = false,
                   size_t refs = 0);

    bool is(mask m, char c) const;
    const char* is(const char* low, const char* high, mask* vec) const;
    const char* scan_is (mask m,
                         const char* low, const char* high) const;
    const char* scan_not(mask m,
                         const char* low, const char* high) const;

    char        toupper(char c) const;
    const char* toupper(char* low, const char* high) const;
    char        tolower(char c) const;
    const char* tolower(char* low, const char* high) const;

    char  widen(char c) const;
    const char* widen(const char* low, const char* high, char* to) const;
    char  narrow(char c, char dfault) const;
    const char* narrow(const char* low, const char* high, char dfault,
                       char* to) const;

    static locale::id id;
    static const size_t table_size = implementation-defined;

    const mask* table() const noexcept;
    static const mask* classic_table() noexcept;

  protected:
   ~ctype();
    virtual char        do_toupper(char c) const;
    virtual const char* do_toupper(char* low, const char* high) const;
    virtual char        do_tolower(char c) const;
    virtual const char* do_tolower(char* low, const char* high) const;

    virtual char        do_widen(char c) const;
    virtual const char* do_widen(const char* low,
                                 const char* high,
                                 char* to) const;
    virtual char        do_narrow(char c, char dfault) const;
    virtual const char* do_narrow(const char* low,
                                  const char* high,
                                  char dfault, char* to) const;
  };
}
```

1 A specialization `ctype<char>` is provided so that the member functions on type `char` can be implemented `inline`.[241] The implementation-defined value of member `table_size` is at least 256.

22.31.1.3.1 `ctype<char>` destructor [facet.ctype.char.dtor]

```
~ctype();
```

241) Only the `char` (not `unsigned char` and `signed char`) form is provided. The specialization is specified in the standard, and not left as an implementation detail, because it affects the derivation interface for `ctype<char>`.

1 *Effects:* If the constructor's first argument was nonzero, and its second argument was true, does `delete [] table()`.

22.31.1.3.2 `ctype<char>` members [facet.ctype.char.members]

1 In the following member descriptions, for `unsigned char` values `v` where `v >= table_size`, `table()[v]` is assumed to have an implementation-specific value (possibly different for each such value `v`) without performing the array lookup.

```
explicit ctype(const mask* tbl = 0, bool del = false,
               size_t refs = 0);
```

2 *Requires:* `tbl` either 0 or an array of at least `table_size` elements.

3 *Effects:* Passes its `refs` argument to its base class constructor.

```
bool        is(mask m, char c) const;
const char* is(const char* low, const char* high,
               mask* vec) const;
```

4 *Effects:* The second form, for all `*p` in the range `[low,high)`, assigns into `vec[p-low]` the value `table()[(unsigned char)*p]`.

5 *Returns:* The first form returns `table()[(unsigned char)c] & m`; the second form returns `high`.

```
const char* scan_is(mask m,
                    const char* low, const char* high) const;
```

6 *Returns:* The smallest `p` in the range `[low,high)` such that

```
table()[(unsigned char) *p] & m
```

is `true`.

```
const char* scan_not(mask m,
                     const char* low, const char* high) const;
```

7 *Returns:* The smallest `p` in the range `[low,high)` such that

```
table()[(unsigned char) *p] & m
```

is `false`.

```
char        toupper(char c) const;
const char* toupper(char* low, const char* high) const;
```

8 *Returns:* `do_toupper(c)` or `do_toupper(low,high)`, respectively.

```
char        tolower(char c) const;
const char* tolower(char* low, const char* high) const;
```

9 *Returns:* `do_tolower(c)` or `do_tolower(low,high)`, respectively.

```
char  widen(char c) const;
const char* widen(const char* low, const char* high,
    char* to) const;
```

10 *Returns:* `do_widen(c)` or `do_widen(low, high, to)`, respectively.

```
char        narrow(char c, char dfault) const;
const char* narrow(const char* low, const char* high,
                   char dfault, char* to) const;
```

1 *Returns:* `do_narrow(c, dfault)` or `do_narrow(low, high, dfault, to)`, respectively.

```
const mask* table() const noexcept;
```

2 *Returns:* The first constructor argument, if it was non-zero, otherwise `classic_table()`.

22.32.0.0.1 `ctype<char>` static members [facet.ctype.char.statics]

```
static const mask* classic_table() noexcept;
```

1

Returns: A pointer to the initial element of an array of size `table_size` which represents the classifications of characters in the "C" locale.

22.34.0.0.1 `ctype<char>` virtual functions [facet.ctype.char.virtuals]

```
char        do_toupper(char) const;
const char* do_toupper(char* low, const char* high) const;
char        do_tolower(char) const;
const char* do_tolower(char* low, const char* high) const;

virtual char        do_widen(char c) const;
virtual const char* do_widen(const char* low,
                             const char* high,
                             char* to) const;
virtual char        do_narrow(char c, char dfault) const;
virtual const char* do_narrow(const char* low,
                              const char* high,
                              char dfault, char* to) const;
```

These functions are described identically as those members of the same name in the `ctype` class template (22.31.1.1.1).

22.34.0.1 Class template `codecvt` [locale.codecvt]

```
namespace std {
  class codecvt_base {
  public:
    enum result { ok, partial, error, noconv };
  };

  template <class internT, class externT, class stateT>
  class codecvt : public locale::facet, public codecvt_base {
  public:
    typedef internT  intern_type;
    typedef externT  extern_type;
    typedef stateT state_type;

    explicit codecvt(size_t refs = 0);

    result out(stateT& state,
               const internT* from, const internT* from_end, const internT*& from_next,
               externT*   to,       externT* to_end, externT*& to_next) const;
    result unshift(stateT& state,
```

```
                externT*   to,        externT* to_end, externT*& to_next) const;
  result in(stateT& state,
            const externT* from, const externT* from_end, const externT*& from_next,
            internT*   to,       internT* to_end, internT*& to_next) const;
  int encoding() const noexcept;
  bool always_noconv() const noexcept;
  int length(stateT&, const externT* from, const externT* end,
             size_t max) const;
  int max_length() const noexcept;

  static locale::id id;

protected:
  ~codecvt();
  virtual result do_out(stateT& state,
                        const internT* from, const internT* from_end, const internT*& from_next,
                        externT* to,         externT* to_end, externT*& to_next) const;
  virtual result do_in(stateT& state,
                       const externT* from, const externT* from_end, const externT*& from_next,
                       internT* to,         internT* to_end, internT*& to_next) const;
  virtual result do_unshift(stateT& state,
                            externT* to,         externT* to_end, externT*& to_next) const;
  virtual int do_encoding() const noexcept;
  virtual bool do_always_noconv() const noexcept;
  virtual int do_length(stateT&, const externT* from,
                        const externT* end, size_t max) const;
  virtual int do_max_length() const noexcept;
};
}
```

1

The class `codecvt<internT,externT,stateT>` is for use when converting from one character encoding to another, such as from wide characters to multibyte characters or between wide character encodings such as Unicode and EUC.

1 The `stateT` argument selects the pair of character encodings being mapped between.

2

The specializations required in Table 81 (22.6.0.1.1) convert the implementation-defined native character set. `codecvt<char, char, mbstate_t>` implements a degenerate conversion; it does not convert at all. The specialization `codecvt<char16_t, char, mbstate_t>` converts between the UTF-16 and UTF-8 encoding forms, and the specialization `codecvt <char32_t, char, mbstate_t>` converts between the UTF-32 and UTF-8 encoding forms. `codecvt<wchar_t,char,mbstate_t>` converts between the native character sets for narrow and wide characters. Specializations on `mbstate_t` perform conversion between encodings known to the library implementer. Other encodings can be converted by specializing on a user-defined `stateT` type. Objects of type `stateT` can contain any state that is useful to communicate to or from the specialized `do_in` or `do_out` members.

22.39.0.0.1 `codecvt` members [locale.codecvt.members]

```
result out(stateT& state,
  const internT* from, const internT* from_end, const internT*& from_next,
        externT* to, externT* to_end, externT*& to_next) const;
```

1 *Returns:* `do_out(state, from, from_end, from_next, to, to_end, to_next)`

```
result unshift(stateT& state,
        externT* to, externT* to_end, externT*& to_next) const;
```

2

Returns: `do_unshift(state, to, to_end, to_next)`

```
result in(stateT& state,
  const externT* from, const externT* from_end, const externT*& from_next,
        internT* to, internT* to_end, internT*& to_next) const;
```

1 *Returns:* `do_in(state, from, from_end, from_next, to, to_end, to_next)`

```
int encoding() const noexcept;
```

2 *Returns:* `do_encoding()`

```
bool always_noconv() const noexcept;
```

3 *Returns:* `do_always_noconv()`

```
int length(stateT& state, const externT* from, const externT* from_end,
           size_t max) const;
```

4 *Returns:* `do_length(state, from,from_end,max)`

```
int max_length() const noexcept;
```

5 *Returns:* `do_max_length()`

22.41.0.0.1 `codecvt` virtual functions [locale.codecvt.virtuals]

```
result do_out(stateT& state,
  const internT* from, const internT* from_end, const internT*& from_next,
  externT* to, externT* to_end, externT*& to_next) const;

result do_in(stateT& state,
  const externT* from, const externT* from_end, const externT*& from_next,
        internT* to, internT* to_end, internT*& to_next) const;
```

1 *Requires:* `(from<=from_end && to<=to_end)` well-defined and `true`; `state` initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

2 *Effects:* Translates characters in the source range `[from,from_end)`, placing the results in sequential positions starting at destination `to`. Converts no more than `(from_end-from)` source elements, and stores no more than `(to_end-to)` destination elements.

Stops if it encounters a character it cannot convert. It always leaves the `from_next` and `to_next` pointers pointing one beyond the last element successfully converted. If returns `noconv`, `internT` and `externT` are the same type and the converted sequence is identical to the input sequence `[from, from_next)`. `to_next` is set equal to `to`, the value of `state` is unchanged, and there are no changes to the values in `[to, to_end)`.

3

A `codecvt` facet that is used by `basic_filebuf` (27.248) shall have the property that if

```
do_out(state, from, from_end, from_next, to, to_end, to_next)
```

would return `ok`, where `from != from_end`, then

```
do_out(state, from, from + 1, from_next, to, to_end, to_next)
```

shall also return `ok`, and that if

```
do_in(state, from, from_end, from_next, to, to_end, to_next)
```

would return `ok`, where `to != to_end`, then

```
do_in(state, from, from_end, from_next, to, to + 1, to_next)
```

shall also return `ok`.[242] [*Note:* As a result of operations on `state`, it can return `ok` or `partial` and set `from_next == from` and `to_next != to`. — *end note*]

1 *Remarks:* Its operations on `state` are unspecified. [*Note:* This argument can be used, for example, to maintain shift state, to specify conversion options (such as count only), or to identify a cache of seek offsets. — *end note*]

2 *Returns:* An enumeration value, as summarized in Table 83.

Table 83 — `do_in/do_out` result values

Value	Meaning
`ok`	completed the conversion
`partial`	not all source characters converted
`error`	encountered a character in `[from,from_end)` that it could not convert
`noconv`	`internT` and `externT` are the same type, and input sequence is identical to converted sequence

A return value of `partial`, if `(from_next==from_end)`, indicates that either the destination sequence has not absorbed all the available destination elements, or that additional source elements are needed before another destination element can be produced.

```
result do_unshift(stateT& state,
  externT* to, externT* to_end, externT*& to_next) const;
```

1 *Requires:* `(to <= to_end)` well defined and true; state initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

2 *Effects:* Places characters starting at `to` that should be appended to terminate a sequence when the current `stateT` is given by `state`.[243] Stores no more than `(to_end-to)` destination elements, and leaves the `to_next` pointer pointing one beyond the last element successfully stored.

3 *Returns:* An enumeration value, as summarized in Table 84.

```
int do_encoding() const noexcept;
```

4 *Returns:*-1 if the encoding of the `externT` sequence is state-dependent; else the constant number of `externT` characters needed to produce an internal character; or 0 if this number is not a constant.[244]

```
bool do_always_noconv() const noexcept;
```

242) Informally, this means that `basic_filebuf` assumes that the mappings from internal to external characters is 1 to N: a `codecvt` facet that is used by `basic_filebuf` must be able to translate characters one internal character at a time.
243) Typically these will be characters to return the state to `stateT()`
244) If `encoding()` yields -1, then more than `max_length()` `externT` elements may be consumed when producing a single `internT` character, and additional `externT` elements may appear at the end of a sequence after those that yield the final `internT` character.

Table 84 — `do_unshift` result values

Value	Meaning
`ok`	completed the sequence
`partial`	space for more than `to_end-to` destination elements was needed to terminate a sequence given the value of `state`
`error`	an unspecified error has occurred
`noconv`	no termination is needed for this `state_type`

5 *Returns:* `true` if `do_in()` and `do_out()` return `noconv` for all valid argument values. `codecvt<char, char, mbstate_t>` returns `true`.

```
int do_length(stateT& state, const externT* from, const externT* from_end,
              size_t max) const;
```

6 *Requires:* `(from<=from_end)` well-defined and `true`; `state` initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

7 *Effects:* The effect on the `state` argument is "as if" it called `do_in(state, from, from_end, from, to, to+max, to)` for `to` pointing to a buffer of at least `max` elements.

8 *Returns:* `(from_next-from)` where `from_next` is the largest value in the range `[from,from_end]` such that the sequence of values in the range `[from,from_next)` represents `max` or fewer valid complete characters of type `internT`. The specialization `codecvt<char, char, mbstate_t>`, returns the lesser of `max` and `(from_end-from)`.

```
int do_max_length() const noexcept;
```

9 *Returns:* The maximum value that `do_length(state, from, from_end, 1)` can return for any valid range `[from, from_end)` and `stateT` value `state`. The specialization `codecvt<char, char, mbstate_t>::do_max_length()` returns 1.

22.44.0.1 Class template `codecvt_byname` [locale.codecvt.byname]

```
namespace std {
  template <class internT, class externT, class stateT>
  class codecvt_byname : public codecvt<internT, externT, stateT> {
  public:
    explicit codecvt_byname(const char*, size_t refs = 0);
    explicit codecvt_byname(const string&, size_t refs = 0);
  protected:
    ~codecvt_byname();
  };
}
```

22.44.1 The numeric category [category.numeric]

1 The classes `num_get<>` and `num_put<>` handle numeric formatting and parsing. Virtual functions are provided for several numeric types. Implementations may (but are not required to) delegate extraction of smaller types to extractors for larger types.[245]

2

245) Parsing `"-1"` correctly into, e.g., an `unsigned short` requires that the corresponding member `get()` at least extract the sign before delegating.

All specifications of member functions for num_put and num_get in the subclauses of 22.44.1 only apply to the specializations required in Tables 81 and 82 (22.6.0.1.1), namely num_get<char>, num_get<wchar_t>, num_get<C, InputIterator>, num_put<char>, num_put<wchar_t>, and num_put<C,OutputIterator>. These specializations refer to the ios_base& argument for formatting specifications (22.31), and to its imbued locale for the numpunct<> facet to identify all numeric punctuation preferences, and also for the ctype<> facet to perform character classification.

1 Extractor and inserter members of the standard iostreams use num_get<> and num_put<> member functions for formatting and parsing numeric values (27.128.0.1.1, 27.198.0.1.1).

22.45.0.1 Class template num_get [locale.num.get]

```
namespace std {
  template <class charT, class InputIterator = istreambuf_iterator<charT> >
  class num_get : public locale::facet {
  public:
    typedef charT            char_type;
    typedef InputIterator    iter_type;

    explicit num_get(size_t refs = 0);

    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, bool& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, long& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, long long& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, unsigned short& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, unsigned int& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, unsigned long& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, unsigned long long& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, float& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, double& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, long double& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  ios_base::iostate& err, void*& v) const;

    static locale::id id;

  protected:
    ~num_get();
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, bool& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, long& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, long long& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, unsigned short& v) const;
```

```
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, unsigned int& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, unsigned long& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, unsigned long long& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, float& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, double& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, long double& v) const;
    virtual iter_type do_get(iter_type, iter_type, ios_base&,
                             ios_base::iostate& err, void*& v) const;
  };
}
```

1 The facet `num_get` is used to parse numeric values from an input sequence such as an istream.

22.45.0.1.1 `num_get` members [facet.num.get.members]

```
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, bool& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned short& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned int& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned long long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, float& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, void*& val) const;
```

1 *Returns:* `do_get(in, end, str, err, val)`.

22.45.0.1.2 `num_get` virtual functions [facet.num.get.virtuals]

```
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned short& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned int& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
```

```
  ios_base::iostate& err, unsigned long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned long long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, float& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, double& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long double& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, void*& val) const;
```

1 *Effects:* Reads characters from `in`, interpreting them according to `str.flags()`, `use_facet<ctype< charT> >(loc)`, and `use_facet< numpunct<charT> >(loc)`, where `loc` is `str.getloc()`.

2

The details of this operation occur in three stages

— Stage 1: Determine a conversion specifier

— Stage 2: Extract characters from `in` and determine a corresponding `char` value for the format expected by the conversion specification determined in stage 1.

— Stage 3: Store results

1

The details of the stages are presented below.

Stage 1: The function initializes local variables via

```
fmtflags flags = str .flags();
fmtflags basefield = (flags & ios_base::basefield);
fmtflags uppercase = (flags & ios_base::uppercase);
fmtflags boolalpha = (flags & ios_base::boolalpha);
```

For conversion to an integral type, the function determines the integral conversion specifier as indicated in Table 85. The table is ordered. That is, the first line whose condition is true applies.

Table 85 — Integer conversions

State	`stdio` equivalent
`basefield == oct`	`%o`
`basefield == hex`	`%X`
`basefield == 0`	`%i`
`signed` integral type	`%d`
`unsigned` integral type	`%u`

For conversions to a floating type the specifier is `%g`.

For conversions to `void*` the specifier is `%p`.

A length modifier is added to the conversion specification, if needed, as indicated in Table 86.

Stage 2: If `in==end` then stage 2 terminates. Otherwise a `charT` is taken from `in` and local variables are initialized as if by

```
char_type ct = *in ;
char c = src[find(atoms, atoms + sizeof(src) - 1, ct) - atoms];
if (ct ==  use_facet<numpunct<charT> >(loc).decimal_point())
c = '.';
bool discard =
  ct == use_facet<numpunct<charT> >(loc).thousands_sep()
  && use_facet<numpunct<charT> >(loc).grouping().length() != 0;
```

Table 86 — Length modifier

Type	Length modifier
short	h
unsigned short	h
long	l
unsigned long	l
long long	ll
unsigned long long	ll
double	l
long double	L

where the values `src` and `atoms` are defined as if by:

```
static const char src[] = "0123456789abcdefxABCDEFX+-";
char_type atoms[sizeof(src)];
use_facet<ctype<charT> >(loc).widen(src, src + sizeof(src), atoms);
```

for this value of `loc`.

If `discard` is true, then if `'.'` has not yet been accumulated, then the position of the character is remembered, but the character is otherwise ignored. Otherwise, if `'.'` has already been accumulated, the character is discarded and Stage 2 terminates. If it is not discarded, then a check is made to determine if `c` is allowed as the next character of an input field of the conversion specifier returned by Stage 1. If so, it is accumulated.

If the character is either discarded or accumulated then `in` is advanced by `++in` and processing returns to the beginning of stage 2.

Stage 3: The sequence of `char`s accumulated in stage 2 (the field) is converted to a numeric value by the rules of one of the functions declared in the header `<cstdlib>`:

— For a signed integer value, the function `strtoll`.

— For an unsigned integer value, the function `strtoull`.

— For a floating-point value, the function `strtold`.

The numeric value to be stored can be one of:

— zero, if the conversion function fails to convert the entire field. `ios_base::failbit` is assigned to `err`.

— the most positive representable value, if the field represents a value too large positive to be represented in `val`. `ios_base::failbit` is assigned to `err`.

— the most negative representable value or zero for an unsigned integer type, if the field represents a value too large negative to be represented in `val`. `ios_base::failbit` is assigned to `err`.

— the converted value, otherwise.

The resultant numeric value is stored in `val`.

1 Digit grouping is checked. That is, the positions of discarded separators is examined for consistency with `use_facet<numpunct<charT> >(loc).grouping()`. If they are not consistent then `ios_base::failbit` is assigned to `err`.

2 In any case, if stage 2 processing was terminated by the test for `in==end` then `err |=ios_base::eofbit` is performed.

```
iter_type do_get(iter_type in, iter_type end, ios_base& str,
                 ios_base::iostate& err, bool& val) const;
```

3

Effects: If `(str.flags()&ios_base::boolalpha)==0` then input proceeds as it would for a `long` except that if a value is being stored into `val`, the value is determined according to the following: If the value to be stored is 0 then `false` is stored. If the value is 1 then `true` is stored. Otherwise `true` is stored and `ios_base::failbit` is assigned to `err`.

1

Otherwise target sequences are determined "as if" by calling the members `falsename()` and `truename()` of the facet obtained by `use_facet<numpunct<charT> >(str.getloc())`. Successive characters in the range `[in,end)` (see 23.224.1) are obtained and matched against corresponding positions in the target sequences only as necessary to identify a unique match. The input iterator `in` is compared to `end` only when necessary to obtain a character. If a target sequence is uniquely matched, `val` is set to the corresponding value. Otherwise `false` is stored and `ios_base::failbit` is assigned to `err`.

1

The `in` iterator is always left pointing one position beyond the last character successfully matched. If `val` is set, then `err` is set to `str.goodbit`; or to `str.eofbit` if, when seeking another character to match, it is found that `(in == end)`. If `val` is not set, then `err` is set to `str.failbit`; or to `(str.failbit|str.eofbit)` if the reason for the failure was that `(in == end)`. [*Example:* For targets `true`: `"a"` and `false`: `"abb"`, the input sequence `"a"` yields `val == true` and `err == str.eofbit`; the input sequence `"abc"` yields `err = str.failbit`, with `in` ending at the `'c'` element. For targets `true`: `"1"` and `false`: `"0"`, the input sequence `"1"` yields `val == true` and `err == str.goodbit`. For empty targets `("")`, any input sequence yields `err == str.failbit`. — *end example*]

1 *Returns:* `in`.

22.90.0.1 Class template `num_put` [locale.nm.put]

```
namespace std {
  template <class charT, class OutputIterator = ostreambuf_iterator<charT> >
  class num_put : public locale::facet {
  public:
    typedef charT            char_type;
    typedef OutputIterator   iter_type;

    explicit num_put(size_t refs = 0);

    iter_type put(iter_type s, ios_base& f, char_type fill, bool v) const;
    iter_type put(iter_type s, ios_base& f, char_type fill, long v) const;
    iter_type put(iter_type s, ios_base& f, char_type fill, long long v) const;
    iter_type put(iter_type s, ios_base& f, char_type fill,
                  unsigned long v) const;
    iter_type put(iter_type s, ios_base& f, char_type fill,
                  unsigned long long v) const;
    iter_type put(iter_type s, ios_base& f, char_type fill,
                  double v) const;
    iter_type put(iter_type s, ios_base& f, char_type fill,
                  long double v) const;
    iter_type put(iter_type s, ios_base& f, char_type fill,
                  const void* v) const;

    static locale::id id;

  protected:
    ~num_put();
```

```
    virtual iter_type do_put(iter_type, ios_base&, char_type fill,
                             bool v) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill,
                             long v) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill,
                             long long v) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill,
                             unsigned long) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill,
                             unsigned long long) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill,
                             double v) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill,
                             long double v) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill,
                             const void* v) const;
  };
}
```

1 The facet `num_put` is used to format numeric values to a character sequence such as an ostream.

22.90.0.1.1 `num_put` members [facet.num.put.members]

```
iter_type put(iter_type out, ios_base& str, char_type fill,
  bool val) const;
iter_type put(iter_type out, ios_base& str, char_type fill,
  long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill,
  long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill,
  unsigned long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill,
  unsigned long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill,
  double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill,
  long double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill,
  const void* val) const;
```

1 *Returns:* `do_put(out, str, fill, val)`.

22.90.0.1.2 `num_put` virtual functions [facet.num.put.virtuals]

```
iter_type do_put(iter_type out, ios_base& str, char_type fill,
  long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill,
  long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill,
  unsigned long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill,
  unsigned long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill,
  double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill,
  long double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill,
```

```
const void* val) const;
```

1 *Effects:* Writes characters to the sequence `out`, formatting `val` as desired. In the following description, a local variable initialized with

```
locale loc = str.getloc();
```

2 The details of this operation occur in several stages:

(2.1) — Stage 1: Determine a printf conversion specifier `spec` and determining the characters that would be printed by `printf` (27.310.1) given this conversion specifier for

```
printf(spec, val )
```

assuming that the current locale is the `"C"` locale.

(2.2) — Stage 2: Adjust the representation by converting each `char` determined by stage 1 to a `charT` using a conversion and values returned by members of `use_facet< numpunct<charT> >(str.getloc())`

(2.3) — Stage 3: Determine where padding is required.

(2.4) — Stage 4: Insert the sequence into the `out`.

3 Detailed descriptions of each stage follow.

4 *Returns:* `out`.

5

Stage 1: The first action of stage 1 is to determine a conversion specifier. The tables that describe this determination use the following local variables

```
fmtflags flags = str.flags() ;
fmtflags basefield =  (flags & (ios_base::basefield));
fmtflags uppercase =  (flags & (ios_base::uppercase));
fmtflags floatfield = (flags & (ios_base::floatfield));
fmtflags showpos =    (flags & (ios_base::showpos));
fmtflags showbase =   (flags & (ios_base::showbase));
```

All tables used in describing stage 1 are ordered. That is, the first line whose condition is true applies. A line without a condition is the default behavior when none of the earlier lines apply.

For conversion from an integral type other than a character type, the function determines the integral conversion specifier as indicated in Table 87.

Table 87 — Integer conversions

State	`stdio` equivalent
`basefield == ios_base::oct`	`%o`
`(basefield == ios_base::hex) && !uppercase`	`%x`
`(basefield == ios_base::hex)`	`%X`
for a `signed` integral type	`%d`
for an `unsigned` integral type	`%u`

For conversion from a floating-point type, the function determines the floating-point conversion specifier as indicated in Table 88.

For conversions from an integral or floating-point type a length modifier is added to the conversion specifier as indicated in Table 89.

The conversion specifier has the following optional additional qualifiers prepended as indicated in Table 90.

Table 88 — Floating-point conversions

State	stdio equivalent
`floatfield == ios_base::fixed`	`%f`
`floatfield == ios_base::scientific && !uppercase`	`%e`
`floatfield == ios_base::scientific`	`%E`
`floatfield == (ios_base::fixed | ios_base::scientific) && !uppercase`	`%a`
`floatfield == (ios_base::fixed | ios_base::scientific)`	`%A`
`!uppercase`	`%g`
otherwise	`%G`

Table 89 — Length modifier

Type	Length modifier
`long`	`l`
`long long`	`ll`
`unsigned long`	`l`
`unsigned long long`	`ll`
`long double`	`L`
otherwise	*none*

Table 90 — Numeric conversions

Type(s)	State	stdio equivalent
an integral type	`flags & showpos`	`+`
	`flags & showbase`	`#`
a floating-point type	`flags & showpos`	`+`
	`flags & showpoint`	`#`

For conversion from a floating-point type, if `floatfield != (ios_base::fixed | ios_base::scientific)`, `str.precision()` is specified as precision in the conversion specification. Otherwise, no precision is specified.

For conversion from `void*` the specifier is `%p`.

The representations at the end of stage 1 consists of the `char`'s that would be printed by a call of `printf(s, val)` where `s` is the conversion specifier determined above.

Stage 2: Any character `c` other than a decimal point(.) is converted to a `charT` via `use_facet<ctype<charT> >(loc).widen( c )`

A local variable `punct` is initialized via

```
const numpunct<charT>& punct = use_facet< numpunct<charT> >(str.getloc());
```

For arithmetic types, `punct.thousands_sep()` characters are inserted into the sequence as determined by the value returned by `punct.do_grouping()` using the method described in 22.102.1.1.2

Decimal point characters(.) are replaced by `punct.decimal_point()`

Stage 3: A local variable is initialized as

```
fmtflags adjustfield=   (flags & (ios_base::adjustfield));
```

The location of any padding[246] is determined according to Table 91.

246) The conversion specification `#o` generates a leading `0` which is *not* a padding character.

Table 91 — Fill padding

State	Location
`adjustfield == ios_base::left`	pad after
`adjustfield == ios_base::right`	pad before
`adjustfield == internal` and a sign occurs in the representation	pad after the sign
`adjustfield == internal` and representation after stage 1 began with 0x or 0X	pad after x or X
otherwise	pad before

If `str.width()` is nonzero and the number of `charT`'s in the sequence after stage 2 is less than `str.width()`, then enough `fill` characters are added to the sequence at the position indicated for padding to bring the length of the sequence to `str.width()`.

`str.width(0)` is called.

Stage 4: The sequence of `charT`'s at the end of stage 3 are output via

```
*out++ = c
```

```
iter_type do_put(iter_type out, ios_base& str, char_type fill,
                 bool val) const;
```

1 *Returns:* If `(str.flags() & ios_base::boolalpha) == 0` returns `do_put(out, str, fill, (int)val)`, otherwise obtains a string `s` as if by

```
string_type s =
  val ? use_facet<numpunct<charT>>(loc).truename()
    : use_facet<numpunct<charT>>(loc).falsename();
```

and then inserts each character `c` of `s` into `out` via `*out++ = c` and returns `out`.

22.102.1 The numeric punctuation facet [facet.numpunct]

22.102.1.1 Class template `numpunct` [locale.numpunct]

```
namespace std {
  template <class charT>
  class numpunct : public locale::facet {
  public:
    typedef charT               char_type;
    typedef basic_string<charT> string_type;

    explicit numpunct(size_t refs = 0);

    char_type    decimal_point()   const;
    char_type    thousands_sep()   const;
    string       grouping()        const;
    string_type  truename()        const;
    string_type  falsename()       const;

    static locale::id id;

  protected:
   ~numpunct();                  // virtual
    virtual char_type    do_decimal_point() const;
```

```
    virtual char_type    do_thousands_sep() const;
    virtual string       do_grouping()      const;
    virtual string_type  do_truename()      const;      // for bool
    virtual string_type  do_falsename()     const;      // for bool
  };
}
```

1 `numpunct<>` specifies numeric punctuation. The specializations required in Table 81 (22.6.0.1.1), namely `numpunct<wchar_t>` and `numpunct<char>`, provide classic `"C"` numeric formats, i.e., they contain information equivalent to that contained in the `"C"` locale or their wide character counterparts as if obtained by a call to `widen`.

2 The syntax for number formats is as follows, where `digit` represents the radix set specified by the `fmtflags` argument value, and `thousands-sep` and `decimal-point` are the results of corresponding `numpunct<charT>` members. Integer values have the format:

```
integer   ::= [sign] units
sign      ::= plusminus
plusminus ::= '+' | '-'
units     ::= digits [thousands-sep units]
digits    ::= digit [digits]
```

and floating-point values have:

```
floatval ::= [sign] units [decimal-point [digits]] [e [sign] digits] |
             [sign]       decimal-point  digits   [e [sign] digits]
e        ::= 'e' | 'E'
```

where the number of digits between `thousands-sep`s is as specified by `do_grouping()`. For parsing, if the `digits` portion contains no thousands-separators, no grouping constraint is applied.

22.102.1.1.1 `numpunct` members [facet.numpunct.members]

`char_type decimal_point() const;`

1 *Returns:* `do_decimal_point()`

`char_type thousands_sep() const;`

2 *Returns:* `do_thousands_sep()`

`string grouping()  const;`

3 *Returns:* `do_grouping()`

```
string_type truename()  const;
string_type falsename() const;
```

4 *Returns:* `do_truename()` or `do_falsename()`, respectively.

22.102.1.1.2 `numpunct` virtual functions [facet.numpunct.virtuals]

`char_type do_decimal_point() const;`

1 *Returns:* A character for use as the decimal radix separator. The required specializations return `'.'` or `L'.'`.

`char_type do_thousands_sep() const;`

2 *Returns:* A character for use as the digit group separator. The required specializations return `','` or `L','`.

```
string do_grouping() const;
```

3 *Returns:* A basic_string<char> `vec` used as a vector of integer values, in which each element `vec[i]` represents the number of digits[247] in the group at position `i`, starting with position 0 as the rightmost group. If `vec.size() <= i`, the number is the same as group `(i-1)`; if `(i<0 || vec[i]<=0 || vec[i]==CHAR_MAX)`, the size of the digit group is unlimited.

4 The required specializations return the empty string, indicating no grouping.

```
string_type do_truename()  const;
string_type do_falsename() const;
```

5 *Returns:* A string representing the name of the boolean value `true` or `false`, respectively.

6 In the base class implementation these names are `"true"` and `"false"`, or `L"true"` and `L"false"`.

22.102.1.2 Class template `numpunct_byname` [locale.numpunct.byname]

```
namespace std {
  template <class charT>
  class numpunct_byname : public numpunct<charT> {
  // this class is specialized for char and wchar_t.
  public:
    typedef charT                char_type;
    typedef basic_string<charT>  string_type;
    explicit numpunct_byname(const char*, size_t refs = 0);
    explicit numpunct_byname(const string&, size_t refs = 0);
  protected:
   ~numpunct_byname();
  };
}
```

22.102.2 The collate category [category.collate]

22.102.2.1 Class template `collate` [locale.collate]

```
namespace std {
  template <class charT>
  class collate : public locale::facet {
  public:
    typedef charT               char_type;
    typedef basic_string<charT> string_type;

    explicit collate(size_t refs = 0);

    int compare(const charT* low1, const charT* high1,
                const charT* low2, const charT* high2) const;
    string_type transform(const charT* low, const charT* high) const;
    long hash(const charT* low, const charT* high) const;

    static locale::id id;

  protected:
    ~collate();
    virtual int do_compare(const charT* low1, const charT* high1,
                           const charT* low2, const charT* high2) const;
```

247) Thus, the string `"\003"` specifies groups of 3 digits each, and `"3"` probably indicates groups of 51 (!) digits each, because 51 is the ASCII value of `"3"`.

```
    virtual string_type do_transform(const charT* low, const charT* high) const;
    virtual long do_hash (const charT* low, const charT* high) const;
  };
}
```

1 The class `collate<charT>` provides features for use in the collation (comparison) and hashing of strings. A locale member function template, `operator()`, uses the collate facet to allow a locale to act directly as the predicate argument for standard algorithms (Clause 25) and containers operating on strings. The specializations required in Table 81 (22.6.0.1.1), namely `collate<char>` and `collate<wchar_t>`, apply lexicographic ordering (25.204.1).

2 Each function compares a string of characters `*p` in the range `[low,high)`.

22.102.2.1.1 `collate` members [locale.collate.members]

```
int compare(const charT* low1, const charT* high1,
            const charT* low2, const charT* high2) const;
```

1 *Returns:* `do_compare(low1, high1, low2, high2)`

```
string_type transform(const charT* low, const charT* high) const;
```

2 *Returns:* `do_transform(low, high)`

```
long hash(const charT* low, const charT* high) const;
```

3 *Returns:* `do_hash(low, high)`

22.102.2.1.2 `collate` virtual functions [locale.collate.virtuals]

```
int do_compare(const charT* low1, const charT* high1,
               const charT* low2, const charT* high2) const;
```

1 *Returns:* `1` if the first string is greater than the second, `-1` if less, zero otherwise. The specializations required in Table 81 (22.6.0.1.1), namely `collate<char>` and `collate<wchar_t>`, implement a lexicographical comparison (25.204.1).

```
string_type do_transform(const charT* low, const charT* high) const;
```

2 *Returns:* A `basic_string<charT>` value that, compared lexicographically with the result of calling `transform()` on another string, yields the same result as calling `do_compare()` on the same two strings.[248]

```
long do_hash(const charT* low, const charT* high) const;
```

3 *Returns:* An integer value equal to the result of calling `hash()` on any other string for which `do_compare()` returns 0 (equal) when passed the two strings. [*Note:* The probability that the result equals that for another string which does not compare equal should be very small, approaching `(1.0/numeric_limits<unsigned long>::max())`. — *end note*]

22.102.2.2 Class template `collate_byname` [locale.collate.byname]

```
namespace std {
  template <class charT>
  class collate_byname : public collate<charT> {
  public:
    typedef basic_string<charT> string_type;
    explicit collate_byname(const char*, size_t refs = 0);
```

248) This function is useful when one string is being compared to many other strings.

```
    explicit collate_byname(const string&, size_t refs = 0);
  protected:
    ~collate_byname();
  };
}
```

22.102.3 The time category [category.time]

1 Templates `time_get<charT,InputIterator>` and `time_put<charT,OutputIterator>` provide date and time formatting and parsing. All specifications of member functions for `time_put` and `time_get` in the subclauses of 22.102.3 only apply to the specializations required in Tables 81 and 82 (22.6.0.1.1). Their members use their `ios_base&`, `ios_base::iostate&`, and `fill` arguments as described in (22.31), and the `ctype<>` facet, to determine formatting details.

22.102.3.1 Class template `time_get` [locale.time.get]

```
namespace std {
  class time_base {
  public:
    enum dateorder { no_order, dmy, mdy, ymd, ydm };
  };

  template <class charT, class InputIterator = istreambuf_iterator<charT> >
  class time_get : public locale::facet, public time_base {
  public:
    typedef charT            char_type;
    typedef InputIterator    iter_type;

    explicit time_get(size_t refs = 0);

    dateorder date_order()  const { return do_date_order(); }
    iter_type get_time(iter_type s, iter_type end, ios_base& f,
                       ios_base::iostate& err, tm* t)  const;
    iter_type get_date(iter_type s, iter_type end, ios_base& f,
                       ios_base::iostate& err, tm* t)  const;
    iter_type get_weekday(iter_type s, iter_type end, ios_base& f,
                       ios_base::iostate& err, tm* t) const;
    iter_type get_monthname(iter_type s, iter_type end, ios_base& f,
                       ios_base::iostate& err, tm* t) const;
    iter_type get_year(iter_type s, iter_type end, ios_base& f,
                       ios_base::iostate& err, tm* t) const;
    iter_type get(iter_type s, iter_type end, ios_base& f,
                       ios_base::iostate& err, tm* t, char format, char modifier = 0) const;
    iter_type get(iter_type s, iter_type end, ios_base& f,
                       ios_base::iostate& err, tm* t, const char_type* fmt,
                       const char_type* fmtend) const;

    static locale::id id;

  protected:
    ~time_get();
    virtual dateorder do_date_order()  const;
    virtual iter_type do_get_time(iter_type s, iter_type end, ios_base&,
                                  ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_date(iter_type s, iter_type end, ios_base&,
                                  ios_base::iostate& err, tm* t) const;
```

```
    virtual iter_type do_get_weekday(iter_type s, iter_type end, ios_base&,
                                     ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_monthname(iter_type s, iter_type end, ios_base&,
                                       ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_year(iter_type s, iter_type end, ios_base&,
                                  ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get(iter_type s, iter_type end, ios_base& f,
                             ios_base::iostate& err, tm* t, char format, char modifier) const;
  };
}
```

1 `time_get` is used to parse a character sequence, extracting components of a time or date into a `struct tm` record. Each `get` member parses a format as produced by a corresponding format specifier to `time_put<>::put`. If the sequence being parsed matches the correct format, the corresponding members of the `struct tm` argument are set to the values used to produce the sequence; otherwise either an error is reported or unspecified values are assigned.[249]

2 If the end iterator is reached during parsing by any of the `get()` member functions, the member sets `ios_base::eofbit` in `err`.

22.102.3.1.1 `time_get` members [locale.time.get.members]

```
dateorder date_order() const;
```

1 *Returns:* `do_date_order()`

```
iter_type get_time(iter_type s, iter_type end, ios_base& str,
                   ios_base::iostate& err, tm* t) const;
```

2 *Returns:* `do_get_time(s, end, str, err, t)`

```
iter_type get_date(iter_type s, iter_type end, ios_base& str,
                   ios_base::iostate& err, tm* t) const;
```

3 *Returns:* `do_get_date(s, end, str, err, t)`

```
iter_type get_weekday(iter_type s, iter_type end, ios_base& str,
                      ios_base::iostate& err, tm* t) const;
iter_type get_monthname(iter_type s, iter_type end, ios_base& str,
                        ios_base::iostate& err, tm* t) const;
```

4 *Returns:* `do_get_weekday(s, end, str, err, t)` or `do_get_monthname(s, end, str, err, t)`

```
iter_type get_year(iter_type s, iter_type end, ios_base& str,
                   ios_base::iostate& err, tm* t) const;
```

5 *Returns:* `do_get_year(s, end, str, err, t)`

```
iter_type get(iter_type s, iter_type end, ios_base& f,
    ios_base::iostate& err, tm* t, char format, char modifier = 0) const;
```

6 *Returns:* `do_get(s, end, f, err, t, format, modifier)`

```
iter_type get(iter_type s, iter_type end, ios_base& f,
    ios_base::iostate& err, tm* t, const char_type* fmt, const char_type* fmtend) const;
```

249) In other words, user confirmation is required for reliable parsing of user-entered dates and times, but machine-generated formats can be parsed reliably. This allows parsers to be aggressive about interpreting user variations on standard formats.

7 *Requires:* `[fmt,fmtend)` shall be a valid range.

8 *Effects:* The function starts by evaluating `err = ios_base::goodbit`. It then enters a loop, reading zero or more characters from `s` at each iteration. Unless otherwise specified below, the loop terminates when the first of the following conditions holds:

— The expression `fmt == fmtend` evaluates to true.

— The expression `err == ios_base::goodbit` evaluates to false.

— The expression `s == end` evaluates to true, in which case the function evaluates `err = ios_base::eofbit | ios_base::failbit`.

— The next element of `fmt` is equal to `'%'`, optionally followed by a modifier character, followed by a conversion specifier character, `format`, together forming a conversion specification valid for the ISO/IEC 9945 function `strptime`. If the number of elements in the range `[fmt,fmtend)` is not sufficient to unambiguously determine whether the conversion specification is complete and valid, the function evaluates `err = ios_base::failbit`. Otherwise, the function evaluates `s = do_get(s, end, f, err, t, format, modifier)`, where the value of `modifier` is `'\0'` when the optional modifier is absent from the conversion specification. If `err == ios_base::goodbit` holds after the evaluation of the expression, the function increments `fmt` to point just past the end of the conversion specification and continues looping.

— The expression `isspace(*fmt, f.getloc())` evaluates to true, in which case the function first increments `fmt` until `fmt == fmtend || !isspace(*fmt, f.getloc())` evaluates to true, then advances `s` until `s == end || !isspace(*s, f.getloc())` is true, and finally resumes looping.

— The next character read from `s` matches the element pointed to by `fmt` in a case-insensitive comparison, in which case the function evaluates `++fmt, ++s` and continues looping. Otherwise, the function evaluates `err = ios_base::failbit`.

1 [*Note:* The function uses the `ctype<charT>` facet installed in `f`'s locale to determine valid whitespace characters. It is unspecified by what means the function performs case-insensitive comparison or whether multi-character sequences are considered while doing so. — *end note*]

2 *Returns:* `s`

22.105.0.0.1 `time_get` virtual functions [locale.time.get.virtuals]

```
dateorder do_date_order() const;
```

1 *Returns:* An enumeration value indicating the preferred order of components for those date formats that are composed of day, month, and year.[250] Returns `no_order` if the date format specified by `'x'` contains other variable components (e.g., Julian day, week number, week day).

```
iter_type do_get_time(iter_type s, iter_type end, ios_base& str,
                      ios_base::iostate& err, tm* t) const;
```

2 *Effects:* Reads characters starting at `s` until it has extracted those `struct tm` members, and remaining format characters, used by `time_put<>::put` to produce the format specified by `"%H:%M:%S"`, or until it encounters an error or end of sequence.

3 *Returns:* An iterator pointing immediately beyond the last character recognized as possibly part of a valid time.

```
iter_type do_get_date(iter_type s, iter_type end, ios_base& str,
                      ios_base::iostate& err, tm* t) const;
```

250) This function is intended as a convenience only, for common formats, and may return `no_order` in valid locales.

4 *Effects:* Reads characters starting at `s` until it has extracted those `struct tm` members and remaining format characters used by `time_put<>::put` to produce one of the following formats, or until it encounters an error. The format depends on the value returned by `date_order()` as shown in Table 92.

Table 92 — `do_get_date` effects

date_order()	Format
no_order	"%m%d%y"
dmy	"%d%m%y"
mdy	"%m%d%y"
ymd	"%y%m%d"
ydm	"%y%d%m"

5 An implementation may also accept additional implementation-defined formats.

6 *Returns:* An iterator pointing immediately beyond the last character recognized as possibly part of a valid date.

```
iter_type do_get_weekday(iter_type s, iter_type end, ios_base& str,
                         ios_base::iostate& err, tm* t) const;
iter_type do_get_monthname(iter_type s, iter_type end, ios_base& str,
                           ios_base::iostate& err, tm* t) const;
```

7 *Effects:* Reads characters starting at `s` until it has extracted the (perhaps abbreviated) name of a weekday or month. If it finds an abbreviation that is followed by characters that could match a full name, it continues reading until it matches the full name or fails. It sets the appropriate `struct tm` member accordingly.

8 *Returns:* An iterator pointing immediately beyond the last character recognized as part of a valid name.

```
iter_type do_get_year(iter_type s, iter_type end, ios_base& str,
                      ios_base::iostate& err, tm* t) const;
```

9 *Effects:* Reads characters starting at `s` until it has extracted an unambiguous year identifier. It is implementation-defined whether two-digit year numbers are accepted, and (if so) what century they are assumed to lie in. Sets the `t->tm_year` member accordingly.

10 *Returns:* An iterator pointing immediately beyond the last character recognized as part of a valid year identifier.

```
iter_type do_get(iter_type s, iter_type end, ios_base& f,
    ios_base::iostate& err, tm* t, char format, char modifier) const;
```

11 *Requires:* `t` shall point to an object.

12 *Effects:* The function starts by evaluating `err = ios_base::goodbit`. It then reads characters starting at `s` until it encounters an error, or until it has extracted and assigned those `struct tm` members, and any remaining format characters, corresponding to a conversion directive appropriate for the ISO/IEC 9945 function `strptime`, formed by concatenating `'%'`, the `modifier` character, when non-NUL, and the `format` character. When the concatenation fails to yield a complete valid directive the function leaves the object pointed to by `t` unchanged and evaluates `err |= ios_base::failbit`. When `s == end` evaluates to true after reading a character the function evaluates `err |= ios_base::eofbit`.

13 For complex conversion directives such as `%c`, `%x`, or `%X`, or directives that involve the optional modifiers `E` or `O`, when the function is unable to unambiguously determine some or all `struct tm` members from

the input sequence `[s,end)`, it evaluates `err |= ios_base::eofbit`. In such cases the values of those `struct tm` members are unspecified and may be outside their valid range.

14 *Remark:* It is unspecified whether multiple calls to `do_get()` with the address of the same `struct tm` object will update the current contents of the object or simply overwrite its members. Portable programs must zero out the object before invoking the function.

15 *Returns:* An iterator pointing immediately beyond the last character recognized as possibly part of a valid input sequence for the given `format` and `modifier`.

22.105.0.1 Class template `time_get_byname` [locale.time.get.byname]

```
namespace std {
  template <class charT, class InputIterator = istreambuf_iterator<charT> >
  class time_get_byname : public time_get<charT, InputIterator> {
  public:
    typedef time_base::dateorder dateorder;
    typedef InputIterator        iter_type;

    explicit time_get_byname(const char*, size_t refs = 0);
    explicit time_get_byname(const string&, size_t refs = 0);
  protected:
    ~time_get_byname();
  };
}
```

22.105.0.2 Class template `time_put` [locale.time.put]

```
namespace std {
  template <class charT, class OutputIterator = ostreambuf_iterator<charT> >
  class time_put : public locale::facet {
  public:
    typedef charT            char_type;
    typedef OutputIterator   iter_type;

    explicit time_put(size_t refs = 0);

    // the following is implemented in terms of other member functions.
    iter_type put(iter_type s, ios_base& f, char_type fill, const tm* tmb,
                  const charT* pattern, const charT* pat_end) const;
    iter_type put(iter_type s, ios_base& f, char_type fill,
                  const tm* tmb, char format, char modifier = 0) const;

    static locale::id id;

  protected:
    ~time_put();
    virtual iter_type do_put(iter_type s, ios_base&, char_type, const tm* t,
                             char format, char modifier) const;
  };
}
```

22.105.0.2.1 `time_put` members [locale.time.put.members]

```
iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
              const charT* pattern, const charT* pat_end) const;
iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
              char format, char modifier = 0) const;
```

1 *Effects:* The first form steps through the sequence from `pattern` to `pat_end`, identifying characters that are part of a format sequence. Each character that is not part of a format sequence is written to `s` immediately, and each format sequence, as it is identified, results in a call to `do_put`; thus, format elements and other characters are interleaved in the output in the order in which they appear in the pattern. Format sequences are identified by converting each character `c` to a `char` value as if by `ct.narrow(c,0)`, where `ct` is a reference to `ctype<charT>` obtained from `str.getloc()`. The first character of each sequence is equal to `'%'`, followed by an optional modifier character `mod`[251] and a format specifier character `spec` as defined for the function `strftime`. If no modifier character is present, `mod` is zero. For each valid format sequence identified, calls `do_put(s, str, fill, t, spec, mod)`.

2 The second form calls `do_put(s, str, fill, t, format, modifier)`.

3 [*Note:* The `fill` argument may be used in the implementation-defined formats or by derivations. A space character is a reasonable default for this argument. — *end note*]

4 *Returns:* An iterator pointing immediately after the last character produced.

22.105.0.2.2 `time_put` virtual functions [locale.time.put.virtuals]

```
iter_type do_put(iter_type s, ios_base&, char_type fill, const tm* t,
                 char format, char modifier) const;
```

1 *Effects:* Formats the contents of the parameter `t` into characters placed on the output sequence `s`. Formatting is controlled by the parameters `format` and `modifier`, interpreted identically as the format specifiers in the string argument to the standard library function `strftime()`[252], except that the sequence of characters produced for those specifiers that are described as depending on the C locale are instead implementation-defined.[253]

2 *Returns:* An iterator pointing immediately after the last character produced. [*Note:* The `fill` argument may be used in the implementation-defined formats or by derivations. A space character is a reasonable default for this argument. — *end note*]

22.105.0.3 Class template `time_put_byname` [locale.time.put.byname]

```
namespace std {
  template <class charT, class OutputIterator = ostreambuf_iterator<charT> >
  class time_put_byname : public time_put<charT, OutputIterator>
  {
  public:
    typedef charT          char_type;
    typedef OutputIterator iter_type;

    explicit time_put_byname(const char*, size_t refs = 0);
    explicit time_put_byname(const string&, size_t refs = 0);
  protected:
    ~time_put_byname();
  };
}
```

22.105.1 The monetary category [category.monetary]

1 These templates handle monetary formats. A template parameter indicates whether local or international monetary formats are to be used.

251) Although the C programming language defines no modifiers, most vendors do.
252) Interpretation of the `modifier` argument is implementation-defined, but should follow POSIX conventions.
253) Implementations are encouraged to refer to other standards such as POSIX for these definitions.

2 All specifications of member functions for money_put and money_get in the subclauses of 22.105.1 only apply to the specializations required in Tables 81 and 82 (22.6.0.1.1). Their members use their ios_base&, ios_base::iostate&, and fill arguments as described in (22.31), and the moneypunct<> and ctype<> facets, to determine formatting details.

22.105.1.1 Class template money_get [locale.money.get]

```
namespace std {
  template <class charT,
    class InputIterator = istreambuf_iterator<charT> >
  class money_get : public locale::facet {
  public:
    typedef charT               char_type;
    typedef InputIterator       iter_type;
    typedef basic_string<charT> string_type;

    explicit money_get(size_t refs = 0);

    iter_type get(iter_type s, iter_type end, bool intl,
                  ios_base& f, ios_base::iostate& err,
                  long double& units) const;
    iter_type get(iter_type s, iter_type end, bool intl,
                  ios_base& f, ios_base::iostate& err,
                  string_type& digits) const;

    static locale::id id;

  protected:
    ~money_get();
    virtual iter_type do_get(iter_type, iter_type, bool, ios_base&,
                             ios_base::iostate& err, long double& units) const;
    virtual iter_type do_get(iter_type, iter_type, bool, ios_base&,
                             ios_base::iostate& err, string_type& digits) const;
  };
}
```

22.105.1.1.1 money_get members [locale.money.get.members]

```
iter_type get(iter_type s, iter_type end, bool intl,
              ios_base& f, ios_base::iostate& err,
              long double& quant) const;
iter_type get(s, iter_type end, bool intl, ios_base&f,
              ios_base::iostate& err, string_type& quant) const;
```

1 *Returns:* do_get(s, end, intl, f, err, quant)

22.105.1.1.2 money_get virtual functions [locale.money.get.virtuals]

```
iter_type do_get(iter_type s, iter_type end, bool intl,
                 ios_base& str, ios_base::iostate& err,
                 long double& units) const;
iter_type do_get(iter_type s, iter_type end, bool intl,
                 ios_base& str, ios_base::iostate& err,
                 string_type& digits) const;
```

1 *Effects:* Reads characters from s to parse and construct a monetary value according to the format specified by a moneypunct<charT,Intl> facet reference mp and the character mapping specified by a ctype<charT> facet reference ct obtained from the locale returned by str.getloc(),

and `str.flags()`. If a valid sequence is recognized, does not change `err`; otherwise, sets `err` to `(err|str.failbit)`, or `(err|str.failbit|str.eofbit)` if no more characters are available, and does not change `units` or `digits`. Uses the pattern returned by `mp.neg_format()` to parse all values. The result is returned as an integral value stored in `units` or as a sequence of digits possibly preceded by a minus sign (as produced by `ct.widen(c)` where `c` is `'-'` or in the range from `'0'` through `'9'`, inclusive) stored in `digits`. [*Example:* The sequence `$1,056.23` in a common United States locale would yield, for `units`, `105623`, or, for `digits`, `"105623"`. — *end example*] If `mp.grouping()` indicates that no thousands separators are permitted, any such characters are not read, and parsing is terminated at the point where they first appear. Otherwise, thousands separators are optional; if present, they are checked for correct placement only after all format components have been read.

2 Where `money_base::space` or `money_base::none` appears as the last element in the format pattern, no white space is consumed. Otherwise, where `money_base::space` appears in any of the initial elements of the format pattern, at least one white space character is required. Where `money_base::none` appears in any of the initial elements of the format pattern, white space is allowed but not required. If `(str.flags() & str.showbase)` is false, the currency symbol is optional and is consumed only if other characters are needed to complete the format; otherwise, the currency symbol is required.

3 If the first character (if any) in the string `pos` returned by `mp.positive_sign()` or the string `neg` returned by `mp.negative_sign()` is recognized in the position indicated by `sign` in the format pattern, it is consumed and any remaining characters in the string are required after all the other format components. [*Example:* If `showbase` is off, then for a `neg` value of `"()"` and a currency symbol of `"L"`, in `"(100 L)"` the `"L"` is consumed; but if `neg` is `"-"`, the `"L"` in `"-100 L"` is not consumed. — *end example*] If `pos` or `neg` is empty, the sign component is optional, and if no sign is detected, the result is given the sign that corresponds to the source of the empty string. Otherwise, the character in the indicated position must match the first character of `pos` or `neg`, and the result is given the corresponding sign. If the first character of `pos` is equal to the first character of `neg`, or if both strings are empty, the result is given a positive sign.

4 Digits in the numeric monetary component are extracted and placed in `digits`, or into a character buffer `buf1` for conversion to produce a value for `units`, in the order in which they appear, preceded by a minus sign if and only if the result is negative. The value `units` is produced as if by[254]

```
for (int i = 0; i < n; ++i)
  buf2[i] = src[find(atoms, atoms+sizeof(src), buf1[i]) - atoms];
buf2[n] = 0;
sscanf(buf2, "%Lf", &units);
```

where `n` is the number of characters placed in `buf1`, `buf2` is a character buffer, and the values `src` and `atoms` are defined as if by

```
static const char src[] = "0123456789-";
charT atoms[sizeof(src)];
ct.widen(src, src + sizeof(src) - 1, atoms);
```

5 *Returns:* An iterator pointing immediately beyond the last character recognized as part of a valid monetary quantity.

22.105.1.2 Class template `money_put` [locale.money.put]

```
namespace std {
  template <class charT,
    class OutputIterator = ostreambuf_iterator<charT> >
  class money_put : public locale::facet {
```

254) The semantics here are different from `ct.narrow`.

```
  public:
    typedef charT               char_type;
    typedef OutputIterator      iter_type;
    typedef basic_string<charT> string_type;

    explicit money_put(size_t refs = 0);

    iter_type put(iter_type s, bool intl, ios_base& f,
                  char_type fill, long double units) const;
    iter_type put(iter_type s, bool intl, ios_base& f,
                  char_type fill, const string_type& digits) const;

    static locale::id id;

  protected:
    ~money_put();
    virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill,
                             long double units) const;
    virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill,
                             const string_type& digits) const;
  };
}
```

22.105.1.2.1 money_put members [locale.money.put.members]

```
iter_type put(iter_type s, bool intl, ios_base& f, char_type fill,
              long double quant) const;
iter_type put(iter_type s, bool intl, ios_base& f, char_type fill,
              const string_type& quant) const;
```

1 *Returns:* `do_put(s, intl, f, loc, quant)`

22.105.1.2.2 money_put virtual functions [locale.money.put.virtuals]

```
iter_type do_put(iter_type s, bool intl, ios_base& str,
                 char_type fill, long double units) const;
iter_type do_put(iter_type s, bool intl, ios_base& str,
                 char_type fill, const string_type& digits) const;
```

1

Effects: Writes characters to `s` according to the format specified by a `moneypunct<charT,Intl>` facet reference `mp` and the character mapping specified by a `ctype<charT>` facet reference `ct` obtained from the locale returned by `str.getloc()`, and `str.flags()`. The argument `units` is transformed into a sequence of wide characters as if by

```
ct.widen(buf1, buf1 + sprintf(buf1, "%.0Lf", units), buf2)
```

for character buffers `buf1` and `buf2`. If the first character in `digits` or `buf2` is equal to `ct.widen('-')`, then the pattern used for formatting is the result of `mp.neg_format()`; otherwise the pattern is the result of `mp.pos_format()`. Digit characters are written, interspersed with any thousands separators and decimal point specified by the format, in the order they appear (after the optional leading minus sign) in `digits` or `buf2`. In `digits`, only the optional leading minus sign and the immediately subsequent digit characters (as classified according to `ct`) are used; any trailing characters (including digits appearing after a non-digit character) are ignored. Calls `str.width(0)`.

1 *Remarks:* The currency symbol is generated if and only if `(str.flags() & str.showbase)` is nonzero. If the number of characters generated for the specified format is less than the value returned by

`str.width()` on entry to the function, then copies of `fill` are inserted as necessary to pad to the specified width. For the value `af` equal to `(str.flags() & str.adjustfield)`, if `(af == str.internal)` is true, the fill characters are placed where `none` or `space` appears in the formatting pattern; otherwise if `(af == str.left)` is true, they are placed after the other characters; otherwise, they are placed before the other characters. [*Note:* It is possible, with some combinations of format patterns and flag values, to produce output that cannot be parsed using `num_get<>::get`. — *end note*]

2 *Returns:* An iterator pointing immediately after the last character produced.

22.106.0.1 Class template `moneypunct` [locale.moneypunct]

```
namespace std {
  class money_base {
  public:
    enum part { none, space, symbol, sign, value };
    struct pattern { char field[4]; };
  };

  template <class charT, bool International = false>
  class moneypunct : public locale::facet, public money_base {
  public:
    typedef charT char_type;
    typedef basic_string<charT> string_type;

    explicit moneypunct(size_t refs = 0);

    charT        decimal_point() const;
    charT        thousands_sep() const;
    string       grouping()      const;
    string_type  curr_symbol()   const;
    string_type  positive_sign() const;
    string_type  negative_sign() const;
    int          frac_digits()   const;
    pattern      pos_format()    const;
    pattern      neg_format()    const;

    static locale::id id;
    static const bool intl = International;

  protected:
    ~moneypunct();
    virtual charT        do_decimal_point() const;
    virtual charT        do_thousands_sep() const;
    virtual string       do_grouping()      const;
    virtual string_type  do_curr_symbol()   const;
    virtual string_type  do_positive_sign() const;
    virtual string_type  do_negative_sign() const;
    virtual int          do_frac_digits()   const;
    virtual pattern      do_pos_format()    const;
    virtual pattern      do_neg_format()    const;
  };
}
```

1 The `moneypunct<>` facet defines monetary formatting parameters used by `money_get<>` and `money_put<>`. A monetary format is a sequence of four components, specified by a `pattern` value `p`, such that the `part` value

static_cast<part>(p.field[i]) determines the ith component of the format[255] In the field member of a pattern object, each value symbol, sign, value, and either space or none appears exactly once. The value none, if present, is not first; the value space, if present, is neither first nor last.

2 Where none or space appears, white space is permitted in the format, except where none appears at the end, in which case no white space is permitted. The value space indicates that at least one space is required at that position. Where symbol appears, the sequence of characters returned by curr_symbol() is permitted, and can be required. Where sign appears, the first (if any) of the sequence of characters returned by positive_sign() or negative_sign() (respectively as the monetary value is non-negative or negative) is required. Any remaining characters of the sign sequence are required after all other format components. Where value appears, the absolute numeric monetary value is required.

3

The format of the numeric monetary value is a decimal number:

```
value ::= units [ decimal-point [ digits ]] |
  decimal-point digits
```

if frac_digits() returns a positive value, or

```
value ::= units
```

otherwise. The symbol decimal-point indicates the character returned by decimal_point(). The other symbols are defined as follows:

```
units ::= digits [ thousands-sep units ]
digits ::= adigit [ digits ]
```

In the syntax specification, the symbol adigit is any of the values ct.widen(c) for c in the range '0' through '9', inclusive, and ct is a reference of type const ctype<charT>& obtained as described in the definitions of money_get<> and money_put<>. The symbol thousands-sep is the character returned by thousands_sep(). The space character used is the value ct.widen(' '). White space characters are those characters c for which ci.is(space,c) returns true. The number of digits required after the decimal point (if any) is exactly the value returned by frac_digits().

1 The placement of thousands-separator characters (if any) is determined by the value returned by grouping(), defined identically as the member numpunct<>::do_grouping().

22.107.0.0.1 moneypunct members [locale.moneypunct.members]

```
charT        decimal_point() const;
charT        thousands_sep() const;
string       grouping()      const;
string_type  curr_symbol()   const;
string_type  positive_sign() const;
string_type  negative_sign() const;
int          frac_digits()   const;
pattern      pos_format()    const;
pattern      neg_format()    const;
```

1 Each of these functions F returns the result of calling the corresponding virtual member function do_F().

22.107.0.0.2 moneypunct virtual functions [locale.moneypunct.virtuals]

```
charT do_decimal_point() const;
```

1 *Returns:* The radix separator to use in case do_frac_digits() is greater than zero.[256]

255) An array of char, rather than an array of part, is specified for pattern::field purely for efficiency.
256) In common U.S. locales this is '.'.

```
charT do_thousands_sep() const;
```

2 *Returns:* The digit group separator to use in case `do_grouping()` specifies a digit grouping pattern.[257]

```
string do_grouping() const;
```

3 *Returns:* A pattern defined identically as, but not necessarily equal to, the result of `numpunct<charT>::do_grouping()`.[258]

```
string_type do_curr_symbol() const;
```

4 *Returns:* A string to use as the currency identifier symbol.[259]

```
string_type do_positive_sign() const;
string_type do_negative_sign() const;
```

5 *Returns:* `do_positive_sign()` returns the string to use to indicate a positive monetary value;[260] `do_negative_sign()` returns the string to use to indicate a negative value.

```
int do_frac_digits() const;
```

6 *Returns:* The number of digits after the decimal radix separator, if any.[261]

```
pattern do_pos_format() const;
pattern do_neg_format() const;
```

7 *Returns:* The specializations required in Table 82 (22.6.0.1.1), namely `moneypunct<char>`, `moneypunct<wchar_t>`, `moneypunct<char,true>`, and `moneypunct<wchar_t,true>`, return an object of type `pattern` initialized to `{ symbol, sign, none, value }`.[262]

22.107.0.1 Class template `moneypunct_byname` [locale.moneypunct.byname]

```
namespace std {
  template <class charT, bool Intl = false>
  class moneypunct_byname : public moneypunct<charT, Intl> {
  public:
    typedef money_base::pattern pattern;
    typedef basic_string<charT> string_type;

    explicit moneypunct_byname(const char*, size_t refs = 0);
    explicit moneypunct_byname(const string&, size_t refs = 0);
  protected:
    ~moneypunct_byname();
  };
}
```

22.107.1 The message retrieval category [category.messages]

1 Class `messages<charT>` implements retrieval of strings from message catalogs.

257) In common U.S. locales this is `','`.
258) To specify grouping by 3s, the value is `"\003"` *not* `"3"`.
259) For international specializations (second template parameter `true`) this is typically four characters long, usually three letters and a space.
260) This is usually the empty string.
261) In common U.S. locales, this is 2.
262) Note that the international symbol returned by `do_curr_sym()` usually contains a space, itself; for example, `"USD "`.

22.107.1.1 Class template messages [locale.messages]

```
namespace std {
  class messages_base {
  public:
    typedef unspecified signed integer type catalog;
  };

  template <class charT>
  class messages : public locale::facet, public messages_base {
  public:
    typedef charT char_type;
    typedef basic_string<charT> string_type;

    explicit messages(size_t refs = 0);

    catalog open(const basic_string<char>& fn, const locale&) const;
    string_type get(catalog c, int set, int msgid,
                    const string_type& dfault) const;
    void close(catalog c) const;

    static locale::id id;

  protected:
    ~messages();
    virtual catalog do_open(const basic_string<char>&, const locale&) const;
    virtual string_type do_get(catalog, int set, int msgid,
                               const string_type& dfault) const;
    virtual void do_close(catalog) const;
  };
}
```

1 Values of type `messages_base::catalog` usable as arguments to members `get` and `close` can be obtained only by calling member `open`.

22.107.1.1.1 messages members [locale.messages.members]

```
catalog open(const basic_string<char>& name, const locale& loc) const;
```

1 *Returns:* `do_open(name, loc)`.

```
string_type get(catalog cat, int set, int msgid,
                const string_type& dfault) const;
```

2 *Returns:* `do_get(cat, set, msgid, dfault)`.

```
void  close(catalog cat) const;
```

3 *Effects:* Calls `do_close(cat)`.

22.107.1.1.2 messages virtual functions [locale.messages.virtuals]

```
catalog do_open(const basic_string<char>& name,
                const locale& loc) const;
```

1 *Returns:* A value that may be passed to `get()` to retrieve a message from the message catalog identified by the string `name` according to an implementation-defined mapping. The result can be used until it is passed to `close()`.

2 Returns a value less than 0 if no such catalog can be opened.

3 *Remarks:* The locale argument `loc` is used for character set code conversion when retrieving messages, if needed.

```
string_type do_get(catalog cat, int set, int msgid,
              const string_type& dfault) const;
```

4 *Requires:* `cat` shall be a catalog obtained from `open()` and not yet closed.

5 *Returns:* A message identified by arguments `set`, `msgid`, and `dfault`, according to an implementation-defined mapping. If no such message can be found, returns `dfault`.

```
void do_close(catalog cat) const;
```

6 *Requires:* `cat` shall be a catalog obtained from `open()` and not yet closed.

7 *Effects:* Releases unspecified resources associated with `cat`.

8 *Remarks:* The limit on such resources, if any, is implementation-defined.

22.107.1.2 Class template `messages_byname` [locale.messages.byname]

```
namespace std {
  template <class charT>
  class messages_byname : public messages<charT> {
  public:
    typedef messages_base::catalog catalog;
    typedef basic_string<charT>    string_type;

    explicit messages_byname(const char*, size_t refs = 0);
    explicit messages_byname(const string&, size_t refs = 0);
  protected:
    ~messages_byname();
  };
}
```

22.107.2 Program-defined facets [facets.examples]

1 A C++ program may define facets to be added to a locale and used identically as the built-in facets. To create a new facet interface, C++ programs simply derive from `locale::facet` a class containing a static member: `static locale::id id`.

2 [*Note:* The locale member function templates verify its type and storage class. — *end note*]

3 [*Example:* Traditional global localization is still easy:

```
#include <iostream>
#include <locale>
int main(int argc, char** argv) {
  using namespace std;
  locale::global(locale(""));          // set the global locale
                                       // imbue it on all the std streams
  cin.imbue(locale());
  cout.imbue(locale());
  cerr.imbue(locale());
  wcin.imbue(locale());
  wcout.imbue(locale());
  wcerr.imbue(locale());

  return MyObject(argc, argv).doit();
}
```

— *end example*]

4 [*Example:* Greater flexibility is possible:

```
#include <iostream>
#include <locale>
int main() {
  using namespace std;
  cin.imbue(locale(""));        // the user's preferred locale
  cout.imbue(locale::classic());
  double f;
  while (cin >> f) cout << f << endl;
  return (cin.fail() != 0);
}
```

In a European locale, with input `3.456,78`, output is `3456.78`. — *end example*]

5 This can be important even for simple programs, which may need to write a data file in a fixed format, regardless of a user's preference.

6 [*Example:* Here is an example of the use of locales in a library interface.

```
// file: Date.h
#include <iosfwd>
#include <string>
#include <locale>

class Date {
public:
  Date(unsigned day, unsigned month, unsigned year);
  std::string asString(const std::locale& = std::locale());
};

std::istream& operator>>(std::istream& s, Date& d);
std::ostream& operator<<(std::ostream& s, Date d);
```

7 This example illustrates two architectural uses of class `locale`.

8 The first is as a default argument in `Date::asString()`, where the default is the global (presumably user-preferred) locale.

9 The second is in the operators `<<` and `>>`, where a locale "hitchhikes" on another object, in this case a stream, to the point where it is needed.

```
// file: Date.C
#include "Date"                  // includes <ctime>
#include <sstream>
std::string Date::asString(const std::locale& l) {
  using namespace std;
  ostringstream s; s.imbue(l);
  s << *this; return s.str();
}

std::istream& operator>>(std::istream& s, Date& d) {
  using namespace std;
  istream::sentry cerberos(s);
  if (cerberos) {
    ios_base::iostate err = goodbit;
    struct tm t;
```

```
    use_facet< time_get<char> >(s.getloc()).get_date(s, 0, s, err, &t);
    if (!err) d = Date(t.tm_day, t.tm_mon + 1, t.tm_year + 1900);
    s.setstate(err);
  }
  return s;
}
```

— *end example*]

10 A locale object may be extended with a new facet simply by constructing it with an instance of a class derived from `locale::facet`. The only member a C++ program must define is the static member `id`, which identifies your class interface as a new facet.

11 [*Example:* Classifying Japanese characters:

```
// file: <jctype>
#include <locale>
namespace My {
  using namespace std;
  class JCtype : public locale::facet {
  public:
    static locale::id id;        // required for use as a new locale facet
    bool is_kanji (wchar_t c) const;
    JCtype() { }
  protected:
    ~JCtype() { }
  };
}

// file: filt.C
#include <iostream>
#include <locale>
#include "jctype"                // above
std::locale::id My::JCtype::id; // the static JCtype member declared above.

int main() {
  using namespace std;
  typedef ctype<wchar_t> wctype;
  locale loc(locale(""),         // the user's preferred locale ...
         new My::JCtype);        // and a new feature ...
  wchar_t c = use_facet<wctype>(loc).widen('!');
  if (!use_facet<My::JCtype>(loc).is_kanji(c))
    cout << "no it isn't!" << endl;
  return 0;
}
```

12 The new facet is used exactly like the built-in facets. — *end example*]

13 [*Example:* Replacing an existing facet is even easier. The code does not define a member `id` because it is reusing the `numpunct<charT>` facet interface:

```
// file: my_bool.C
#include <iostream>
#include <locale>
#include <string>
namespace My {
  using namespace std;
  typedef numpunct_byname<char> cnumpunct;
```

```
  class BoolNames : public cnumpunct {
  protected:
    string do_truename()  const { return "Oui Oui!"; }
    string do_falsename() const { return "Mais Non!"; }
    ~BoolNames() { }
  public:
    BoolNames(const char* name) : cnumpunct(name) { }
  };
}

int main(int argc, char** argv) {
  using namespace std;
  // make the user's preferred locale, except for...
  locale loc(locale(""), new My::BoolNames(""));
  cout.imbue(loc);
  cout << boolalpha << "Any arguments today? " << (argc > 1) << endl;
  return 0;
}
```

— *end example*]

22.108 Standard code conversion facets [locale.stdcvt]

1 The header `<codecvt>` provides code conversion facets for various character encodings.

2 **Header `<codecvt>` synopsis**

```
namespace std {
  enum codecvt_mode {
    consume_header = 4,
    generate_header = 2,
    little_endian = 1
  };

  template<class Elem, unsigned long Maxcode = 0x10ffff,
    codecvt_mode Mode = (codecvt_mode)0>
  class codecvt_utf8
    : public codecvt<Elem, char, mbstate_t> {
  public:
    explicit codecvt_utf8(size_t refs = 0);
    ~codecvt_utf8();
  };

  template<class Elem, unsigned long Maxcode = 0x10ffff,
    codecvt_mode Mode = (codecvt_mode)0>
  class codecvt_utf16
    : public codecvt<Elem, char, mbstate_t> {
  public:
    explicit codecvt_utf16(size_t refs = 0);
    ~codecvt_utf16();
  };

  template<class Elem, unsigned long Maxcode = 0x10ffff,
    codecvt_mode Mode = (codecvt_mode)0>
  class codecvt_utf8_utf16
    : public codecvt<Elem, char, mbstate_t> {
  public:
```

```
    explicit codecvt_utf8_utf16(size_t refs = 0);
    ~codecvt_utf8_utf16();
  };
}
```

3

For each of the three code conversion facets `codecvt_utf8`, `codecvt_utf16`, and `codecvt_utf8_utf16`:

— `Elem` is the wide-character type, such as `wchar_t`, `char16_t`, or `char32_t`.

— `Maxcode` is the largest wide-character code that the facet will read or write without reporting a conversion error.

— If `(Mode & consume_header)`, the facet shall consume an initial header sequence, if present, when reading a multibyte sequence to determine the endianness of the subsequent multibyte sequence to be read.

— If `(Mode & generate_header)`, the facet shall generate an initial header sequence when writing a multibyte sequence to advertise the endianness of the subsequent multibyte sequence to be written.

— If `(Mode & little_endian)`, the facet shall generate a multibyte sequence in little-endian order, as opposed to the default big-endian order.

1

For the facet `codecvt_utf8`:

— The facet shall convert between UTF-8 multibyte sequences and UCS2 or UCS4 (depending on the size of `Elem`) within the program.

— Endianness shall not affect how multibyte sequences are read or written.

— The multibyte sequences may be written as either a text or a binary file.

1

For the facet `codecvt_utf16`:

— The facet shall convert between UTF-16 multibyte sequences and UCS2 or UCS4 (depending on the size of `Elem`) within the program.

— Multibyte sequences shall be read or written according to the `Mode` flag, as set out above.

— The multibyte sequences may be written only as a binary file. Attempting to write to a text file produces undefined behavior.

1

For the facet `codecvt_utf8_utf16`:

— The facet shall convert between UTF-8 multibyte sequences and UTF-16 (one or two 16-bit codes) within the program.

— Endianness shall not affect how multibyte sequences are read or written.

— The multibyte sequences may be written as either a text or a binary file.

23 Containers library [containers]

23.1 General [containers.general]

1 This Clause describes components that C++ programs may use to organize collections of information.

2 The following subclauses describe container requirements, and components for sequence containers and associative containers, as summarized in Table 95.

Table 95 — Containers library summary

Subclause		Header(s)
23.2	Requirements	

23.540	Sequence containers	`<array>`
		`<deque>`
		`<forward_list>`
		`<list>`
		`<vector>`

23.894	Associative containers	`<map>` `<set>`
23.932	Unordered associative containers	`<unordered_map>` `<unordered_set>`
23.939	Container adaptors	`<queue>` `<stack>`

23.2 Container requirements [container.requirements]

23.2.1 General container requirements [container.requirements.general]

1

Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.

1

All of the complexity requirements in this Clause are stated solely in terms of the number of operations on the contained objects. [*Example:* the copy constructor of type `vector <vector<int> >` has linear complexity, even though the complexity of copying each contained `vector<int>` is itself linear. — *end example*]

1

For the components affected by this subclause that declare an `allocator_type`, objects stored in these components shall be constructed using the `allocator_traits<allocator_type>::construct` function and destroyed using the `allocator_traits<allocator_type>::destroy` function (20.89.0.1). These functions are called only for the container's element type, not for internal types used by the container. [*Note:* This means, for example, that a node-based container might need to construct nodes containing aligned buffers and call `construct` to place the element into the buffer. — *end note*]

1

In Tables 96, 97, and 98 `X` denotes a container class containing objects of type `T`, `a` and `b` denote values of type `X`, `u` denotes an identifier, `r` denotes a non-const value of type `X`, and `rv` denotes a non-const rvalue of type `X`.

Table 96 — Container requirements

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition	Complexity
`X::value_type`	`T`		*Requires:* `T` is `Erasable` from `X` (see 23.2.1, below)	compile time
`X::reference`	`T&`			compile time
`X::const_reference`	`const T&`			compile time
`X::iterator`	iterator type whose value type is `T`		any iterator category that meets the forward iterator requirements. convertible to `X::const_iterator`.	compile time
`X::const_iterator`	constant iterator type whose value type is `T`		any iterator category that meets the forward iterator requirements.	compile time
`X::difference_type`	signed integer type		is identical to the difference type of `X::iterator` and `X::const_iterator`	compile time
`X::size_type`	unsigned integer type		`size_type` can represent any non-negative value of `difference_type`	compile time
`X u;`			post: `u.empty()`	constant
`X()`			post: `X().empty()`	constant
`X(a)`			*Requires:*`T` is `CopyInsertable` into `X` (see below). post: `a == X(a)`.	linear
`X u(a)` `X u = a;`			*Requires:*`T` is `CopyInsertable` into `X` (see below). post: `u == a`	linear
`X u(rv)` `X u = rv`			post: `u` shall be equal to the value that `rv` had before this construction	(Note B)
`a = rv`	`X&`	All existing elements of `a` are either move assigned to or destroyed	`a` shall be equal to the value that `rv` had before this assignment	linear

Table 96 — Container requirements (continued)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition	Complexity
`(&a)->~X()`	`void`		note: the destructor is applied to every element of `a`; any memory obtained is deallocated.	linear
`a.begin()`	`iterator`; `const_iterator` for constant `a`			constant
`a.end()`	`iterator`; `const_iterator` for constant `a`			constant
`a.cbegin()`	`const_iterator`	`const_cast<X const&>(a).begin();`		constant
`a.cend()`	`const_iterator`	`const_cast<X const&>(a).end();`		constant
`a == b`	convertible to `bool`	`==` is an equivalence relation. `equal(a.begin(), a.end(), b.begin(), b.end())`	*Requires:* `T` is `EqualityComparable`	Constant if `a.size() != b.size()`, linear otherwise
`a != b`	convertible to `bool`	Equivalent to: `!(a == b)`		linear
`a.swap(b)`	`void`		exchanges the contents of `a` and `b`	(Note A)
`swap(a, b)`	`void`	`a.swap(b)`		(Note A)
`r = a`	`X&`		post: `r == a`.	linear
`a.size()`	`size_type`	`distance(a.begin(), a.end())`		constant
`a.max_size()`	`size_type`	`distance(begin(), end())` for the largest possible container		constant
`a.empty()`	convertible to `bool`	`a.begin() == a.end()`		constant

Notes: the algorithm `equal()` is defined in Clause 25. Those entries marked "(Note A)" or "(Note B)" have linear complexity for `array` and have constant complexity for all other standard containers.

1

The member function `size()` returns the number of elements in the container. The number of elements is defined by the rules of constructors, inserts, and erases.

1

`begin()` returns an iterator referring to the first element in the container. `end()` returns an iterator which is the past-the-end value for the container. If the container is empty, then `begin() == end()`;

1

In the expressions

```
i == j
i != j
i < j
i <= j
i >= j
i > j
i - j
```

where `i` and `j` denote objects of a container's `iterator` type, either or both may be replaced by an object of the container's `const_iterator` type referring to the same element with no change in semantics.

1

Unless otherwise specified, all containers defined in this clause obtain memory using an allocator (see 17.165.0.1). Copy constructors for these container types obtain an allocator by calling `allocator_traits<allocator_type>::select_on_container_copy_construction` on the allocator belonging to the container being copied. Move constructors obtain an allocator by move construction from the allocator belonging to the container being moved. Such move construction of the allocator shall not exit via an exception. All other constructors for these container types take a `const allocator_type&` argument. [*Note:* If an invocation of a constructor uses the default value of an optional allocator argument, then the `Allocator` type must support value initialization. — *end note*] A copy of this allocator is used for any memory allocation performed, by these constructors and by all member functions, during the lifetime of each container object or until the allocator is replaced. The allocator may be replaced only via assignment or `swap()`. Allocator replacement is performed by copy assignment, move assignment, or swapping of the allocator only if `allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value`, `allocator_traits<allocator_type>::propagate_on_container_move_assignment::value`, or `allocator_traits<allocator_type>::propagate_on_container_swap::value` is true within the implementation of the corresponding container operation. The behavior of a call to a container's `swap` function is undefined unless the objects being swapped have allocators that compare equal or `allocator_traits<allocator_type>::propagate_on_container_swap::value` is true. In all container types defined in this Clause, the member `get_allocator()` returns a copy of the allocator used to construct the container or, if that allocator has been replaced, a copy of the most recent replacement.

1

The expression `a.swap(b)`, for containers `a` and `b` of a standard container type other than `array`, shall exchange the values of `a` and `b` without invoking any move, copy, or swap operations on the individual container elements. Any `Compare`, `Pred`, or `Hash` objects belonging to `a` and `b` shall be swappable and shall be exchanged by unqualified calls to non-member `swap`. If `allocator_traits<allocator_type>::propagate_on_container_swap::value` is `true`, then the allocators of `a` and `b` shall also be exchanged using an unqualified call to non-member `swap`. Otherwise, they shall not be swapped, and the behavior is undefined unless `a.get_allocator() == b.get_allocator()`. Every iterator referring to an element in one container before the swap shall refer to the same element in the other container after the swap. It is unspecified whether an iterator with value `a.end()` before the swap will have value `b.end()` after the swap.

1 If the iterator type of a container belongs to the bidirectional or random access iterator categories (24.2), the container is called *reversible* and satisfies the additional requirements in Table 97.

Table 97 — Reversible container requirements

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`X::reverse_iterator`	iterator type whose value type is `T`	`reverse_iterator<iterator>`	compile time
`X::const_reverse_iterator`	constant iterator type whose value type is `T`	`reverse_iterator<const_iterator>`	compile time
`a.rbegin()`	`reverse_iterator`; `const_reverse_iterator` for constant `a`	`reverse_iterator(end())`	constant
`a.rend()`	`reverse_iterator`; `const_reverse_iterator` for constant `a`	`reverse_iterator(begin())`	constant
`a.crbegin()`	`const_reverse_iterator`	`const_cast<X const&>(a).rbegin()`	constant
`a.crend()`	`const_reverse_iterator`	`const_cast<X const&>(a).rend()`	constant

2

Unless otherwise specified (see 23.431.0.1, 23.539.0.1, 23.610.0.1, and 23.806.0.1) all container types defined in this Clause meet the following additional requirements:

— if an exception is thrown by an `insert()` or `emplace()` function while inserting a single element, that function has no effects.

— if an exception is thrown by a `push_back()`, `push_front()`, `emplace_back()`, or `emplace_front()` function, that function has no effects.

— no `erase()`, `clear()`, `pop_back()` or `pop_front()` function throws an exception.

— no copy constructor or assignment operator of a returned iterator throws an exception.

— no `swap()` function throws an exception.

— no `swap()` function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped. [*Note:* The `end()` iterator does not refer to any element, so it may be invalidated. — *end note*]

1

Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

1

Table 98 lists operations that are provided for some types of containers but not others. Those containers for which the listed operations are provided shall implement the semantics described in Table 98 unless otherwise stated.

Table 98 — Optional container operations

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition	Complexity
`a < b`	convertible to `bool`	`lexicographical_compare(a.begin(), a.end(), b.begin(), b.end())`	pre: `<` is defined for values of `T`. `<` is a total ordering relationship.	linear
`a > b`	convertible to `bool`	`b < a`		linear
`a <= b`	convertible to `bool`	`!(a > b)`		linear
`a >= b`	convertible to `bool`	`!(a < b)`		linear

Note: the algorithm `lexicographical_compare()` is defined in Clause 25.

1

All of the containers defined in this Clause and in (21.28) except `array` meet the additional requirements of an allocator-aware container, as described in Table 99.

Given a container type `X` having an `allocator_type` identical to `A` and a `value_type` identical to `T` and given an lvalue `m` of type `A`, a pointer `p` of type `T*`, an expression `v` of type (possibly const) `T`, and an rvalue `rv` of type `T`, the following terms are defined. If `X` is not allocator-aware, the terms below are defined as if `A` were `std::allocator<T>` — no allocator object needs to be created and user specializations of `std::allocator<T>` are not instantiated:

— `T` is *`DefaultInsertable` into `X`* means that the following expression is well-formed:

```
allocator_traits<A>::construct(m, p)
```

— An element of `X` is *default-inserted* if it is initialized by evaluation of the expression

```
allocator_traits<A>::construct(m, p)
```

where `p` is the address of the uninitialized storage for the element allocated within `X`.

— `T` is *`MoveInsertable` into `X`* means that the following expression is well-formed:

```
allocator_traits<A>::construct(m, p, rv)
```

and its evaluation causes the following postcondition to hold: The value of `*p` is equivalent to the value of `rv` before the evaluation. [*Note:* rv remains a valid object. Its state is unspecified — *end note*]

— `T` is *`CopyInsertable` into `X`* means that, in addition to `T` being `MoveInsertable` into `X`, the following expression is well-formed:

```
allocator_traits<A>::construct(m, p, v)
```

and its evaluation causes the following postcondition to hold: The value of `v` is unchanged and is equivalent to `*p`.

— `T` is *`EmplaceConstructible` into `X` from `args`*, for zero or more arguments `args`, means that the following expression is well-formed:

```
allocator_traits<A>::construct(m, p, args)
```

— `T` is *`Erasable` from `X`* means that the following expression is well-formed:

```
allocator_traits<A>::destroy(m, p)
```

[*Note:* A container calls `allocator_traits<A>::construct(m, p, args)` to construct an element at `p` using `args`. The default `construct` in `std::allocator` will call `::new((void*)p) T(args)`, but specialized allocators may choose a different definition. — *end note*]

1

In Table 99, `X` denotes an allocator-aware container class with a `value_type` of `T` using allocator of type `A`, `u` denotes a variable, `a` and `b` denote non-const lvalues of type `X`, `t` denotes an lvalue or a const rvalue of type `X`, `rv` denotes a non-const rvalue of type `X`, and `m` is a value of type `A`.

Table 99 — Allocator-aware container requirements

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`allocator_type`	`A`	*Requires:* `allocator_type::value_type` is the same as `X::value_type`.	compile time
`get_allocator()`	`A`		constant
`X()` `X u;`		*Requires:* `A` is `DefaultConstructible`. post: `u.empty()` returns `true`, `u.get_allocator() == A()`	constant
`X(m)` `X u(m);`		post: `u.empty()` returns `true`, `u.get_allocator() == m`	constant
`X(t, m)` `X u(t, m);`		*Requires:* `T` is `CopyInsertable` into `X`. post: `u == t`, `u.get_allocator() == m`	linear
`X(rv)` `X u(rv)`		*Requires:* move construction of `A` shall not exit via an exception. post: `u` shall have the same elements as `rv` had before this construction; the value of `u.get_allocator()` shall be the same as the value of `rv.get_allocator()` before this construction.	constant
`X(rv, m)` `X u(rv, m);`		*Requires:* `T` is `MoveInsertable` into `X`. post: `u` shall have the same elements, or copies of the elements, that `rv` had before this construction, `u.get_allocator() == m`	constant if `m == rv.get_allocator()`, otherwise linear

Table 99 — Allocator-aware container requirements (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`a = t`	`X&`	*Requires:* `T` is `CopyInsertable` into `X` and `CopyAssignable`. post: `a == t`	linear
`a = rv`	`X&`	*Requires:* If `allocator_traits<allocator_type>::propagate_on_container_move_assignment::value` is `false`, `T` is `MoveInsertable` into `X` and `MoveAssignable`. All existing elements of `a` are either move assigned to or destroyed. post: `a` shall be equal to the value that `rv` had before this assignment.	linear
`a.swap(b)`	`void`	exchanges the contents of `a` and `b`	constant

23.184.1 Container data races [container.requirements.dataraces]

1

For purposes of avoiding data races (17.607.0.1), implementations shall consider the following functions to be `const`: `begin`, `end`, `rbegin`, `rend`, `front`, `back`, `data`, `find`, `lower_bound`, `upper_bound`, `equal_range`, `at` and, except in associative or unordered associative containers, `operator[]`.

1

Notwithstanding (17.607.0.1), implementations are required to avoid data races when the contents of the contained object in different elements in the same container, excepting `vector<bool>`, are modified concurrently.

1

[*Note:* For a `vector<int> x` with a size greater than one, `x[1] = 5` and `*x.begin() = 10` can be executed concurrently without a data race, but `x[0] = 5` and `*x.begin() = 10` executed concurrently may result in a data race. As an exception to the general rule, for a `vector<bool> y`, `y[0] = true` may race with `y[1] = true`. — *end note*]

23.224.1 Sequence containers [sequence.reqmts]

1

A sequence container organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides four basic kinds of sequence containers: `vector`, `forward_list`, `list`, and `deque`. In addition, `array` is provided as a sequence container which provides limited sequence operations because it has a fixed number of elements. The library also provides container adaptors that make it easy to construct abstract data types, such as `stack`s or `queue`s, out of the basic sequence container kinds (or out of other kinds of sequence containers that the user might define).

1

The sequence containers offer the programmer different complexity trade-offs and should be used accordingly. `vector` or `array` is the type of sequence container that should be used by default. `list` or `forward_list` should be used when there are frequent insertions and deletions from the middle of the sequence. `deque` is the data structure of choice when most insertions and deletions take place at the beginning or at the end of the sequence.

1

In Tables 100 and 101, `X` denotes a sequence container class, `a` denotes a value of `X` containing elements of type `T`, `A` denotes `X::allocator_type` if it exists and `std::allocator<T>` if it doesn't, `i` and `j` denote iterators satisfying input iterator requirements and refer to elements implicitly convertible to `value_type`, `[i, j)` denotes a valid range, `il` designates an object of type `initializer_list<value_type>`, `n` denotes a value of `X::size_type`, `p` denotes a valid const iterator to `a`, `q` denotes a valid dereferenceable const iterator to `a`, `[q1, q2)` denotes a valid range of const iterators in `a`, `t` denotes an lvalue or a const rvalue of `X::value_type`, and `rv` denotes a non-const rvalue of `X::value_type`. `Args` denotes a template parameter pack; `args` denotes a function parameter pack with the pattern `Args&&`.

1

The complexities of the expressions are sequence dependent.

Table 100 — Sequence container requirements (in addition to container)

Expression	Return type	Assertion/note pre-/post-condition
`X(n, t)` `X a(n, t)`		*Requires:* `T` shall be `CopyInsertable` into `X`. post: `distance(begin(), end()) == n` Constructs a sequence container with `n` copies of `t`
`X(i, j)` `X a(i, j)`		*Requires:* `T` shall be `EmplaceConstructible` into `X` from `*i`. For `vector`, if the iterator does not meet the forward iterator requirements (24.122.1), `T` shall also be `MoveInsertable` into `X`. Each iterator in the range `[i,j)` shall be dereferenced exactly once. post: `distance(begin(), end()) == distance(i, j)` Constructs a sequence container equal to the range `[i, j)`
`X(il);`		Equivalent to `X(il.begin(), il.end())`
`a = il;`	`X&`	*Requires:* `T` is `CopyInsertable` into `X` and `CopyAssignable`. Assigns the range `[il.begin(),il.end())` into `a`. All existing elements of `a` are either assigned to or destroyed. *Returns:* `*this`.

Table 100 — Sequence container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition
`a.emplace(p, args);`	`iterator`	*Requires:* `T` is `EmplaceConstructible` into `X` from `args`. For `vector` and `deque`, T is also `MoveInsertable` into `X` and `MoveAssignable`. *Effects:* Inserts an object of type `T` constructed with `std::forward<Args>(args)...` before `p`.
`a.insert(p,t)`	`iterator`	*Requires:*`T` shall be `CopyInsertable` into `X`. For `vector` and `deque`, `T` shall also be `CopyAssignable`. *Effects:* Inserts a copy of `t` before `p`.
`a.insert(p,rv)`	`iterator`	*Requires:* `T` shall be `MoveInsertable` into `X`. For `vector` and `deque`, `T` shall also be `MoveAssignable`. *Effects:* Inserts a copy of `rv` before `p`.
`a.insert(p,n,t)`	`iterator`	*Requires:*`T` shall be `CopyInsertable` into `X` and `CopyAssignable`. Inserts `n` copies of `t` before `p`.
`a.insert(p,i,j)`	`iterator`	*Requires:*`T` shall be `EmplaceConstructible` into `X` from `*i`. For `vector`, if the iterator does not meet the forward iterator requirements (24.122.1), `T` shall also be `MoveInsertable` into `X` and `MoveAssignable`. Each iterator in the range `[i,j)` shall be dereferenced exactly once. pre: `i` and `j` are not iterators into `a`. Inserts copies of elements in `[i, j)` before `p`
`a.insert(p, il);`	`iterator`	`a.insert(p, il.begin(), il.end())`.
`a.erase(q)`	`iterator`	*Requires:* For `vector` and `deque`, `T` shall be `MoveAssignable`. *Effects:* Erases the element pointed to by `q`
`a.erase(q1,q2)`	`iterator`	*Requires:* For `vector` and `deque`, `T` shall be `MoveAssignable`. *Effects:* Erases the elements in the range `[q1, q2)`.
`a.clear()`	`void`	Destroys all elements in `a`. Invalidates all references, pointers, and iterators referring to the elements of `a` and may invalidate the past-the-end iterator. post: `a.empty()` returns `true`. *Complexity:* Linear.

Table 100 — Sequence container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition
`a.assign(i,j)`	`void`	*Requires:* `T` shall be `EmplaceConstructible` into `X` from `*i` and assignable from `*i`. For `vector`, if the iterator does not meet the forward iterator requirements (24.122.1), `T` shall also be `MoveInsertable` into `X`. Each iterator in the range `[i,j)` shall be dereferenced exactly once. pre: `i`, `j` are not iterators into `a`. Replaces elements in `a` with a copy of `[i, j)`.
`a.assign(il)`	`void`	`a.assign(il.begin(), il.end())`.
`a.assign(n,t)`	`void`	*Requires:* `T` shall be `CopyInsertable` into `X` and `CopyAssignable`. pre: `t` is not a reference into `a`. Replaces elements in `a` with `n` copies of `t`.

1

`iterator` and `const_iterator` types for sequence containers shall be at least of the forward iterator category.

1 The iterator returned from `a.insert(p, t)` points to the copy of `t` inserted into `a`.

2 The iterator returned from `a.insert(p, rv)` points to the copy of `rv` inserted into `a`.

3

The iterator returned from `a.insert(p, n, t)` points to the copy of the first element inserted into `a`, or `p` if `n == 0`.

1 The iterator returned from `a.insert(p, i, j)` points to the copy of the first element inserted into `a`, or `p` if `i == j`.

2 The iterator returned from `a.insert(p, il)` points to the copy of the first element inserted into `a`, or `p` if `il` is empty.

3

The iterator returned from `a.emplace(p, args)` points to the new element constructed from `args` into `a`.

1

The iterator returned from `a.erase(q)` points to the element immediately following `q` prior to the element being erased. If no such element exists, `a.end()` is returned.

1 The iterator returned by `a.erase(q1,q2)` points to the element pointed to by `q2` prior to any elements being erased. If no such element exists, `a.end()` is returned.

2

For every sequence container defined in this Clause and in Clause 21:

— If the constructor

```
template <class InputIterator>
X(InputIterator first, InputIterator last,
  const allocator_type& alloc = allocator_type())
```

is called with a type `InputIterator` that does not qualify as an input iterator, then the constructor shall not participate in overload resolution.

— If the member functions of the forms:

```
template <class InputIterator>          // such as insert()
rt fx1(const_iterator p, InputIterator first, InputIterator last);

template <class InputIterator>          // such as append(), assign()
rt fx2(InputIterator first, InputIterator last);

template <class InputIterator>          // such as replace()
rt fx3(const_iterator i1, const_iterator i2, InputIterator first, InputIterator last);
```

are called with a type `InputIterator` that does not qualify as an input iterator, then these functions shall not participate in overload resolution.

1

The extent to which an implementation determines that a type cannot be an input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators.

1

Table 101 lists operations that are provided for some types of sequence containers but not others. An implementation shall provide these operations for all container types shown in the "container" column, and shall implement them so as to take amortized constant time.

Table 101 — Optional sequence container operations

Expression	Return type	Operational semantics	Container
`a.front()`	`reference; const_reference` for constant `a`	`*a.begin()`	`basic_string`, `array`, `deque`, `forward_list`, `list`, `vector`

`a.back()`	`reference; const_reference` for constant `a`	`{ auto tmp = a.end();`
		`--tmp;`
		`return *tmp; }`
			`basic_string`, `array`, `deque`, `list`, `vector`

`a.emplace_front(args)`	`void`	Prepends an object of type `T` constructed with `std::forward<Args>(args)....` *Requires:* `T` shall be `EmplaceConstructible` into `X` from `args`.	`deque`, `forward_list`, `list`

Table 101 — Optional sequence container operations (continued)

Expression	Return type	Operational semantics	Container
a.emplace_back(args)	void	Appends an object of type T constructed with std::forward<Args>(args).... *Requires:* T shall be EmplaceConstructible into X from args. For vector, T shall also be MoveInsertable into X.	deque, list, vector
a.push_front(t)	void	Prepends a copy of t. *Requires:* T shall be CopyInsertable into X.	deque, forward_list, list
a.push_front(rv)	void	Prepends a copy of rv. *Requires:* T shall be MoveInsertable into X.	deque, forward_list, list
a.push_back(t)	void	Appends a copy of t. *Requires:* T shall be CopyInsertable into X.	basic_string, deque, list, vector
a.push_back(rv)	void	Appends a copy of rv. *Requires:* T shall be MoveInsertable into X.	basic_string, deque, list, vector
a.pop_front()	void	Destroys the first element. *Requires:* a.empty() shall be false.	deque, forward_list, list
a.pop_back()	void	Destroys the last element. *Requires:* a.empty() shall be false.	basic_string, deque, list, vector
a[n]	reference; const_reference for constant a	*(a.begin() + n)	basic_string, array, deque, vector
a.at(n)	reference; const_reference for constant a	*(a.begin() + n)	basic_string, array, deque, vector

1 The member function at() provides bounds-checked access to container elements. at() throws out_of_range if n >= a.size().

23.294.1 Associative containers [associative.reqmts]

1

Associative containers provide fast retrieval of data based on keys. The library provides four basic kinds of associative containers: `set`, `multiset`, `map` and `multimap`.

1

Each associative container is parameterized on `Key` and an ordering relation `Compare` that induces a strict weak ordering (25.98) on elements of `Key`. In addition, `map` and `multimap` associate an arbitrary *mapped type* `T` with the `Key`. The object of type `Compare` is called the *comparison object* of a container.

1

The phrase "equivalence of keys" means the equivalence relation imposed by the comparison and *not* the `operator==` on keys. That is, two keys `k1` and `k2` are considered to be equivalent if for the comparison object `comp`, `comp(k1, k2) == false && comp(k2, k1) == false`. For any two keys `k1` and `k2` in the same container, calling `comp(k1, k2)` shall always return the same value.

1

An associative container supports *unique keys* if it may contain at most one element for each key. Otherwise, it supports *equivalent keys*. The `set` and `map` classes support unique keys; the `multiset` and `multimap` classes support equivalent keys. For `multiset` and `multimap`, `insert`, `emplace`, and `erase` preserve the relative ordering of equivalent elements.

1

For `set` and `multiset` the value type is the same as the key type. For `map` and `multimap` it is equal to `pair<const Key, T>`.

1

`iterator` of an associative container is of the bidirectional iterator category. For associative containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type. [*Note:* `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the One Definition Rule by always using `const_iterator` in their function parameter lists. — *end note*]

1

The associative containers meet all the requirements of Allocator-aware containers (23.2.1), except that for `map` and `multimap`, the requirements placed on `value_type` in Table 96 apply instead to `key_type` and `mapped_type`. [*Note:* For example, in some cases `key_type` and `mapped_type` are required to be `CopyAssignable` even though the associated `value_type`, `pair<const key_type, mapped_type>`, is not `CopyAssignable`. — *end note*]

1

In Table 102, `X` denotes an associative container class, `a` denotes a value of `X`, `a_uniq` denotes a value of `X` when `X` supports unique keys, `a_eq` denotes a value of `X` when `X` supports multiple keys, `a_tran` denotes a value of `X` when the qualified-id `X::key_compare::is_transparent` is valid and denotes a type (14.2114.1), `i` and `j` satisfy input iterator requirements and refer to elements implicitly convertible to `value_type`, `[i,j)` denotes a valid range, `p` denotes a valid const iterator to `a`, `q` denotes a valid dereferenceable const iterator to `a`, `[q1, q2)` denotes a valid range of const iterators in `a`, `il` designates an object of type `initializer_list<value_type>`, `t` denotes a value of `X::value_type`, `k` denotes a value of `X::key_type` and `c` denotes a value of type `X::key_compare`; `kl` is a value such that `a` is partitioned (25.98) with respect to `c(r, kl)`, with `r` the key value of `e` and `e` in `a`; `ku` is a value such that `a` is partitioned with respect to `!c(ku, r)`; `ke` is a value such that `a` is partitioned with respect to `c(r, ke)` and `!c(ke, r)`, with `c(r, ke)` implying `!c(ke, r)`. `A` denotes the storage allocator used by `X`, if any, or `std::allocator<X::value_type>` otherwise, and `m` denotes an allocator of a type convertible to `A`.

Table 102 — Associative container requirements (in addition to container)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`X::key_type`	`Key`		compile time
`mapped_type` (`map` and `multimap` only)	`T`		compile time
`X::value_type` (`set` and `multiset` only)	`Key`	*Requires:* `value_type` is `Erasable` from `X`	compile time
`X::value_type` (`map` and `multimap` only)	`pair<const Key, T>`	*Requires:* `value_type` is `Erasable` from `X`	compile time
`X::key_compare`	`Compare`	defaults to `less<key_type>`	compile time
`X::value_compare`	a binary predicate type	is the same as `key_compare` for `set` and `multiset`; is an ordering relation on pairs induced by the first component (i.e., `Key`) for `map` and `multimap`.	compile time
`X(c)` `X a(c);`		*Requires:* `key_compare` is `CopyConstructible`. *Effects:* Constructs an empty container. Uses a copy of `c` as a comparison object.	constant
`X()` `X a;`		*Requires:* `key_compare` is `DefaultConstructible`. *Effects:* Constructs an empty container. Uses `Compare()` as a comparison object	constant
`X(i,j,c)` `X a(i,j,c);`		*Requires:* `key_compare` is `CopyConstructible`. `value_type` is `EmplaceConstructible` into `X` from `*i`. *Effects:* Constructs an empty container and inserts elements from the range `[i, j)` into it; uses `c` as a comparison object.	$N \log N$ in general (N has the value `distance(i, j)`); linear if `[i, j)` is sorted with `value_comp()`

Table 102 — Associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`X(i,j)` `X a(i,j);`		*Requires:* `key_compare` is `DefaultConstructible`. `value_type` is `EmplaceConstructible` into `X` from `*i`. *Effects:* Same as above, but uses `Compare()` as a comparison object	same as above
`X(il);`		Same as `X(il.begin(), il.end())`.	Same as `X(il.begin(), il.end())`.
`X(il,c);`		Same as `X(il.begin(), il.end(), c)`.	Same as `X(il.begin(), il.end(), c)`.
`a = il`	`X&`	*Requires:* `value_type` is `CopyInsertable` into `X` and `CopyAssignable`. *Effects:* Assigns the range `[il.begin(),il.end())` into `a`. All existing elements of `a` are either assigned to or destroyed.	$NlogN$ in general (where N has the value `il.size() + a.size()`); linear if `[il.begin(),il.end())` is sorted with `value_comp()`.
`a.key_-comp()`	`X::key_-compare`	returns the comparison object out of which `a` was constructed.	constant
`a.value_-comp()`	`X::value_-compare`	returns an object of `value_compare` constructed out of the comparison object	constant
`a_uniq.emplace(args)`	`pair<iterator, bool>`	*Requires:* `value_type` shall be `EmplaceConstructible` into `X` from `args`. *Effects:* Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...` if and only if there is no element in the container with key equivalent to the key of `t`. The `bool` component of the returned pair is true if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of `t`.	logarithmic

Table 102 — Associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`a_eq.emplace(args)`	`iterator`	*Requires:* `value_type` shall be `EmplaceConstructible` into `X` from `args`. *Effects:* Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...` and returns the iterator pointing to the newly inserted element. If a range containing elements equivalent to `t` exists in `a_eq`, `t` is inserted at the end of that range.	logarithmic
`a.emplace_hint(p, args)`	`iterator`	equivalent to `a.emplace(std::forward<Args>(args)...)` Return value is an iterator pointing to the element with the key equivalent to the newly inserted element. The element is inserted as close as possible to the position just prior to `p`.	logarithmic in general, but amortized constant if the element is inserted right before `p`
`a_uniq.insert(t)`	`pair<iterator, bool>`	*Requires:* If `t` is a non-const rvalue expression, `value_type` shall be `MoveInsertable` into `X`; otherwise, `value_type` shall be `CopyInsertable` into `X`. *Effects:* Inserts `t` if and only if there is no element in the container with key equivalent to the key of `t`. The `bool` component of the returned pair is true if and only if the insertion takes place, and the `iterator` component of the pair points to the element with key equivalent to the key of `t`.	logarithmic

Table 102 — Associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`a_eq.insert(t)`	`iterator`	*Requires:* If `t` is a non-const rvalue expression, `value_type` shall be `MoveInsertable` into `X`; otherwise, `value_type` shall be `CopyInsertable` into `X`. *Effects:* Inserts `t` and returns the iterator pointing to the newly inserted element. If a range containing elements equivalent to `t` exists in `a_eq`, `t` is inserted at the end of that range.	logarithmic
`a.insert(p, t)`	`iterator`	*Requires:* If `t` is a non-const rvalue expression, `value_type` shall be `MoveInsertable` into `X`; otherwise, `value_type` shall be `CopyInsertable` into `X`. *Effects:* Inserts `t` if and only if there is no element with key equivalent to the key of `t` in containers with unique keys; always inserts `t` in containers with equivalent keys. Always returns the iterator pointing to the element with key equivalent to the key of `t`. `t` is inserted as close as possible to the position just prior to `p`.	logarithmic in general, but amortized constant if `t` is inserted right before `p`.
`a.insert(i, j)`	`void`	*Requires:* `value_type` shall be `EmplaceConstructible` into `X` from `*i`. pre: `i`, `j` are not iterators into `a`. inserts each element from the range `[i,j)` if and only if there is no element with key equivalent to the key of that element in containers with unique keys; always inserts that element in containers with equivalent keys.	$N \log(\text{a.size}() + N)$ (N has the value `distance(i, j)`
`a.insert(il)`	`void`	Equivalent to `a.insert(il.begin(), il.end())`.	

Table 102 — Associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`a.erase(k)`	`size_type`	erases all elements in the container with key equivalent to `k`. returns the number of erased elements.	log(a.size()) + a.count(k)
`a.erase(q)`	`iterator`	erases the element pointed to by `q`. Returns an iterator pointing to the element immediately following `q` prior to the element being erased. If no such element exists, returns `a.end()`.	amortized constant
`a.erase( q1, q2)`	`iterator`	erases all the elements in the range `[q1,q2)`. Returns an iterator pointing to the element pointed to by q2 prior to any elements being erased. If no such element exists, `a.end()` is returned.	log(a.size()) + N where N has the value `distance(q1, q2)`.
`a.clear()`	`void`	`a.erase(a.begin(),a.end())` post: `a.empty()` returns `true`	linear in `a.size()`.
`a.find(k)`	`iterator`; `const_-iterator` for constant `a`.	returns an iterator pointing to an element with the key equivalent to `k`, or `a.end()` if such an element is not found	logarithmic
`a_tran. find(ke)`	`iterator`; `const_-iterator` for constant `a_tran`.	returns an iterator pointing to an element with key `r` such that `!c(r, ke) && !c(ke, r)`, or `a_tran.end()` if such an element is not found	logarithmic
`a.count(k)`	`size_type`	returns the number of elements with key equivalent to `k`	log(a.size()) + a.count(k)
`a_tran. count(ke)`	`size_type`	returns the number of elements with key `r` such that `!c(r, ke) && !c(ke, r)`	log(a_tran.size()) + a_tran.count(ke)
`a.lower_-bound(k)`	`iterator`; `const_-iterator` for constant `a`.	returns an iterator pointing to the first element with key not less than `k`, or `a.end()` if such an element is not found.	logarithmic
`a_tran. lower_-bound(kl)`	`iterator`; `const_-iterator` for constant `a_tran`.	returns an iterator pointing to the first element with key `r` such that `!c(r, kl)`, or `a_tran.end()` if such an element is not found.	logarithmic

Table 102 — Associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`a.upper_bound(k)`	`iterator`; `const_iterator` for constant `a`.	returns an iterator pointing to the first element with key greater than `k`, or `a.end()` if such an element is not found.	logarithmic
`a_tran.upper_bound(ku)`	`iterator`; `const_iterator` for constant `a_tran`.	returns an iterator pointing to the first element with key `r` such that `c(ku, r)`, or `a_tran.end()` if such an element is not found.	logarithmic
`a.equal_range(k)`	`pair<iterator, iterator>`; `pair<const_iterator, const_iterator>` for constant `a`.	equivalent to `make_pair(a.lower_bound(k), a.upper_bound(k))`.	logarithmic
`a_tran.equal_range(ke)`	`pair<iterator, iterator>`; `pair<const_iterator, const_iterator>` for constant `a_tran`.	equivalent to `make_pair(a_tran.lower_bound(ke), a_tran.upper_bound(ke))`.	logarithmic

1

The `insert` and `emplace` members shall not affect the validity of iterators and references to the container, and the `erase` members shall invalidate only iterators and references to the erased elements.

1

The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators `i` and `j` such that distance from `i` to `j` is positive,

```
value_comp(*j, *i) == false
```

1

For associative containers with unique keys the stronger condition holds,

```
value_comp(*i, *j) != false.
```

1

When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, either through a copy constructor or an assignment operator, the target container shall

then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.

1

The member function templates `find`, `count`, `lower_bound`, `upper_bound`, and `equal_range` shall not participate in overload resolution unless the qualified-id `Compare::is_transparent` is valid and denotes a type (14.2114.1).

23.431.0.1 Exception safety guarantees [associative.reqmts.except]

1

For associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container's `Compare` object (if any).

1

For associative containers, if an exception is thrown by any operation from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

1

For associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container's `Compare` object (if any).

23.437.1 Unordered associative containers [unord.req]

1

Unordered associative containers provide an ability for fast retrieval of data based on keys. The worst-case complexity for most operations is linear, but the average case is much faster. The library provides four unordered associative containers: `unordered_set`, `unordered_map`, `unordered_multiset`, and `unordered_multimap`.

1 Unordered associative containers conform to the requirements for Containers (23.2), except that the expressions `a == b` and `a != b` have different semantics than for the other container types.

2

Each unordered associative container is parameterized by `Key`, by a function object type `Hash` that meets the `Hash` requirements (17.159.0.1) and acts as a hash function for argument values of type `Key`, and by a binary predicate `Pred` that induces an equivalence relation on values of type `Key`. Additionally, `unordered_map` and `unordered_multimap` associate an arbitrary *mapped type* `T` with the `Key`.

1

The container's object of type `Hash` — denoted by `hash` — is called the *hash function* of the container. The container's object of type `Pred` — denoted by `pred` — is called the *key equality predicate* of the container.

1

Two values `k1` and `k2` of type `Key` are considered equivalent if the container's key equality predicate returns `true` when passed those values. If `k1` and `k2` are equivalent, the container's hash function shall return the same value for both. [*Note:* Thus, when an unordered associative container is instantiated with a non-default `Pred` parameter it usually needs a non-default `Hash` parameter as well. — *end note*] For any two keys `k1` and `k2` in the same container, calling `pred(k1, k2)` shall always return the same value. For any key `k` in a container, calling `hash(k)` shall always return the same value.

1

An unordered associative container supports *unique keys* if it may contain at most one element for each key. Otherwise, it supports *equivalent keys*. `unordered_set` and `unordered_map` support unique keys.

`unordered_multiset` and `unordered_multimap` support equivalent keys. In containers that support equivalent keys, elements with equivalent keys are adjacent to each other in the iteration order of the container. Thus, although the absolute order of elements in an unordered container is not specified, its elements are grouped into *equivalent-key groups* such that all elements of each group have equivalent keys. Mutating operations on unordered containers shall preserve the relative order of elements within each equivalent-key group unless otherwise specified.

1 For `unordered_set` and `unordered_multiset` the value type is the same as the key type. For `unordered_map` and `unordered_multimap` it is `std::pair<const Key, T>`.

2 For unordered containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type. [*Note:* `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the One Definition Rule by always using `const_iterator` in their function parameter lists. — *end note*]

3

The elements of an unordered associative container are organized into *buckets*. Keys with the same hash code appear in the same bucket. The number of buckets is automatically increased as elements are added to an unordered associative container, so that the average number of elements per bucket is kept below a bound. Rehashing invalidates iterators, changes ordering between elements, and changes which buckets elements appear in, but does not invalidate pointers or references to elements. For `unordered_multiset` and `unordered_multimap`, rehashing preserves the relative ordering of equivalent elements.

1 The unordered associative containers meet all the requirements of Allocator-aware containers (23.2.1), except that for `unordered_map` and `unordered_multimap`, the requirements placed on `value_type` in Table 96 apply instead to `key_type` and `mapped_type`. [*Note:* For example, `key_type` and `mapped_type` are sometimes required to be `CopyAssignable` even though the associated `value_type`, `pair<const key_type, mapped_type>`, is not `CopyAssignable`. — *end note*]

2

In table 103: `X` is an unordered associative container class, `a` is an object of type `X`, `b` is a possibly const object of type `X`, `a_uniq` is an object of type `X` when `X` supports unique keys, `a_eq` is an object of type `X` when `X` supports equivalent keys, `i` and `j` are input iterators that refer to `value_type`, `[i, j)` is a valid range, `p` and `q2` are valid const iterators to `a`, `q` and `q1` are valid dereferenceable const iterators to `a`, `[q1, q2)` is a valid range in `a`, `il` designates an object of type `initializer_list<value_type>`, `t` is a value of type `X::value_type`, `k` is a value of type `key_type`, `hf` is a possibly const value of type `hasher`, `eq` is a possibly const value of type `key_equal`, `n` is a value of type `size_type`, and `z` is a value of type `float`.

Table 103 — Unordered associative container requirements (in addition to container)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`X::key_type`	`Key`		compile time
`X::mapped_type` (`unordered_map` and `unordered_multimap` only)	`T`		compile time
`X::value_type` (`unordered_set` and `unordered_multiset` only)	`Key`	*Requires:* `value_type` is `Erasable` from `X`	compile time

Table 103 — Unordered associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`X::value_type` (`unordered_map` and `unordered_multimap` only)	`pair<const Key, T>`	*Requires:* `value_type` is `Erasable` from `X`	compile time
`X::hasher`	`Hash`	`Hash` shall be a unary function object type such that the expression `hf(k)` has type `std::size_t`.	compile time
`X::key_equal`	`Pred`	`Pred` shall be a binary predicate that takes two arguments of type `Key`. `Pred` is an equivalence relation.	compile time
`X::local_iterator`	An iterator type whose category, value type, difference type, and pointer and reference types are the same as `X::iterator`'s.	A `local_iterator` object may be used to iterate through a single bucket, but may not be used to iterate across buckets.	compile time
`X::const_local_iterator`	An iterator type whose category, value type, difference type, and pointer and reference types are the same as `X::const_iterator`'s.	A `const_local_iterator` object may be used to iterate through a single bucket, but may not be used to iterate across buckets.	compile time
`X(n, hf, eq)` `X a(n, hf, eq)`	X	*Requires:* `hasher` and `key_equal` are `CopyConstructible`. *Effects:* Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `eq` as the key equality predicate.	$\mathcal{O}(n)$
`X(n, hf)` `X a(n, hf)`	X	*Requires:* `hasher` is `CopyConstructible` and `key_equal` is `DefaultConstructible`. *Effects:* Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `key_equal()` as the key equality predicate.	$\mathcal{O}(n)$

Table 103 — Unordered associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`X(n)` `X a(n)`	X	*Requires:* `hasher` and `key_equal` are `DefaultConstructible`. *Effects:* Constructs an empty container with at least `n` buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate.	$\mathcal{O}(n)$
`X()` `X a`	X	*Requires:* `hasher` and `key_equal` are `DefaultConstructible`. *Effects:* Constructs an empty container with an unspecified number of buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate.	constant
`X(i, j, n, hf, eq)` `X a(i, j, n, hf, eq)`	X	*Requires:* `hasher` and `key_equal` are `CopyConstructible`. `value_type` is `EmplaceConstructible` into `X` from `*i`. *Effects:* Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `eq` as the key equality predicate, and inserts elements from `[i, j)` into it.	Average case $\mathcal{O}(N)$ (N is `distance(i, j)`), worst case $\mathcal{O}(N^2)$
`X(i, j, n, hf)` `X a(i, j, n, hf)`	X	*Requires:* `hasher` is `CopyConstructible` and `key_equal` is `DefaultConstructible`. `value_type` is `EmplaceConstructible` into `X` from `*i`. *Effects:* Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `[i, j)` into it.	Average case $\mathcal{O}(N)$ (N is `distance(i, j)`), worst case $\mathcal{O}(N^2)$

Table 103 — Unordered associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`X(i, j, n)` `X a(i, j, n)`	X	*Requires:* `hasher` and `key_equal` are `DefaultConstructible`. `value_type` is `EmplaceConstructible` into `X` from `*i`. *Effects:* Constructs an empty container with at least `n` buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `[i, j)` into it.	Average case $\mathscr{O}(N)$ (N is `distance(i, j)`), worst case $\mathscr{O}(N^2)$
`X(i, j)` `X a(i, j)`	X	*Requires:* `hasher` and `key_equal` are `DefaultConstructible`. `value_type` is `EmplaceConstructible` into `X` from `*i`. *Effects:* Constructs an empty container with an unspecified number of buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `[i, j)` into it.	Average case $\mathscr{O}(N)$ (N is `distance(i, j)`), worst case $\mathscr{O}(N^2)$
`X(il)`	`X`	Same as `X(il.begin(), il.end())`.	Same as `X(il.begin(), il.end())`.
`X(il, n)`	`X`	Same as `X(il.begin(), il.end(), n)`.	Same as `X(il.begin(), il.end(), n)`.
`X(il, n, hf)`	`X`	Same as `X(il.begin(), il.end(), n, hf)`.	Same as `X(il.begin(), il.end(), n, hf)`.
`X(il, n, hf, eq)`	`X`	Same as `X(il.begin(), il.end(), n, hf, eq)`.	Same as `X(il.begin(), il.end(), n, hf, eq)`.
`X(b)` `X a(b)`	`X`	Copy constructor. In addition to the requirements of Table 96, copies the hash function, predicate, and maximum load factor.	Average case linear in `b.size()`, worst case quadratic.

Table 103 — Unordered associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`a = b`	`X&`	Copy assignment operator. In addition to the requirements of Table 96, copies the hash function, predicate, and maximum load factor.	Average case linear in `b.size()`, worst case quadratic.
`a = il`	`X&`	*Requires:* `value_type` is `CopyInsertable` into `X` and `CopyAssignable`. *Effects:* Assigns the range `[il.begin(),il.end())` into `a`. All existing elements of `a` are either assigned to or destroyed.	Same as `a = X(il)`.
`b.hash_function()`	`hasher`	Returns `b`'s hash function.	constant
`b.key_eq()`	`key_equal`	Returns `b`'s key equality predicate.	constant
`a_uniq. emplace(args)`	`pair<iterator, bool>`	*Requires:* `value_type` shall be `EmplaceConstructible` into `X` from `args`. *Effects:* Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...` if and only if there is no element in the container with key equivalent to the key of `t`. The `bool` component of the returned pair is true if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of `t`.	Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_uniq. size()`).
`a_eq.emplace(args)`	`iterator`	*Requires:* `value_type` shall be `EmplaceConstructible` into `X` from `args`. *Effects:* Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...` and returns the iterator pointing to the newly inserted element.	Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_eq. size()`).

Table 103 — Unordered associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`a.emplace_hint(p, args)`	`iterator`	*Requires:* `value_type` shall be `EmplaceConstructible` into `X` from `args`. *Effects:* Equivalent to `a.emplace( std::forward<Args>(args)...)`. Return value is an iterator pointing to the element with the key equivalent to the newly inserted element. The `const_iterator p` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.	Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a.size()`).
`a_uniq.insert(t)`	`pair<iterator, bool>`	*Requires:* If `t` is a non-const rvalue expression, `value_type` shall be `MoveInsertable` into `X`; otherwise, `value_type` shall be `CopyInsertable` into `X`. *Effects:* Inserts `t` if and only if there is no element in the container with key equivalent to the key of `t`. The `bool` component of the returned pair indicates whether the insertion takes place, and the `iterator` component points to the element with key equivalent to the key of `t`.	Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_uniq.size()`).
`a_eq.insert(t)`	`iterator`	*Requires:* If `t` is a non-const rvalue expression, `value_type` shall be `MoveInsertable` into `X`; otherwise, `value_type` shall be `CopyInsertable` into `X`. *Effects:* Inserts `t`, and returns an iterator pointing to the newly inserted element.	Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_eq.size()`).

Table 103 — Unordered associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`a.insert(q, t)`	`iterator`	*Requires:* If `t` is a non-const rvalue expression, `value_type` shall be `MoveInsertable` into `X`; otherwise, `value_type` shall be `CopyInsertable` into `X`. *Effects:* Equivalent to a.insert(t). Return value is an iterator pointing to the element with the key equivalent to that of `t`. The iterator `q` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.	Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a.size()`).
`a.insert(i, j)`	`void`	*Requires:* `value_type` shall be `EmplaceConstructible` into `X` from `*i`. Pre: `i` and `j` are not iterators in `a`. Equivalent to `a.insert(t)` for each element in `[i,j)`.	Average case $\mathcal{O}(N)$, where N is `distance(i, j)`. Worst case $\mathcal{O}(N *$ `(a.size()) + N`).
`a.insert(il)`	`void`	Same as `a.insert(il.begin(), il.end())`.	Same as `a.insert( il.begin(), il.end())`.
`a.erase(k)`	`size_type`	Erases all elements with key equivalent to `k`. Returns the number of elements erased.	Average case $\mathcal{O}$(`a.count(k)`). Worst case $\mathcal{O}$(`a.size()`).
`a.erase(q)`	`iterator`	Erases the element pointed to by `q`. Return value is the iterator immediately following `q` prior to the erasure.	Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a.size()`).
`a.erase(q1, q2)`	`iterator`	Erases all elements in the range `[q1, q2)`. Return value is the iterator immediately following the erased elements prior to the erasure.	Average case linear in `distance(q1, q2)`, worst case $\mathcal{O}$(`a.size()`).
`a.clear()`	`void`	Erases all elements in the container. Post: `a.empty()` returns `true`	Linear.
`b.find(k)`	`iterator`; `const_iterator` for const `b`.	Returns an iterator pointing to an element with key equivalent to `k`, or `b.end()` if no such element exists.	Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`b.size()`).

Table 103 — Unordered associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`b.count(k)`	`size_type`	Returns the number of elements with key equivalent to `k`.	Average case $\mathcal{O}$(`b.count(k)`), worst case $\mathcal{O}$(`b.size()`).
`b.equal_range(k)`	`pair<iterator, iterator>`; `pair<const_iterator, const_iterator>` for const `b`.	Returns a range containing all elements with keys equivalent to `k`. Returns `make_pair(b.end(), b.end())` if no such elements exist.	Average case $\mathcal{O}$(`b.count(k)`). Worst case $\mathcal{O}$(`b.size()`).
`b.bucket_count()`	`size_type`	Returns the number of buckets that `b` contains.	Constant
`b.max_bucket_count()`	`size_type`	Returns an upper bound on the number of buckets that `b` might ever contain.	Constant
`b.bucket(k)`	`size_type`	Pre: `b.bucket_count() > 0`. Returns the index of the bucket in which elements with keys equivalent to `k` would be found, if any such element existed. Post: the return value shall be in the range `[0, b.bucket_count())`.	Constant
`b.bucket_size(n)`	`size_type`	Pre: `n` shall be in the range `[0, b.bucket_count())`. Returns the number of elements in the `n` th bucket.	$\mathcal{O}$(`b.bucket_size(n)`)
`b.begin(n)`	`local_iterator`; `const_local_iterator` for const `b`.	Pre: `n` shall be in the range `[0, b.bucket_count())`. `b.begin(n)` returns an iterator referring to the first element in the bucket. If the bucket is empty, then `b.begin(n) == b.end(n)`.	Constant
`b.end(n)`	`local_iterator`; `const_local_iterator` for const `b`.	Pre: `n` shall be in the range `[0, b.bucket_count())`. `b.end(n)` returns an iterator which is the past-the-end value for the bucket.	Constant
`b.cbegin(n)`	`const_local_iterator`	Pre: `n` shall be in the range `[0, b.bucket_count())`. Note: `[b.cbegin(n), b.cend(n))` is a valid range containing all of the elements in the `n` th bucket.	Constant
`b.cend(n)`	`const_local_iterator`	Pre: `n` shall be in the range `[0, b.bucket_count())`.	Constant

Table 103 — Unordered associative container requirements (in addition to container) (continued)

Expression	Return type	Assertion/note pre-/post-condition	Complexity
`b.load_factor()`	`float`	Returns the average number of elements per bucket.	Constant
`b.max_load_factor()`	`float`	Returns a positive number that the container attempts to keep the load factor less than or equal to. The container automatically increases the number of buckets as necessary to keep the load factor below this number.	Constant
`a.max_load_-factor(z)`	`void`	Pre: `z` shall be positive. May change the container's maximum load factor, using `z` as a hint.	Constant
`a.rehash(n)`	`void`	Post: `a.bucket_count() > a.size() / a.max_load_factor()` and `a.bucket_count() >= n`.	Average case linear in `a.size()`, worst case quadratic.
`a.reserve(n)`	`void`	Same as `a.rehash(ceil(n / a.max_load_factor()))`.	Average case linear in `a.size()`, worst case quadratic.

1

Two unordered containers `a` and `b` compare equal if `a.size() == b.size()` and, for every equivalent-key group `[Ea1,Ea2)` obtained from `a.equal_range(Ea1)`, there exists an equivalent-key group `[Eb1,Eb2)` obtained from `b.equal_range(Ea1)`, such that `is_permutation(Ea1, Ea2, Eb1, Eb2)` returns `true`. For `unordered_set` and `unordered_map`, the complexity of `operator==` (i.e., the number of calls to the `==` operator of the `value_type`, to the predicate returned by `key_equal()`, and to the hasher returned by `hash_function()`) is proportional to N in the average case and to N^2 in the worst case, where N is a.size(). For `unordered_multiset` and `unordered_multimap`, the complexity of `operator==` is proportional to $\sum E_i^2$ in the average case and to N^2 in the worst case, where N is `a.size()`, and E_i is the size of the ith equivalent-key group in `a`. However, if the respective elements of each corresponding pair of equivalent-key groups Ea_i and Eb_i are arranged in the same order (as is commonly the case, e.g., if `a` and `b` are unmodified copies of the same container), then the average-case complexity for `unordered_multiset` and `unordered_multimap` becomes proportional to N (but worst-case complexity remains $\mathscr{O}(N^2)$, e.g., for a pathologically bad hash function). The behavior of a program that uses `operator==` or `operator!=` on unordered containers is undefined unless the `Hash` and `Pred` function objects respectively have the same behavior for both containers and the equality comparison operator for `Key` is a refinement[263] of the partition into equivalent-key groups produced by `Pred`.

1 The iterator types `iterator` and `const_iterator` of an unordered associative container are of at least the forward iterator category. For unordered associative containers where the key type and value type are the

263) Equality comparison is a refinement of partitioning if no two objects that compare equal fall into different partitions.

same, both `iterator` and `const_iterator` are const iterators.

2

The `insert` and `emplace` members shall not affect the validity of references to container elements, but may invalidate all iterators to the container. The `erase` members shall invalidate only iterators and references to the erased elements, and preserve the relative order of the elements that are not erased.

1

The `insert` and `emplace` members shall not affect the validity of iterators if `(N+n) < z * B`, where `N` is the number of elements in the container prior to the insert operation, `n` is the number of elements inserted, `B` is the container's bucket count, and `z` is the container's maximum load factor.

23.539.0.1 Exception safety guarantees [unord.req.except]

1 For unordered associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container's `Hash` or `Pred` object (if any).

2 For unordered associative containers, if an exception is thrown by any operation other than the container's hash function from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

3 For unordered associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container's Hash or Pred object (if any).

4 For unordered associative containers, if an exception is thrown from within a `rehash()` function other than by the container's hash function or comparison function, the `rehash()` function has no effect.

23.540 Sequence containers [sequences]

23.540.1 In general [sequences.general]

1

The headers `<array>`, `<deque>`, `<forward_list>`, `<list>`, and `<vector>` define template classes that meet the requirements for sequence containers.

1

The headers `<queue>` and `<stack>` define container adaptors (23.939) that also meet the requirements for sequence containers.

Header `<array>` synopsis

```
#include <initializer_list>

namespace std {
  template <class T, size_t N> struct array;
  template <class T, size_t N>
    bool operator==(const array<T,N>& x, const array<T,N>& y);
  template <class T, size_t N>
    bool operator!=(const array<T,N>& x, const array<T,N>& y);
  template <class T, size_t N>
    bool operator<(const array<T,N>& x, const array<T,N>& y);
  template <class T, size_t N>
    bool operator>(const array<T,N>& x, const array<T,N>& y);
  template <class T, size_t N>
    bool operator<=(const array<T,N>& x, const array<T,N>& y);
  template <class T, size_t N>
    bool operator>=(const array<T,N>& x, const array<T,N>& y);
  template <class T, size_t N>
```

```
    void swap(array<T,N>& x, array<T,N>& y) noexcept(noexcept(x.swap(y)));

  template <class T> class tuple_size;
  template <size_t I, class T> class tuple_element;
  template <class T, size_t N>
    struct tuple_size<array<T, N> >;
  template <size_t I, class T, size_t N>
    struct tuple_element<I, array<T, N> >;
  template <size_t I, class T, size_t N>
    constexpr T& get(array<T, N>&) noexcept;
  template <size_t I, class T, size_t N>
    constexpr T&& get(array<T, N>&&) noexcept;
  template <size_t I, class T, size_t N>
    constexpr const T& get(const array<T, N>&) noexcept;
}
```

Header <deque> synopsis

```
#include <initializer_list>

namespace std {
  template <class T, class Allocator = allocator<T> > class deque;
  template <class T, class Allocator>
    bool operator==(const deque<T,Allocator>& x, const deque<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator<(const deque<T,Allocator>& x, const deque<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator!=(const deque<T,Allocator>& x, const deque<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator>(const deque<T,Allocator>& x, const deque<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator>=(const deque<T,Allocator>& x, const deque<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator<=(const deque<T,Allocator>& x, const deque<T,Allocator>& y);
  template <class T, class Allocator>
    void swap(deque<T,Allocator>& x, deque<T,Allocator>& y);
}
```

Header <forward_list> synopsis

```
#include <initializer_list>

namespace std {
  template <class T, class Allocator = allocator<T> > class forward_list;
  template <class T, class Allocator>
    bool operator==(const forward_list<T,Allocator>& x, const forward_list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator< (const forward_list<T,Allocator>& x, const forward_list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator!=(const forward_list<T,Allocator>& x, const forward_list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator> (const forward_list<T,Allocator>& x, const forward_list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator>=(const forward_list<T,Allocator>& x, const forward_list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator<=(const forward_list<T,Allocator>& x, const forward_list<T,Allocator>& y);
```

```
  template <class T, class Allocator>
    void swap(forward_list<T,Allocator>& x, forward_list<T,Allocator>& y);
}
```

Header <list> synopsis

```
#include <initializer_list>

namespace std {
  template <class T, class Allocator = allocator<T> > class list;
  template <class T, class Allocator>
    bool operator==(const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator< (const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator!=(const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator> (const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator>=(const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator<=(const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    void swap(list<T,Allocator>& x, list<T,Allocator>& y);
}
```

Header <vector> synopsis

```
#include <initializer_list>

namespace std {
  template <class T, class Allocator = allocator<T> > class vector;
  template <class T, class Allocator>
    bool operator==(const vector<T,Allocator>& x,const vector<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator< (const vector<T,Allocator>& x,const vector<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator!=(const vector<T,Allocator>& x,const vector<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator> (const vector<T,Allocator>& x,const vector<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator>=(const vector<T,Allocator>& x,const vector<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator<=(const vector<T,Allocator>& x,const vector<T,Allocator>& y);
  template <class T, class Allocator>
    void swap(vector<T,Allocator>& x, vector<T,Allocator>& y);

  template <class Allocator> class vector<bool,Allocator>;

  // hash support
  template <class T> struct hash;
  template <class Allocator> struct hash<vector<bool, Allocator> >;
}
```

23.542.1 Class template array [array]

23.542.1.1 Class template array overview [array.overview]

1

The header `<array>` defines a class template for storing fixed-size sequences of objects. An `array` supports random access iterators. An instance of `array<T, N>` stores `N` elements of type `T`, so that `size() == N` is an invariant. The elements of an `array` are stored contiguously, meaning that if `a` is an `array<T, N>` then it obeys the identity `&a[n] == &a[0] + n` for all `0 <= n < N`.

1

An `array` is an aggregate (8.1817.1) that can be initialized with the syntax

```
array<T, N> a = { initializer-list };
```

where *initializer-list* is a comma-separated list of up to `N` elements whose types are convertible to `T`.

1

An `array` satisfies all of the requirements of a container and of a reversible container (23.2), except that a default constructed `array` object is not empty and that `swap` does not have constant complexity. An `array` satisfies some of the requirements of a sequence container (23.224.1). Descriptions are provided here only for operations on `array` that are not described in one of these tables and for operations where there is additional semantic information.

```
namespace std {
  template <class T, size_t N>
  struct array {
    // types:
    typedef T&                                    reference;
    typedef const T&                              const_reference;
    typedef implementation-defined                iterator;
    typedef implementation-defined                const_iterator;
    typedef size_t                                size_type;
    typedef ptrdiff_t                             difference_type;
    typedef T                                     value_type;
    typedef T*                                    pointer;
    typedef const T*                              const_pointer;
    typedef std::reverse_iterator<iterator>       reverse_iterator;
    typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

    T       elems[N];            // exposition only

    // no explicit construct/copy/destroy for aggregate type

    void fill(const T& u);
    void swap(array&) noexcept(noexcept(swap(declval<T&>(), declval<T&>())));

    // iterators:
    iterator               begin() noexcept;
    const_iterator         begin() const noexcept;
    iterator               end() noexcept;
    const_iterator         end() const noexcept;

    reverse_iterator       rbegin() noexcept;
    const_reverse_iterator rbegin() const noexcept;
    reverse_iterator       rend() noexcept;
    const_reverse_iterator rend() const noexcept;
```

```
    const_iterator         cbegin() const noexcept;
    const_iterator         cend() const noexcept;
    const_reverse_iterator crbegin() const noexcept;
    const_reverse_iterator crend() const noexcept;

    // capacity:
    constexpr size_type size() const noexcept;
    constexpr size_type max_size() const noexcept;
    constexpr bool      empty() const noexcept;

    // element access:
    reference                 operator[](size_type n);
    constexpr const_reference operator[](size_type n) const;
    reference                 at(size_type n);
    constexpr const_reference at(size_type n) const;
    reference                 front();
    constexpr const_reference front() const;
    reference                 back();
    constexpr const_reference back() const;

    T *       data() noexcept;
    const T * data() const noexcept;
  };
}
```

1

[*Note:* The member variable `elems` is shown for exposition only, to emphasize that `array` is a class aggregate. The name `elems` is not part of `array`'s interface. — *end note*]

23.579.0.1 `array` constructors, copy, and assignment [array.cons]

1

The conditions for an aggregate (8.1817.1) shall be met. Class `array` relies on the implicitly-declared special member functions (12.30, 12.807, and 12.1577) to conform to the container requirements table in 23.2. In addition to the requirements specified in the container requirements table, the implicit move constructor and move assignment operator for `array` require that `T` be `MoveConstructible` or `MoveAssignable`, respectively.

23.581.0.1 `array` specialized algorithms [array.special]

```
template <class T, size_t N> void swap(array<T,N>& x, array<T,N>& y) noexcept(noexcept(x.swap(y)));
```

1 *Effects:*

```
x.swap(y);
```

2 *Complexity:* Linear in `N`.

23.581.0.2 `array::size` [array.size]

```
template <class T, size_t N> constexpr size_type array<T,N>::size() const noexcept;
```

1 *Returns:* `N`

23.581.0.3 `array::data` [array.data]

```
T* data() noexcept;
const T* data() const noexcept;
```

1 *Returns:* `elems`.

23.581.0.4 `array::fill` [array.fill]

```
void fill(const T& u);
```

1 *Effects:* `fill_n(begin(), N, u)`

23.581.0.5 `array::swap` [array.swap]

```
void swap(array& y) noexcept(noexcept(swap(declval<T&>(), declval<T&>())));
```

1 *Effects:* `swap_ranges(begin(), end(), y.begin())`

2 *Throws:* Nothing unless one of the element-wise swap calls throws an exception.

3 *Note:* Unlike the `swap` function for other containers, `array::swap` takes linear time, may exit via an exception, and does not cause iterators to become associated with the other container.

23.581.0.6 Zero sized arrays [array.zero]

1 `array` shall provide support for the special case `N == 0`.

1 In the case that `N == 0`, `begin() == end() ==` unique value. The return value of `data()` is unspecified.

1

The effect of calling `front()` or `back()` for a zero-sized array is undefined.

1

Member function `swap()` shall have a *noexcept-specification* which is equivalent to `noexcept(true)`.

23.586.0.1 Tuple interface to class template `array` [array.tuple]

```
template <class T, size_t N>
struct tuple_size<array<T, N>>
  : integral_constant<size_t, N> { };
```

```
tuple_element<I, array<T, N> >::type
```

1 *Requires:* `I < N`. The program is ill-formed if `I` is out of bounds.

2

Value: The type T.

```
template <size_t I, class T, size_t N>
constexpr T& get(array<T, N>& a) noexcept;
```

1 *Requires:* `I < N`. The program is ill-formed if `I` is out of bounds.

2 *Returns:* A reference to the `I`th element of `a`, where indexing is zero-based.

```
template <size_t I, class T, size_t N>
constexpr T&& get(array<T, N>&& a) noexcept;
```

3 *Effects:* Equivalent to `return std::move(get<I>(a));`

```
template <size_t I, class T, size_t N>
constexpr const T& get(const array<T, N>& a) noexcept;
```

4 *Requires:* `I < N`. The program is ill-formed if `I` is out of bounds.

5 *Returns:* A const reference to the `I`th element of `a`, where indexing is zero-based.

23.588.1 Class template deque [deque]

23.588.1.1 Class template deque overview [deque.overview]

1

A deque is a sequence container that, like a vector (23.696.1), supports random access iterators. In addition, it supports constant time insert and erase operations at the beginning or the end; insert and erase in the middle take linear time. That is, a deque is especially optimized for pushing and popping elements at the beginning and end. As with vectors, storage management is handled automatically.

1 A deque satisfies all of the requirements of a container, of a reversible container (given in tables in 23.2), of a sequence container, including the optional sequence container requirements (23.224.1), and of an allocator-aware container (Table 99). Descriptions are provided here only for operations on deque that are not described in one of these tables or for operations where there is additional semantic information.

```
namespace std {
  template <class T, class Allocator = allocator<T> >
  class deque {
  public:
    // types:
    typedef value_type&                          reference;
    typedef const value_type&                    const_reference;
    typedef implementation-defined               iterator;       // See 23.2
    typedef implementation-defined               const_iterator; // See 23.2
    typedef implementation-defined               size_type;      // See 23.2
    typedef implementation-defined               difference_type;// See 23.2
    typedef T                                    value_type;
    typedef Allocator                            allocator_type;
    typedef typename allocator_traits<Allocator>::pointer          pointer;
    typedef typename allocator_traits<Allocator>::const_pointer    const_pointer;
    typedef std::reverse_iterator<iterator>      reverse_iterator;
    typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

    // 23.592.0.1, construct/copy/destroy:
    deque() : deque(Allocator()) { }

  // specialized algorithms:
  template <class T, class Allocator>
    void swap(deque<T,Allocator>& x, deque<T,Allocator>& y);
}
```

23.592.0.1 `deque` constructors, copy, and assignment [deque.cons]

`explicit deque(const Allocator&);`

1

Effects: Constructs an empty `deque`, using the specified allocator.

1 *Complexity:* Constant.

`explicit deque(size_type n, const Allocator& = Allocator());`

2 *Effects:* Constructs a `deque` with `n` default-inserted elements using the specified allocator.

3 *Requires:* `T` shall be `DefaultInsertable` into `*this`.

4 *Complexity:* Linear in `n`.

```
deque(size_type n, const T& value,
      const Allocator& = Allocator());
```

5

Effects: Constructs a `deque` with `n` copies of `value`, using the specified allocator.

1 *Requires:* `T` shall be `CopyInsertable` into `*this`.

2

Complexity: Linear in `n`.

```
template <class InputIterator>
  deque(InputIterator first, InputIterator last,
        const Allocator& = Allocator());
```

1 *Effects:* Constructs a `deque` equal to the range `[first,last)`, using the specified allocator.

2 *Complexity:* Linear in `distance(first, last)`.

23.597.0.1 deque capacity [deque.capacity]

```
void resize(size_type sz);
```

1

Effects: If `sz <= size()`, equivalent to calling `pop_back() size() - sz` times. If `size() < sz`, appends `sz - size()` default-inserted elements to the sequence.

1 *Requires:* `T` shall be `MoveInsertable` and `DefaultInsertable` into `*this`.

```
void resize(size_type sz, const T& c);
```

2 *Effects:* If `sz <= size()`, equivalent to calling `pop_back() size() - sz` times. If `size() < sz`, appends `sz - size()` copies of `c` to the sequence.

3 *Requires:* `T` shall be `CopyInsertable` into `*this`.

```
void shrink_to_fit();
```

4 *Requires:* `T` shall be `MoveInsertable` into `*this`.

5 *Complexity:* Linear in the size of the sequence.

6 *Remarks:* `shrink_to_fit` is a non-binding request to reduce memory use but does not change the size of the sequence. [*Note:* The request is non-binding to allow latitude for implementation-specific optimizations. — *end note*]

23.610.0.1 deque modifiers [deque.modifiers]

```
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template <class InputIterator>
  iterator insert(const_iterator position,
                  InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);

template <class... Args> void emplace_front(Args&&... args);
template <class... Args> void emplace_back(Args&&... args);
template <class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);
```

1

Effects: An insertion in the middle of the deque invalidates all the iterators and references to elements of the deque. An insertion at either end of the deque invalidates all the iterators to the deque, but has no effect on the validity of references to elements of the deque.

1

Remarks: If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of `T` there are no effects. If an exception is thrown while inserting a single element at either end, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-`CopyInsertable` `T`, the effects are unspecified.

1

Complexity: The complexity is linear in the number of elements inserted plus the lesser of the distances to the beginning and end of the deque. Inserting a single element either at the beginning or end of a deque always takes constant time and causes a single call to a constructor of `T`.

```
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
```

1

Effects: An erase operation that erases the last element of a deque invalidates only the past-the-end iterator and all iterators and references to the erased elements. An erase operation that erases the first element of a deque but not the last element invalidates only the erased elements. An erase operation that erases neither the first element nor the last element of a deque invalidates the past-the-end iterator and all iterators and references to all the elements of the deque.

1

Complexity: The number of calls to the destructor is the same as the number of elements erased, but the number of calls to the assignment operator is no more than the lesser of the number of elements before the erased elements and the number of elements after the erased elements.

1

Throws: Nothing unless an exception is thrown by the copy constructor, move constructor, assignment operator, or move assignment operator of `T`.

23.652.0.1 `deque` specialized algorithms [deque.special]

```
template <class T, class Allocator>
  void swap(deque<T,Allocator>& x, deque<T,Allocator>& y);
```

1 *Effects:*

```
x.swap(y);
```

23.652.1 Class template `forward_list` [forwardlist]

23.652.1.1 Class template `forward_list` overview [forwardlist.overview]

1

A `forward_list` is a container that supports forward iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Fast random access to list elements is not supported. [*Note:* It is intended that `forward_list` have zero space or time overhead relative to a hand-written C-style singly linked list. Features that would conflict with that goal have been omitted. — *end note*]

1

A `forward_list` satisfies all of the requirements of a container (Table 96), except that the `size()` member function is not provided and `operator==` has linear complexity. A `forward_list` also satisfies all of the requirements for an allocator-aware container (Table 99). In addition, a `forward_list` provides the `assign` member functions (Table 100) and several of the optional container requirements (Table 101). Descriptions are provided here only for operations on `forward_list` that are not described in that table or for operations where there is additional semantic information.

1 [*Note:* Modifying any list requires access to the element preceding the first element of interest, but in a `forward_list` there is no constant-time way to access a preceding element. For this reason, ranges that are modified, such as those supplied to `erase` and `splice`, must be open at the beginning. — *end note*]

```
namespace std {
  template <class T, class Allocator = allocator<T> >
  class forward_list {
  public:
    // types:

}
```

23.655.0.1 `forward_list` constructors, copy, assignment [forwardlist.cons]

`explicit forward_list(const Allocator&);`

1 *Effects:* Constructs an empty `forward_list` object using the specified allocator.

2 *Complexity:* Constant.

`explicit forward_list(size_type n, const Allocator& = Allocator());`

3 *Effects:* Constructs a `forward_list` object with `n` default-inserted elements using the specified allocator.

4 *Requires:* `T` shall be `DefaultInsertable` into `*this`.

5 *Complexity:* Linear in `n`.

`forward_list(size_type n, const T& value, const Allocator& = Allocator());`

6 *Effects:* Constructs a `forward_list` object with `n` copies of `value` using the specified allocator.

7 *Requires:* `T` shall be `CopyInsertable` into `*this`.

8 *Complexity:* Linear in `n`.

```
template <class InputIterator>
  forward_list(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

9 *Effects:* Constructs a `forward_list` object equal to the range `[first,last)`.

10 *Complexity:* Linear in `distance(first, last)`.

23.655.0.2 `forward_list` iterators [forwardlist.iter]

```
iterator before_begin() noexcept;
const_iterator before_begin() const noexcept;
const_iterator cbefore_begin() const noexcept;
```

1

Returns: A non-dereferenceable iterator that, when incremented, is equal to the iterator returned by `begin()`.

1 *Effects:* `cbefore_begin()` is equivalent to `const_cast<forward_list const&>(*this).before_begin()`.

2 *Remarks:* `before_begin() == end()` shall equal `false`.

23.656.0.1 `forward_list` element access [forwardlist.access]

```
reference front();
const_reference front() const;
```

1 *Returns:* `*begin()`

23.656.0.2 `forward_list` modifiers [forwardlist.modifiers]

1

None of the overloads of `insert_after` shall affect the validity of iterators and references, and `erase_after` shall invalidate only iterators and references to the erased elements. If an exception is thrown during `insert_after` there shall be no effect. Inserting `n` elements into a `forward_list` is linear in `n`, and the number of calls to the copy or move constructor of `T` is exactly equal to `n`. Erasing `n` elements from a `forward_list` is linear in `n` and the number of calls to the destructor of type `T` is exactly equal to `n`.

```
template <class... Args> void emplace_front(Args&&... args);
```

1 *Effects:* Inserts an object of type `value_type` constructed with `value_type(std::forward<Args>(args)...)` at the beginning of the list.

```
void push_front(const T& x);
void push_front(T&& x);
```

2 *Effects:* Inserts a copy of `x` at the beginning of the list.

```
void pop_front();
```

3 *Effects:* `erase_after(before_begin())`

```
iterator insert_after(const_iterator position, const T& x);
iterator insert_after(const_iterator position, T&& x);
```

4 *Requires:* `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(),end())`.

5 *Effects:* Inserts a copy of `x` after `position`.

6

Returns: An iterator pointing to the copy of `x`.

```
iterator insert_after(const_iterator position, size_type n, const T& x);
```

1 *Requires:* `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(),end())`.

2 *Effects:* Inserts `n` copies of `x` after `position`.

3

Returns: An iterator pointing to the last inserted copy of `x` or `position` if `n == 0`.

```
template <class InputIterator>
  iterator insert_after(const_iterator position, InputIterator first, InputIterator last);
```

1 *Requires:* `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(),end())`. `first` and `last` are not iterators in `*this`.

2 *Effects:* Inserts copies of elements in `[first,last)` after `position`.

3 *Returns:* An iterator pointing to the last inserted element or `position` if `first == last`.

```
iterator insert_after(const_iterator position, initializer_list<T> il);
```

4 *Effects:* `insert_after(p, il.begin(), il.end())`.

5 *Returns:* An iterator pointing to the last inserted element or `position` if `il` is empty.

```
template <class... Args>
  iterator emplace_after(const_iterator position, Args&&... args);
```

1 *Requires:* `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(),end())`.

2 *Effects:* Inserts an object of type `value_type` constructed with `value_type(std::forward<Args>(args)...)` after `position`.

3 *Returns:* An iterator pointing to the new object.

```
iterator erase_after(const_iterator position);
```

4 *Requires:* The iterator following `position` is dereferenceable.

5 *Effects:* Erases the element pointed to by the iterator following `position`.

6 *Returns:* An iterator pointing to the element following the one that was erased, or `end()` if no such element exists.

7 *Throws:* Nothing.

```
iterator erase_after(const_iterator position, const_iterator last);
```

8 *Requires:* All iterators in the range `(position,last)` are dereferenceable.

9 *Effects:* Erases the elements in the range `(position,last)`.

10 *Returns:* `last`.

11 *Throws:* Nothing.

```
void resize(size_type sz);
```

12 *Effects:* If `sz < distance(begin(), end())`, erases the last `distance(begin(), end()) - sz` elements from the list. Otherwise, inserts `sz - distance(begin(), end())` default-inserted elements at the end of the list.

13 *Requires:* `T` shall be `DefaultInsertable` into `*this`.

```
void resize(size_type sz, const value_type& c);
```

14 *Effects:* If `sz < distance(begin(), end())`, erases the last `distance(begin(), end()) - sz` elements from the list. Otherwise, inserts `sz - distance(begin(), end())` elements at the end of the list such that each new element, `e`, is initialized by a method equivalent to calling `allocator_traits<allocator_type>::construct(get_allocator(), std::addressof(e), c)`.

1 *Requires:* `T` shall be `CopyInsertable` into `*this`.

```
void clear() noexcept;
```

2 *Effects:* Erases all elements in the range `[begin(),end())`.

3 *Remarks:* Does not invalidate past-the-end iterators.

23.662.0.1 `forward_list` operations [forwardlist.ops]

```
void splice_after(const_iterator position, forward_list& x);
void splice_after(const_iterator position, forward_list&& x);
```

1 *Requires:* `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(),end())`. `get_allocator() == x.get_allocator()`. `&x != this`.

2 *Effects:* Inserts the contents of `x` after `position`, and `x` becomes empty. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

1 *Throws:* Nothing.

2 *Complexity:* $\mathcal{O}(distance(x.begin(), x.end()))$

```
void splice_after(const_iterator position, forward_list& x, const_iterator i);
void splice_after(const_iterator position, forward_list&& x, const_iterator i);
```

3 *Requires:* `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(),end())`. The iterator following `i` is a dereferenceable iterator in `x`. `get_allocator() == x.get_allocator()`.

4 *Effects:* Inserts the element following `i` into `*this`, following `position`, and removes it from `x`. The result is unchanged if `position == i` or `position == ++i`. Pointers and references to `*++i` continue to refer to the same element but as a member of `*this`. Iterators to `*++i` continue to refer to the same element, but now behave as iterators into `*this`, not into `x`.

5 *Throws:* Nothing.

6 *Complexity:* $\mathcal{O}(1)$

```
void splice_after(const_iterator position, forward_list& x,
                  const_iterator first, const_iterator last);
void splice_after(const_iterator position, forward_list&& x,
                  const_iterator first, const_iterator last);
```

7 *Requires:* `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(),end())`. `(first,last)` is a valid range in `x`, and all iterators in the range `(first,last)` are dereferenceable. `position` is not an iterator in the range `(first,last)`. `get_allocator() == x.get_allocator()`.

8 *Effects:* Inserts elements in the range `(first,last)` after `position` and removes the elements from `x`. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

9 *Complexity:* $\mathcal{O}(distance(first, last))$

```
void remove(const T& value);
template <class Predicate> void remove_if(Predicate pred);
```

10 *Effects:* Erases all the elements in the list referred by a list iterator `i` for which the following conditions hold: `*i == value` (for `remove()`), `pred(*i)` is true (for `remove_if()`). Invalidates only the iterators and references to the erased elements.

1 *Throws:* Nothing unless an exception is thrown by the equality comparison or the predicate.

1 *Remarks:* Stable (17.602.0.1).

2

Complexity: Exactly `distance(begin(), end())` applications of the corresponding predicate.

```
void unique();
template <class BinaryPredicate> void unique(BinaryPredicate pred);
```

1 *Effects:* Erases all but the first element from every consecutive group of equal elements referred to by the iterator `i` in the range `[first + 1,last)` for which `*i == *(i-1)` (for the version with no arguments) or `pred(*i, *(i - 1))` (for the version with a predicate argument) holds. Invalidates only the iterators and references to the erased elements.

2 *Throws:* Nothing unless an exception is thrown by the equality comparison or the predicate.

3 *Complexity:* If the range `[first,last)` is not empty, exactly `(last - first) - 1` applications of the corresponding predicate, otherwise no applications of the predicate.

```
void merge(forward_list& x);
void merge(forward_list&& x);
template <class Compare> void merge(forward_list& x, Compare comp);
template <class Compare> void merge(forward_list&& x, Compare comp);
```

4 *Requires:* `comp` defines a strict weak ordering (25.98), and `*this` and `x` are both sorted according to this ordering. `get_allocator() == x.get_allocator()`.

5 *Effects:* Merges the two sorted ranges `[begin(), end())` and `[x.begin(), x.end())`. `x` is empty after the merge. If an exception is thrown other than by a comparison there are no effects. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

6 *Remarks:* Stable (17.602.0.1). The behavior is undefined if `this->get_allocator() != x.get_allocator()`.

7 *Complexity:* At most `distance(begin(), end()) + distance(x.begin(), x.end()) - 1` comparisons.

```
void sort();
template <class Compare> void sort(Compare comp);
```

8 *Requires:* `operator<` (for the version with no arguments) or `comp` (for the version with a comparison argument) defines a strict weak ordering (25.98).

9

Effects: Sorts the list according to the `operator<` or the `comp` function object. If an exception is thrown the order of the elements in `*this` is unspecified. Does not affect the validity of iterators and references.

1 *Remarks:* Stable (17.602.0.1).

2

Complexity: Approximately $N \log N$ comparisons, where N is `distance(begin(), end())`.

```
void reverse() noexcept;
```

1 *Effects:* Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

2 *Complexity:* Linear time.

23.672.0.1 `forward_list` specialized algorithms [forwardlist.spec]

```
template <class T, class Allocator>
  void swap(forward_list<T,Allocator>& x, forward_list<T,Allocator>& y);
```

1 *Effects:* `x.swap(y)`

23.672.1 Class template `list` [list]

23.672.1.1 Class template `list` overview [list.overview]

1

A `list` is a sequence container that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Unlike vectors (23.696.1) and deques (23.588.1), fast random access to list elements is not supported, but many algorithms only need sequential access anyway.

1

A `list` satisfies all of the requirements of a container, of a reversible container (given in two tables in 23.2), of a sequence container, including most of the optional sequence container requirements (23.224.1), and of an allocator-aware container (Table 99). The exceptions are the `operator[]` and `at` member functions, which are not provided.[264] Descriptions are provided here only for operations on `list` that are not described in one of these tables or for operations where there is additional semantic information.

```
namespace std {
  template <class T, class Allocator = allocator<T> >
  class list {
  public:
    // types:
    typedef value_type&                                                reference;
    typedef const value_type&                                          const_reference;
    typedef implementation-defined                iterator;       // see 23.2
    typedef implementation-defined                const_iterator; // see 23.2
    typedef implementation-defined                size_type;      // see 23.2
    typedef implementation-defined                difference_type;// see 23.2
    typedef T                                     value_type;
    typedef Allocator                             allocator_type;
    typedef typename allocator_traits<Allocator>::pointer           pointer;
    typedef typename allocator_traits<Allocator>::const_pointer     const_pointer;
    typedef std::reverse_iterator<iterator>       reverse_iterator;
    typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

    // 23.678.0.1, construct/copy/destroy:
    list() : list(Allocator()) { }
    explicit list(const Allocator&);
    explicit list(size_type n, const Allocator& = Allocator());
    list(size_type n, const T& value, const Allocator& = Allocator());
    template <class InputIterator>
      list(InputIterator first, InputIterator last, const Allocator& = Allocator());
    list(const list& x);
    list(list&& x);
    list(const list&, const Allocator&);
    list(list&&, const Allocator&);
    list(initializer_list<T>, const Allocator& = Allocator());
   ~list();
```

264) These member functions are only provided by containers whose iterators are random access iterators.

```
list& operator=(const list& x);
list& operator=(list&& x);
list& operator=(initializer_list<T>);
template <class InputIterator>
  void assign(InputIterator first, InputIterator last);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

// iterators:
iterator               begin() noexcept;
const_iterator         begin() const noexcept;
iterator               end() noexcept;
const_iterator         end() const noexcept;
reverse_iterator       rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator       rend() noexcept;
const_reverse_iterator rend() const noexcept;

const_iterator         cbegin() const noexcept;
const_iterator         cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// 23.678.0.2, capacity:
bool      empty() const noexcept;

iterator insert(const_iterator position, size_type n, const T& x);
template <class InputIterator>
  iterator insert(const_iterator position, InputIterator first,
                  InputIterator last);
iterator insert(const_iterator position, initializer_list<T> il);
```

```
    iterator erase(const_iterator position);
    iterator erase(const_iterator position, const_iterator last);
    void     swap(list&);
    void     clear() noexcept;

    // 23.682.0.1, list operations:
    void splice(const_iterator position, list& x);
    void splice(const_iterator position, list&& x);
    void splice(const_iterator position, list& x, const_iterator i);
    void splice(const_iterator position, list&& x, const_iterator i);
    void splice(const_iterator position, list& x,
                const_iterator first, const_iterator last);
    void splice(const_iterator position, list&& x,
                const_iterator first, const_iterator last);

    void remove(const T& value);
    template <class Predicate> void remove_if(Predicate pred);

    void unique();
    template <class BinaryPredicate>
      void unique(BinaryPredicate binary_pred);

    void merge(list& x);
    void merge(list&& x);
    template <class Compare> void merge(list& x, Compare comp);
    template <class Compare> void merge(list&& x, Compare comp);

    void sort();
    template <class Compare> void sort(Compare comp);

    void reverse() noexcept;
  };

  template <class T, class Allocator>
    bool operator==(const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator< (const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator!=(const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator> (const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator>=(const list<T,Allocator>& x, const list<T,Allocator>& y);
  template <class T, class Allocator>
    bool operator<=(const list<T,Allocator>& x, const list<T,Allocator>& y);

  // specialized algorithms:
  template <class T, class Allocator>
    void swap(list<T,Allocator>& x, list<T,Allocator>& y);
}
```

23.678.0.1 `list` constructors, copy, and assignment [list.cons]

```
explicit list(const Allocator&);
```

1 *Effects:* Constructs an empty list, using the specified allocator.

2 *Complexity:* Constant.

```
explicit list(size_type n, const Allocator& = Allocator());
```

3 *Effects:* Constructs a `list` with `n` default-inserted elements using the specified allocator.

4 *Requires:* `T` shall be `DefaultInsertable` into `*this`.

5 *Complexity:* Linear in `n`.

```
list(size_type n, const T& value,
     const Allocator& = Allocator());
```

6 *Effects:* Constructs a `list` with `n` copies of `value`, using the specified allocator.

7 *Requires:* `T` shall be `CopyInsertable` into `*this`.

8 *Complexity:* Linear in `n`.

```
template <class InputIterator>
list(InputIterator first, InputIterator last,
     const Allocator& = Allocator());
```

9 *Effects:* Constructs a `list` equal to the range `[first,last)`.

10 *Complexity:* Linear in `distance(first, last)`.

23.678.0.2 `list` capacity [list.capacity]

```
void resize(size_type sz);
```

1

Effects: If `size() < sz`, appends `sz - size()` default-inserted elements to the sequence. If `sz <= size()`, equivalent to

```
list<T>::iterator it = begin();
advance(it, sz);
erase(it, end());
```

1 *Requires:* `T` shall be `DefaultInsertable` into `*this`.

```
void resize(size_type sz, const T& c);
```

2 *Effects:*

```
if (sz > size())
  insert(end(), sz-size(), c);
else if (sz < size()) {
  iterator i = begin();
  advance(i, sz);
  erase(i, end());
}
else
  ;                    // do nothing
```

3 *Requires:* `T` shall be `CopyInsertable` into `*this`.

23.681.0.1 `list` modifiers [list.modifiers]

```
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template <class InputIterator>
  iterator insert(const_iterator position, InputIterator first,
                  InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);

template <class... Args> void emplace_front(Args&&... args);
template <class... Args> void emplace_back(Args&&... args);
template <class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);
```

1 *Remarks:* Does not affect the validity of iterators and references. If an exception is thrown there are no effects.

2

Complexity: Insertion of a single element into a list takes constant time and exactly one call to a constructor of `T`. Insertion of multiple elements into a list is linear in the number of elements inserted, and the number of calls to the copy constructor or move constructor of `T` is exactly equal to the number of elements inserted.

```
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);

void pop_front();
void pop_back();
void clear() noexcept;
```

1 *Effects:* Invalidates only the iterators and references to the erased elements.

2 *Throws:* Nothing.

3 *Complexity:* Erasing a single element is a constant time operation with a single call to the destructor of `T`. Erasing a range in a list is linear time in the size of the range and the number of calls to the destructor of type `T` is exactly equal to the size of the range.

23.682.0.1 `list` operations [list.ops]

1 Since lists allow fast insertion and erasing from the middle of a list, certain operations are provided specifically for them.[265]

2

`list` provides three splice operations that destructively move elements from one list to another. The behavior of splice operations is undefined if `get_allocator() != x.get_allocator()`.

```
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);
```

1 *Requires:* `&x != this`.

2

265) As specified in 17.165.0.1, the requirements in this Clause apply only to lists whose allocators compare equal.

Effects: Inserts the contents of `x` before `position` and `x` becomes empty. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

1 *Throws:* Nothing.

2 *Complexity:* Constant time.

```
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);
```

1 *Effects:* Inserts an element pointed to by `i` from list `x` before `position` and removes the element from `x`. The result is unchanged if `position == i` or `position == ++i`. Pointers and references to `*i` continue to refer to this same element but as a member of `*this`. Iterators to `*i` (including `i` itself) continue to refer to the same element, but now behave as iterators into `*this`, not into `x`.

1 *Requires:* `i` is a valid dereferenceable iterator of `x`.

2 *Throws:* Nothing.

3 *Complexity:* Constant time.

```
void splice(const_iterator position, list& x, const_iterator first,
            const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first,
            const_iterator last);
```

4 *Effects:* Inserts elements in the range `[first,last)` before `position` and removes the elements from `x`.

5 *Requires:* `[first, last)` is a valid range in `x`. The result is undefined if `position` is an iterator in the range `[first,last)`. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

1 *Throws:* Nothing.

2 *Complexity:* Constant time if `&x == this`; otherwise, linear time.

```
                           void remove(const T& value);
template <class Predicate> void remove_if(Predicate pred);
```

1 *Effects:* Erases all the elements in the list referred by a list iterator `i` for which the following conditions hold: `*i == value, pred(*i) != false`. Invalidates only the iterators and references to the erased elements.

1 *Throws:* Nothing unless an exception is thrown by `*i == value` or `pred(*i) != false`.

2 *Remarks:* Stable (17.602.0.1).

3 *Complexity:* Exactly `size()` applications of the corresponding predicate.

```
                                 void unique();
template <class BinaryPredicate> void unique(BinaryPredicate binary_pred);
```

4 *Effects:* Erases all but the first element from every consecutive group of equal elements referred to by the iterator `i` in the range `[first + 1,last)` for which `*i == *(i-1)` (for the version of `unique` with no arguments) or `pred(*i, *(i - 1))` (for the version of `unique` with a predicate argument) holds. Invalidates only the iterators and references to the erased elements.

5 *Throws:* Nothing unless an exception is thrown by `*i == *(i-1)` or `pred(*i, *(i - 1))`

6 *Complexity:* If the range `[first, last)` is not empty, exactly `(last - first) - 1` applications of the corresponding predicate, otherwise no applications of the predicate.

```
void                          merge(list& x);
void                          merge(list&& x);
template <class Compare> void merge(list& x, Compare comp);
template <class Compare> void merge(list&& x, Compare comp);
```

1 *Requires:* `comp` shall define a strict weak ordering (25.98), and both the list and the argument list shall be sorted according to this ordering.

1 *Effects:* If `(&x == this)` does nothing; otherwise, merges the two sorted ranges `[begin(), end())` and `[x.begin(), x.end())`. The result is a range in which the elements will be sorted in non-decreasing order according to the ordering defined by `comp`; that is, for every iterator `i`, in the range other than the first, the condition `comp(*i, *(i - 1))` will be false. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

2 *Remarks:* Stable (17.602.0.1). If `(&x != this)` the range `[x.begin(), x.end())` is empty after the merge. No elements are copied by this operation. The behavior is undefined if `this->get_allocator() != x.get_allocator()`.

3 *Complexity:* At most `size() + x.size() - 1` applications of `comp` if `(&x != this)`; otherwise, no applications of `comp` are performed. If an exception is thrown other than by a comparison there are no effects.

```
void reverse() noexcept;
```

4 *Effects:* Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

5 *Complexity:* Linear time.

```
                          void sort();
template <class Compare> void sort(Compare comp);
```

6 *Requires:* `operator<` (for the first version) or `comp` (for the second version) shall define a strict weak ordering (25.98).

7 *Effects:* Sorts the list according to the `operator<` or a `Compare` function object. Does not affect the validity of iterators and references.

1 *Remarks:* Stable (17.602.0.1).

2 *Complexity:* Approximately $N \log(N)$ comparisons, where `N == size()`.

23.696.0.1 `list` specialized algorithms [list.special]

```
template <class T, class Allocator>
  void swap(list<T,Allocator>& x, list<T,Allocator>& y);
```

1 *Effects:*

```
x.swap(y);
```

23.696.1 Class template `vector` [vector]

23.696.1.1 Class template `vector` overview [vector.overview]

1

A `vector` is a sequence container that supports random access iterators. In addition, it supports (amortized) constant time insert and erase operations at the end; insert and erase in the middle take linear time. Storage management is handled automatically, though hints can be given to improve efficiency. The elements of a vector are stored contiguously, meaning that if `v` is a `vector<T, Allocator>` where `T` is some type other than `bool`, then it obeys the identity `&v[n] == &v[0] + n` for all `0 <= n < v.size()`.

1

A `vector` satisfies all of the requirements of a container and of a reversible container (given in two tables in 23.2), of a sequence container, including most of the optional sequence container requirements (23.224.1), and of an allocator-aware container (Table 99). The exceptions are the `push_front`, `pop_front`, and `emplace_front` member functions, which are not provided. Descriptions are provided here only for operations on `vector` that are not described in one of these tables or for operations where there is additional semantic information.

```
namespace std {
  template <class T, class Allocator = allocator<T> >
  class vector {
  public:
    // types:
    typedef value_type&                          reference;
    typedef const value_type&                    const_reference;
    typedef implementation-defined               iterator;       // see 23.2
    typedef implementation-defined               const_iterator; // see 23.2
    typedef implementation-defined               size_type;      // see 23.2
    typedef implementation-defined               difference_type;// see 23.2
    typedef T                                    value_type;
    typedef Allocator                            allocator_type;
    typedef typename allocator_traits<Allocator>::pointer           pointer;
    typedef typename allocator_traits<Allocator>::const_pointer     const_pointer;
    typedef std::reverse_iterator<iterator>      reverse_iterator;
    typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

    // 23.748.0.1, construct/copy/destroy:
    vector() : vector(Allocator()) { }
    explicit vector(const Allocator&);
    explicit vector(size_type n, const Allocator& = Allocator());
    vector(size_type n, const T& value, const Allocator& = Allocator());

}
```

23.748.0.1 `vector` constructors, copy, and assignment [vector.cons]

`explicit vector(const Allocator&);`

1 *Effects:* Constructs an empty `vector`, using the specified allocator.

2 *Complexity:* Constant.

`explicit vector(size_type n, const Allocator& = Allocator());`

1 *Effects:* Constructs a `vector` with `n` default-inserted elements using the specified allocator.

1 *Requires:* `T` shall be `DefaultInsertable` into `*this`.

2 *Complexity:* Linear in `n`.

```
vector(size_type n, const T& value,
       const Allocator& = Allocator());
```

3 *Effects:* Constructs a `vector` with `n` copies of `value`, using the specified allocator.

4 *Requires:* `T` shall be `CopyInsertable` into `*this`.

5 *Complexity:* Linear in `n`.

```
template <class InputIterator>
  vector(InputIterator first, InputIterator last,
         const Allocator& = Allocator());
```

6

Effects: Constructs a `vector` equal to the range `[first,last)`, using the specified allocator.

1

Complexity: Makes only N calls to the copy constructor of `T` (where N is the distance between `first` and `last`) and no reallocations if iterators first and last are of forward, bidirectional, or random access categories. It makes order `N` calls to the copy constructor of `T` and order $\log(N)$ reallocations if they are just input iterators.

23.758.0.1 `vector` capacity [vector.capacity]

```
size_type capacity() const noexcept;
```

1

Returns: The total number of elements that the vector can hold without requiring reallocation.

```
void reserve(size_type n);
```

1 *Requires:* `T` shall be `MoveInsertable` into `*this`.

2

Effects: A directive that informs a `vector` of a planned change in size, so that it can manage the storage allocation accordingly. After `reserve()`, `capacity()` is greater or equal to the argument of `reserve` if reallocation happens; and equal to the previous value of `capacity()` otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of `reserve()`. If an exception is thrown other than by the move constructor of a non-`CopyInsertable` type, there are no effects.

1

Complexity: It does not change the size of the sequence and takes at most linear time in the size of the sequence.

1

Throws: `length_error` if `n > max_size()`.[266]

1

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence. No reallocation shall take place during insertions that happen after a call to `reserve()` until the time when an insertion would make the size of the vector greater than the value of `capacity()`.

```
void shrink_to_fit();
```

1 *Requires:* `T` shall be `MoveInsertable` into `*this`.

2 *Complexity:* Linear in the size of the sequence.

3

Remarks: `shrink_to_fit` is a non-binding request to reduce `capacity()` to `size()`. [*Note:* The request is non-binding to allow latitude for implementation-specific optimizations. — *end note*] If an exception is thrown other than by the move constructor of a non-`CopyInsertable` `T` there are no effects.

266) `reserve()` uses `Allocator::allocate()` which may throw an appropriate exception.

```
void swap(vector& x);
```

1 *Effects:* Exchanges the contents and `capacity()` of `*this` with that of `x`.

2 *Complexity:* Constant time.

```
void resize(size_type sz);
```

3 *Effects:* If `sz <= size()`, equivalent to calling `pop_back() size() - sz` times. If `size() < sz`, appends `sz - size()` default-inserted elements to the sequence.

4 *Requires:* `T` shall be `MoveInsertable` and `DefaultInsertable` into `*this`.

5 *Remarks:* If an exception is thrown other than by the move constructor of a non-`CopyInsertable` `T` there are no effects.

```
void resize(size_type sz, const T& c);
```

6 *Effects:* If `sz <= size()`, equivalent to calling `pop_back() size() - sz` times. If `size() < sz`, appends `sz - size()` copies of `c` to the sequence.

7 *Requires:* `T` shall be `CopyInsertable` into `*this`.

8 *Remarks:* If an exception is thrown there are no effects.

23.801.0.1 `vector` data [vector.data]

```
T*         data() noexcept;
const T*   data() const noexcept;
```

1

Returns: A pointer such that `[data(),data() + size())` is a valid range. For a non-empty vector, `data() == &front()`.

1 *Complexity:* Constant time.

23.806.0.1 `vector` modifiers [vector.modifiers]

```
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template <class InputIterator>
  iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);

template <class... Args> void emplace_back(Args&&... args);
template <class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_back(const T& x);
void push_back(T&& x);
```

1

Remarks: Causes reallocation if the new size is greater than the old capacity. If no reallocation happens, all the iterators and references before the insertion point remain valid. If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of `T` or by any `InputIterator` operation there are no effects. If an exception is thrown while inserting a single element at the end and `T` is `CopyInsertable` or `is_nothrow_move_constructible<T>::value` is `true`, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-`CopyInsertable` `T`, the effects are unspecified.

1

Complexity: The complexity is linear in the number of elements inserted plus the distance to the end of the vector.

```
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
```

1

Effects: Invalidates iterators and references at or after the point of the erase.

1

Complexity: The destructor of `T` is called the number of times equal to the number of the elements erased, but the move assignment operator of `T` is called the number of times equal to the number of elements in the vector after the erased elements.

1 *Throws:* Nothing unless an exception is thrown by the copy constructor, move constructor, assignment operator, or move assignment operator of `T`.

23.890.0.1 `vector` specialized algorithms [vector.special]

```
template <class T, class Allocator>
  void swap(vector<T,Allocator>& x, vector<T,Allocator>& y);
```

1 *Effects:*

```
x.swap(y);
```

23.890.1 Class `vector<bool>` [vector.bool]

1

To optimize space allocation, a specialization of vector for `bool` elements is provided:

```
namespace std {
  template <class Allocator> class vector<bool, Allocator> {
  public:
    // types:
    typedef bool                                    const_reference;
    typedef implementation-defined                  iterator;       // see 23.2
    typedef implementation-defined                  const_iterator; // see 23.2
    typedef implementation-defined                  size_type;      // see 23.2
    typedef implementation-defined                  difference_type;// see 23.2
    typedef bool                                    value_type;
    typedef Allocator                               allocator_type;
    typedef implementation-defined                  pointer;
    typedef implementation-defined                  const_pointer;
    typedef std::reverse_iterator<iterator>         reverse_iterator;
    typedef std::reverse_iterator<const_iterator>   const_reverse_iterator;

    // bit reference:
    class reference {
      friend class vector;
      reference() noexcept;
    public:
      ~reference();
      operator bool() const noexcept;
      reference& operator=(const bool x) noexcept;
      reference& operator=(const reference& x) noexcept;
      void flip() noexcept;     // flips the bit
```

```
};

// construct/copy/destroy:
vector() : vector(Allocator()) { }
explicit vector(const Allocator&);
explicit vector(size_type n, const Allocator& = Allocator());
vector(size_type n, const bool& value,
       const Allocator& = Allocator());
template <class InputIterator>
  vector(InputIterator first, InputIterator last,
         const Allocator& = Allocator());
vector(const vector<bool,Allocator>& x);
vector(vector<bool,Allocator>&& x);
vector(const vector&, const Allocator&);
vector(vector&&, const Allocator&);
vector(initializer_list<bool>, const Allocator& = Allocator()));
~vector();
vector<bool,Allocator>& operator=(const vector<bool,Allocator>& x);
vector<bool,Allocator>& operator=(vector<bool,Allocator>&& x);
vector& operator=(initializer_list<bool>);
template <class InputIterator>
  void assign(InputIterator first, InputIterator last);
void assign(size_type n, const bool& t);
void assign(initializer_list<bool>);
allocator_type get_allocator() const noexcept;

// iterators:
iterator               begin() noexcept;
const_iterator         begin() const noexcept;
iterator               end() noexcept;
const_iterator         end() const noexcept;
reverse_iterator       rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator       rend() noexcept;
const_reverse_iterator rend() const noexcept;

const_iterator         cbegin() const noexcept;
const_iterator         cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// capacity:
size_type size() const noexcept;
size_type max_size() const noexcept;
void      resize(size_type sz, bool c = false);
size_type capacity() const noexcept;
bool      empty() const noexcept;
void      reserve(size_type n);
void      shrink_to_fit();

// element access:
reference       operator[](size_type n);
const_reference operator[](size_type n) const;
const_reference at(size_type n) const;
reference       at(size_type n);
```

```
    reference       front();
    const_reference front() const;
    reference       back();
    const_reference back() const;

    // modifiers:
    template <class... Args> void emplace_back(Args&&... args);
    void push_back(const bool& x);
    void pop_back();
    template <class... Args> iterator emplace(const_iterator position, Args&&... args);
    iterator insert(const_iterator position, const bool& x);
    iterator insert (const_iterator position, size_type n, const bool& x);
    template <class InputIterator>
        iterator insert(const_iterator position,
                        InputIterator first, InputIterator last);
    iterator insert(const_iterator position, initializer_list<bool> il);

    iterator erase(const_iterator position);
    iterator erase(const_iterator first, const_iterator last);
    void swap(vector<bool,Allocator>&);
    static void swap(reference x, reference y) noexcept;
    void flip() noexcept;       // flips all bits
    void clear() noexcept;
  };
}
```

1

Unless described below, all operations have the same requirements and semantics as the primary `vector` template, except that operations dealing with the `bool` value type map to bit values in the container storage and allocator_traits::construct (20.89.0.1) is not used to construct these values.

1

There is no requirement that the data be stored as a contiguous allocation of `bool` values. A space-optimized representation of bits is recommended instead.

1 `reference` is a class that simulates the behavior of references of a single bit in `vector<bool>`. The conversion operator returns `true` when the bit is set, and `false` otherwise. The assignment operator sets the bit when the argument is (convertible to) `true` and clears it otherwise. `flip` reverses the state of the bit.

`void flip() noexcept;`

2 *Effects:* Replaces each element in the container with its complement.

`static void swap(reference x, reference y) noexcept;`

3 *Effects:* exchanges the contents of `x` and `y` as if by

```
bool b = x;
x = y;
y = b;
```

`template <class Allocator> struct hash<vector<bool, Allocator> >;`

4 The template specialization shall meet the requirements of class template `hash` (20.443.1).

23.894 Associative containers [associative]

23.894.1 In general [associative.general]

1 The header `<map>` defines the class templates `map` and `multimap`; the header `<set>` defines the class templates `set` and `multiset`.

23.894.2 Header `<map>` synopsis [associative.map.syn]

```
#include <initializer_list>

namespace std {

  template <class Key, class T, class Compare = less<Key>,
            class Allocator = allocator<pair<const Key, T> > >
    class map;
  template <class Key, class T, class Compare, class Allocator>
    bool operator==(const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator< (const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator!=(const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator> (const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator>=(const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator<=(const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    void swap(map<Key,T,Compare,Allocator>& x,
              map<Key,T,Compare,Allocator>& y);

  template <class Key, class T, class Compare = less<Key>,
            class Allocator = allocator<pair<const Key, T> > >
    class multimap;
  template <class Key, class T, class Compare, class Allocator>
    bool operator==(const multimap<Key,T,Compare,Allocator>& x,
                    const multimap<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator< (const multimap<Key,T,Compare,Allocator>& x,
                    const multimap<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator!=(const multimap<Key,T,Compare,Allocator>& x,
                    const multimap<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator> (const multimap<Key,T,Compare,Allocator>& x,
                    const multimap<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator>=(const multimap<Key,T,Compare,Allocator>& x,
                    const multimap<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
```

```
    bool operator<=(const multimap<Key,T,Compare,Allocator>& x,
                    const multimap<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    void swap(multimap<Key,T,Compare,Allocator>& x,
              multimap<Key,T,Compare,Allocator>& y);
}
```

23.894.3 Header <set> synopsis [associative.set.syn]

```
#include <initializer_list>

namespace std {

  template <class Key, class Compare = less<Key>,
            class Allocator = allocator<Key> >
    class set;
  template <class Key, class Compare, class Allocator>
    bool operator==(const set<Key,Compare,Allocator>& x,
                    const set<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    bool operator< (const set<Key,Compare,Allocator>& x,
                    const set<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    bool operator!=(const set<Key,Compare,Allocator>& x,
                    const set<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    bool operator> (const set<Key,Compare,Allocator>& x,
                    const set<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    bool operator>=(const set<Key,Compare,Allocator>& x,
                    const set<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    bool operator<=(const set<Key,Compare,Allocator>& x,
                    const set<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    void swap(set<Key,Compare,Allocator>& x,
              set<Key,Compare,Allocator>& y);

  template <class Key, class Compare = less<Key>,
            class Allocator = allocator<Key> >
    class multiset;
  template <class Key, class Compare, class Allocator>
    bool operator==(const multiset<Key,Compare,Allocator>& x,
                    const multiset<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    bool operator< (const multiset<Key,Compare,Allocator>& x,
                    const multiset<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    bool operator!=(const multiset<Key,Compare,Allocator>& x,
                    const multiset<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    bool operator> (const multiset<Key,Compare,Allocator>& x,
                    const multiset<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    bool operator>=(const multiset<Key,Compare,Allocator>& x,
                    const multiset<Key,Compare,Allocator>& y);
```

```
  template <class Key, class Compare, class Allocator>
    bool operator<=(const multiset<Key,Compare,Allocator>& x,
                    const multiset<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    void swap(multiset<Key,Compare,Allocator>& x,
              multiset<Key,Compare,Allocator>& y);
}
```

23.894.4 Class template map [map]

23.894.4.1 Class template map overview [map.overview]

1 A map is an associative container that supports unique keys (contains at most one of each key value) and provides for fast retrieval of values of another type T based on the keys. The map class supports bidirectional iterators.

2

A map satisfies all of the requirements of a container, of a reversible container (23.2), of an associative container (23.294.1), and of an allocator-aware container (Table 99). A map also provides most operations described in (23.294.1) for unique keys. This means that a map supports the a_uniq operations in (23.294.1) but not the a_eq operations. For a map<Key,T> the key_type is Key and the value_type is pair<const Key,T>. Descriptions are provided here only for operations on map that are not described in one of those tables or for operations where there is additional semantic information.

```
namespace std {
  template <class Key, class T, class Compare = less<Key>,
            class Allocator = allocator<pair<const Key, T> > >
  class map {
  public:
    // types:
    typedef Key                                    key_type;
    typedef T                                      mapped_type;
    typedef pair<const Key, T>                     value_type;
    typedef Compare                                key_compare;
    typedef Allocator                              allocator_type;
    typedef value_type&                            reference;
    typedef const value_type&                      const_reference;
    typedef implementation-defined                 iterator;       // see 23.2
    typedef implementation-defined                 const_iterator; // see 23.2
    typedef implementation-defined                 size_type;      // see 23.2
    typedef implementation-defined                 difference_type;// see 23.2
    typedef typename allocator_traits<Allocator>::pointer           pointer;
    typedef typename allocator_traits<Allocator>::const_pointer     const_pointer;
    typedef std::reverse_iterator<iterator>        reverse_iterator;
    typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

    class value_compare {
    friend class map;
    protected:
      Compare comp;
      value_compare(Compare c) : comp(c) {}
    public:
      typedef bool result_type;
      typedef value_type first_argument_type;
      typedef value_type second_argument_type;
      bool operator()(const value_type& x, const value_type& y) const {
```

```
    return comp(x.first, y.first);
  }
};

// 23.896.0.1, construct/copy/destroy:

    pair<iterator, iterator>             equal_range(const K& x);
  template <class K>
    pair<const_iterator, const_iterator> equal_range(const K& x) const;
};

template <class Key, class T, class Compare, class Allocator>
  bool operator==(const map<Key,T,Compare,Allocator>& x,
```

```
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator< (const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator!=(const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator> (const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator>=(const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);
  template <class Key, class T, class Compare, class Allocator>
    bool operator<=(const map<Key,T,Compare,Allocator>& x,
                    const map<Key,T,Compare,Allocator>& y);

  // specialized algorithms:
  template <class Key, class T, class Compare, class Allocator>
    void swap(map<Key,T,Compare,Allocator>& x,
              map<Key,T,Compare,Allocator>& y);
}
```

23.896.0.1 `map` constructors, copy, and assignment [map.cons]

```
explicit map(const Compare& comp,
             const Allocator& = Allocator());
```

1 *Effects:* Constructs an empty `map` using the specified comparison object and allocator.

2 *Complexity:* Constant.

```
template <class InputIterator>
  map(InputIterator first, InputIterator last,
      const Compare& comp = Compare(), const Allocator& = Allocator());
```

3 *Requires:* If the iterator's indirection operator returns an lvalue or a const rvalue `pair<key_type, mapped_type>`, then both `key_type` and `mapped_type` shall be `CopyInsertable` into `*this`.

4 *Effects:* Constructs an empty `map` using the specified comparison object and allocator, and inserts elements from the range `[first,last)`.

5 *Complexity:* Linear in N if the range `[first,last)` is already sorted using `comp` and otherwise $N \log N$, where N is `last - first`.

23.896.0.2 `map` element access [map.access]

```
T& operator[](const key_type& x);
```

1

Effects: If there is no key equivalent to `x` in the map, inserts `value_type(x, T())` into the map.

1

Requires: `key_type` shall be `CopyInsertable` and `mapped_type` shall be `DefaultInsertable` into `*this`.

1 *Returns:* A reference to the `mapped_type` corresponding to `x` in `*this`.

2 *Complexity:* Logarithmic.

```
T& operator[](key_type&& x);
```

3

Effects: If there is no key equivalent to `x` in the map, inserts `value_type(std::move(x), T())` into the map.

1 *Requires:* `mapped_type` shall be `DefaultInsertable` into `*this`.

2 *Returns:* A reference to the `mapped_type` corresponding to `x` in `*this`.

3

Complexity: Logarithmic.

```
T&       at(const key_type& x);
const T& at(const key_type& x) const;
```

1 *Returns:* A reference to the `mapped_type` corresponding to `x` in `*this`.

2

Throws: An exception object of type `out_of_range` if no such element is present.

1 *Complexity:* Logarithmic.

23.924.0.1 `map` modifiers [map.modifiers]

```
template <class P> pair<iterator, bool> insert(P&& x);
template <class P> iterator insert(const_iterator position, P&& x);
template <class InputIterator>
  void insert(InputIterator first, InputIterator last);
```

1

Effects: The first form is equivalent to `return emplace(std::forward<P>(x))`. The second form is equivalent to `return emplace_hint(position, std::forward<P>(x))`.

1 *Remarks:* These signatures shall not participate in overload resolution unless `std::is_constructible<value_type, P&&>::value` is `true`.

23.925.0.1 `map` specialized algorithms [map.special]

```
template <class Key, class T, class Compare, class Allocator>
  void swap(map<Key,T,Compare,Allocator>& x,
            map<Key,T,Compare,Allocator>& y);
```

1 *Effects:*

```
x.swap(y);
```

23.925.1 Class template `multimap` [multimap]

23.925.1.1 Class template `multimap` overview [multimap.overview]

1

A `multimap` is an associative container that supports equivalent keys (possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type `T` based on the keys. The `multimap` class supports bidirectional iterators.

1 A `multimap` satisfies all of the requirements of a container and of a reversible container (23.2), of an associative container (23.294.1), and of an allocator-aware container (Table 99). A `multimap` also provides most operations described in (23.294.1) for equal keys. This means that a `multimap` supports the `a_eq` operations in (23.294.1) but not the `a_uniq` operations. For a `multimap<Key,T>` the `key_type` is `Key` and

the `value_type` is `pair<const Key,T>`. Descriptions are provided here only for operations on `multimap` that are not described in one of those tables or for operations where there is additional semantic information.

```
namespace std {
  template <class Key, class T, class Compare = less<Key>,
            class Allocator = allocator<pair<const Key, T> > >
  class multimap {
  public:
    // types:
    typedef Key                                  key_type;
    typedef T                                    mapped_type;
    typedef pair<const Key,T>                    value_type;
    typedef Compare                              key_compare;
    typedef Allocator                            allocator_type;
    typedef value_type&                          reference;
    typedef const value_type&                    const_reference;
    typedef implementation-defined               iterator;       // see 23.2
    typedef implementation-defined               const_iterator; // see 23.2
    typedef implementation-defined               size_type;      // see 23.2

23.928.0.1 multimap constructors [multimap.cons]

```
explicit multimap(const Compare& comp,
                  const Allocator& = Allocator());
```

1 *Effects:* Constructs an empty `multimap` using the specified comparison object and allocator.

2 *Complexity:* Constant.

```
template <class InputIterator>
  multimap(InputIterator first, InputIterator last,
           const Compare& comp = Compare(),
           const Allocator& = Allocator());
```

3 *Requires:* If the iterator's indirection operator returns an lvalue or a const rvalue `pair<key_type, mapped_type>`, then both `key_type` and `mapped_type` shall be `CopyInsertable` into `*this`.

4 *Effects:* Constructs an empty `multimap` using the specified comparison object and allocator, and inserts elements from the range `[first,last)`.

5 *Complexity:* Linear in N if the range `[first,last)` is already sorted using `comp` and otherwise $N \log N$, where N is `last - first`.

23.928.0.2 `multimap` modifiers [multimap.modifiers]

```
template <class P> iterator insert(P&& x);
template <class P> iterator insert(const_iterator position, P&& x);
```

1 *Effects:* The first form is equivalent to `return emplace(std::forward<P>(x))`. The second form is equivalent to `return emplace_hint(position, std::forward<P>(x))`.

2 *Remarks:* These signatures shall not participate in overload resolution unless `std::is_constructible<value_type, P&&>::value` is `true`.

23.928.0.3 `multimap` specialized algorithms [multimap.special]

```
template <class Key, class T, class Compare, class Allocator>
  void swap(multimap<Key,T,Compare,Allocator>& x,
            multimap<Key,T,Compare,Allocator>& y);
```

1 *Effects:*

```
x.swap(y);
```

23.928.1 Class template `set` [set]

23.928.1.1 Class template `set` overview [set.overview]

1

A `set` is an associative container that supports unique keys (contains at most one of each key value) and provides for fast retrieval of the keys themselves. The `set` class supports bidirectional iterators.

1

A `set` satisfies all of the requirements of a container, of a reversible container (23.2), of an associative container (23.294.1), and of an allocator-aware container (Table 99). A `set` also provides most operations described in (23.294.1) for unique keys. This means that a `set` supports the `a_uniq` operations in (23.294.1) but not the `a_eq` operations. For a `set<Key>` both the `key_type` and `value_type` are `Key`. Descriptions are provided here only for operations on `set` that are not described in one of these tables and for operations where there is additional semantic information.

```
namespace std {
  template <class Key, class Compare = less<Key>,
            class Allocator = allocator<Key> >
  class set {
  public:
```

```
// types:
typedef Key                                    key_type;
typedef Key                                    value_type;
typedef Compare                                key_compare;
typedef Compare                                value_compare;
typedef Allocator                              allocator_type;
typedef value_type&                            reference;

```

23.931.0.1 set constructors, copy, and assignment [set.cons]

```
explicit set(const Compare& comp,
             const Allocator& = Allocator());
```

1 *Effects:* Constructs an empty set using the specified comparison objects and allocator.

2 *Complexity:* Constant.

```
template <class InputIterator>
  set(InputIterator first, InputIterator last,
      const Compare& comp = Compare(), const Allocator& = Allocator());
```

3 *Effects:* Constructs an empty `set` using the specified comparison object and allocator, and inserts elements from the range `[first,last)`.

4 *Requires:* If the iterator's indirection operator returns an lvalue or a non-const rvalue, then `Key` shall be `CopyInsertable` into `*this`.

5 *Complexity:* Linear in N if the range `[first,last)` is already sorted using `comp` and otherwise $N \log N$, where N is `last - first`.

23.931.0.2 set specialized algorithms [set.special]

```
template <class Key, class Compare, class Allocator>
  void swap(set<Key,Compare,Allocator>& x,
            set<Key,Compare,Allocator>& y);
```

1 *Effects:*

```
x.swap(y);
```

23.931.1 Class template multiset [multiset]

23.931.1.1 Class template multiset overview [multiset.overview]

1 A multiset is an associative container that supports equivalent keys (possibly contains multiple copies of the same key value) and provides for fast retrieval of the keys themselves. The multiset class supports bidirectional iterators.

2 A multiset satisfies all of the requirements of a container, of a reversible container (23.2), of an associative container (23.294.1), and of an allocator-aware container (Table 99). multiset also provides most operations described in (23.294.1) for duplicate keys. This means that a multiset supports the a_eq operations in (23.294.1) but not the a_uniq operations. For a multiset<Key> both the key_type and value_type are Key. Descriptions are provided here only for operations on multiset that are not described in one of these tables and for operations where there is additional semantic information.

```
namespace std {
  template <class Key, class Compare = less<Key>,
            class Allocator = allocator<Key> >
  class multiset {
  public:
    // types:
    typedef Key                                                    key_type;
    typedef Key                                                    value_type;
    typedef Compare                                                key_compare;
    typedef Compare                                                value_compare;
    typedef Allocator                                              allocator_type;
    typedef value_type&                                            reference;
    typedef const value_type&                                      const_reference;

                    const multiset<Key,Compare,Allocator>& y);
  template <class Key, class Compare, class Allocator>
    bool operator<=(const multiset<Key,Compare,Allocator>& x,
                    const multiset<Key,Compare,Allocator>& y);

  // specialized algorithms:
  template <class Key, class Compare, class Allocator>
    void swap(multiset<Key,Compare,Allocator>& x,
              multiset<Key,Compare,Allocator>& y);
}
```

23.931.1.2 `multiset` constructors [multiset.cons]

```
explicit multiset(const Compare& comp,
                  const Allocator& = Allocator());
```

1 *Effects:* Constructs an empty set using the specified comparison object and allocator.

2 *Complexity:* Constant.

```
template <class InputIterator>
```

```
multiset(InputIterator first, InputIterator last,
         const Compare& comp = Compare(), const Allocator& = Allocator());
```

3 *Requires:* If the iterator's indirection operator returns an lvalue or a const rvalue, then `Key` shall be `CopyInsertable` into `*this`.

4 *Effects:* Constructs an empty `multiset` using the specified comparison object and allocator, and inserts elements from the range `[first,last)`.

5 *Complexity:* Linear in N if the range `[first,last)` is already sorted using `comp` and otherwise $N \log N$, where N is `last - first`.

23.931.1.3 `multiset` specialized algorithms [multiset.special]

```
template <class Key, class Compare, class Allocator>
  void swap(multiset<Key,Compare,Allocator>& x,
            multiset<Key,Compare,Allocator>& y);
```

1 *Effects:*

```
x.swap(y);
```

23.932 Unordered associative containers [unord]

23.932.1 In general [unord.general]

1 The header `<unordered_map>` defines the class templates `unordered_map` and `unordered_multimap`; the header `<unordered_set>` defines the class templates `unordered_set` and `unordered_multiset`.

23.932.2 Header `<unordered_map>` synopsis [unord.map.syn]

```
#include <initializer_list>

namespace std {

  // 23.932.4, class template unordered_map:
  template <class Key,
            class T,
            class Hash = hash<Key>,
            class Pred = std::equal_to<Key>,
            class Alloc = std::allocator<std::pair<const Key, T> > >
    class unordered_map;

  // 23.936.1, class template unordered_multimap:
  template <class Key,
            class T,
            class Hash = hash<Key>,
            class Pred = std::equal_to<Key>,
            class Alloc = std::allocator<std::pair<const Key, T> > >
    class unordered_multimap;

  template <class Key, class T, class Hash, class Pred, class Alloc>
    void swap(unordered_map<Key, T, Hash, Pred, Alloc>& x,
              unordered_map<Key, T, Hash, Pred, Alloc>& y);

  template <class Key, class T, class Hash, class Pred, class Alloc>
    void swap(unordered_multimap<Key, T, Hash, Pred, Alloc>& x,
              unordered_multimap<Key, T, Hash, Pred, Alloc>& y);
```

```
  template <class Key, class T, class Hash, class Pred, class Alloc>
    bool operator==(const unordered_map<Key, T, Hash, Pred, Alloc>& a,
                    const unordered_map<Key, T, Hash, Pred, Alloc>& b);
  template <class Key, class T, class Hash, class Pred, class Alloc>
    bool operator!=(const unordered_map<Key, T, Hash, Pred, Alloc>& a,

  template <class Key, class T, class Hash, class Pred, class Alloc>
    bool operator!=(const unordered_multimap<Key, T, Hash, Pred, Alloc>& a,
                    const unordered_multimap<Key, T, Hash, Pred, Alloc>& b);
} // namespace std
```

23.932.3 Header <unordered_set> synopsis [unord.set.syn]

```
#include <initializer_list>

namespace std {

  // 23.937.1, class template unordered_set:
  template <class Key,
            class Hash = hash<Key>,
            class Pred = std::equal_to<Key>,
            class Alloc = std::allocator<Key> >
    class unordered_set;

  // 23.938.1, class template unordered_multiset:
  template <class Key,
            class Hash = hash<Key>,
            class Pred = std::equal_to<Key>,
            class Alloc = std::allocator<Key> >
    class unordered_multiset;

  template <class Key, class Hash, class Pred, class Alloc>
    void swap(unordered_set<Key, Hash, Pred, Alloc>& x,
              unordered_set<Key, Hash, Pred, Alloc>& y);

  template <class Key, class Hash, class Pred, class Alloc>
    void swap(unordered_multiset<Key, Hash, Pred, Alloc>& x,
              unordered_multiset<Key, Hash, Pred, Alloc>& y);

  template <class Key, class Hash, class Pred, class Alloc>
    bool operator==(const unordered_set<Key, Hash, Pred, Alloc>& a,
                    const unordered_set<Key, Hash, Pred, Alloc>& b);
  template <class Key, class Hash, class Pred, class Alloc>
    bool operator!=(const unordered_set<Key, Hash, Pred, Alloc>& a,
                    const unordered_set<Key, Hash, Pred, Alloc>& b);
  template <class Key, class Hash, class Pred, class Alloc>
    bool operator==(const unordered_multiset<Key, Hash, Pred, Alloc>& a,
                    const unordered_multiset<Key, Hash, Pred, Alloc>& b);
  template <class Key, class Hash, class Pred, class Alloc>
    bool operator!=(const unordered_multiset<Key, Hash, Pred, Alloc>& a,
                    const unordered_multiset<Key, Hash, Pred, Alloc>& b);
} // namespace std
```

23.932.4 Class template unordered_map [unord.map]

23.932.4.1 Class template unordered_map overview [unord.map.overview]

1

An unordered_map is an unordered associative container that supports unique keys (an unordered_map contains at most one of each key value) and that associates values of another type mapped_type with the keys. The unordered_map class supports forward iterators.

1 An unordered_map satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 99). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_map supports the a_uniq operations in that table, not the a_eq operations. For an unordered_map<Key, T> the key type is Key, the mapped type is T, and the value type is std::pair<const Key, T>.

2 This section only describes operations on unordered_map that are not described in one of the requirement tables, or for which there is additional semantic information.

```
namespace std {
  template <class Key,
            class T,
            class Hash  = hash<Key>,
            class Pred  = std::equal_to<Key>,
            class Allocator = std::allocator<std::pair<const Key, T> > >
  class unordered_map
  {
  public:
    // types
    typedef Key                                                 key_type;
    typedef std::pair<const Key, T>                             value_type;
    typedef T                                                   mapped_type;
    typedef Hash                                                hasher;
    typedef Pred                                                key_equal;
    typedef Allocator                                           allocator_type;

                       const allocator_type& a = allocator_type());
```

1 *Effects:* Constructs an empty `unordered_map` using the specified hash function, key equality function, and allocator, and using at least *n* buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns 1.0.

2 *Complexity:* Constant.

```
template <class InputIterator>
  unordered_map(InputIterator f, InputIterator l,
                size_type n = see below,
                const hasher& hf = hasher(),
                const key_equal& eql = key_equal(),
                const allocator_type& a = allocator_type());
```

3 *Effects:* Constructs an empty `unordered_map` using the specified hash function, key equality function, and allocator, and using at least *n* buckets. If *n* is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f, l)`. `max_load_factor()` returns 1.0.

4 *Complexity:* Average case linear, worst case quadratic.

23.933.0.2 unordered_map element access [unord.map.elem]

```
mapped_type& operator[](const key_type& k);
mapped_type& operator[](key_type&& k);
```

1 *Requires:* `mapped_type` shall be `DefaultInsertable` into `*this`. For the first operator, `key_type` shall be `CopyInsertable` into `*this`. For the second operator, `key_type` shall be `MoveConstructible`.

2

Effects: If the `unordered_map` does not already contain an element whose key is equivalent to *k*, the first operator inserts the value `value_type(k, mapped_type())` and the second operator inserts the value `value_type(std::move(k), mapped_type())`.

1

Returns: A reference to `x.second`, where `x` is the (unique) element whose key is equivalent to *k*.

1 *Complexity:* Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`size()`).

```
mapped_type& at(const key_type& k);
const mapped_type& at(const key_type& k) const;
```

2 *Returns:* A reference to `x.second`, where `x` is the (unique) element whose key is equivalent to `k`.

3 *Throws:* An exception object of type `out_of_range` if no such element is present.

23.936.0.1 unordered_map modifiers [unord.map.modifiers]

```
template <class P>
  pair<iterator, bool> insert(P&& obj);
```

1 *Effects:* Equivalent to `return emplace(std::forward<P>(obj))`.

2 *Remarks:* This signature shall not participate in overload resolution unless `std::is_constructible<value_type, P&&>::value` is `true`.

```
template <class P>
  iterator insert(const_iterator hint, P&& obj);
```

3 *Effects:* Equivalent to `return emplace_hint(hint, std::forward<P>(obj))`.

4 *Remarks:* This signature shall not participate in overload resolution unless `std::is_constructible<value_type, P&&>::value` is `true`.

23.936.0.2 `unordered_map` swap [unord.map.swap]

```
template <class Key, class T, class Hash, class Pred, class Alloc>
  void swap(unordered_map<Key, T, Hash, Pred, Alloc>& x,
            unordered_map<Key, T, Hash, Pred, Alloc>& y);
```

1 *Effects:* `x.swap(y)`.

23.936.1 Class template `unordered_multimap` [unord.multimap]

23.936.1.1 Class template `unordered_multimap` overview [unord.multimap.overview]

1

An `unordered_multimap` is an unordered associative container that supports equivalent keys (an instance of `unordered_multimap` may contain multiple copies of each key value) and that associates values of another type `mapped_type` with the keys. The `unordered_multimap` class supports forward iterators.

1 An `unordered_multimap` satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 99). It provides the operations described in the preceding requirements table for equivalent keys; that is, an `unordered_multimap` supports the `a_eq` operations in that table, not the `a_uniq` operations. For an `unordered_multimap<Key, T>` the `key type` is `Key`, the mapped type is `T`, and the value type is `std::pair<const Key, T>`.

2 This section only describes operations on `unordered_multimap` that are not described in one of the requirement tables, or for which there is additional semantic information.

```
namespace std {
  template <class Key,
            class T,
            class Hash  = hash<Key>,
            class Pred  = std::equal_to<Key>,
            class Allocator = std::allocator<std::pair<const Key, T> > >
  class unordered_multimap
  {
  public:
    // types
    typedef Key                                                  key_type;
    typedef std::pair<const Key, T>                              value_type;
    typedef T                                                    mapped_type;
    typedef Hash                                                 hasher;

23.937.0.1 `unordered_multimap` constructors [unord.multimap.cnstr]

```
unordered_multimap() : unordered_multimap(size_type(see below)) { }
explicit unordered_multimap(size_type n,
                            const hasher& hf = hasher(),
                            const key_equal& eql = key_equal(),
                            const allocator_type& a = allocator_type());
```

1 *Effects:* Constructs an empty `unordered_multimap` using the specified hash function, key equality function, and allocator, and using at least *n* buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns 1.0.

2 *Complexity:* Constant.

```
template <class InputIterator>
  unordered_multimap(InputIterator f, InputIterator l,
                     size_type n = see below,
                     const hasher& hf = hasher(),
                     const key_equal& eql = key_equal(),
                     const allocator_type& a = allocator_type());
```

3 *Effects:* Constructs an empty `unordered_multimap` using the specified hash function, key equality function, and allocator, and using at least *n* buckets. If *n* is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[`*f*`, `*l*`)`. `max_load_factor()` returns 1.0.

4 *Complexity:* Average case linear, worst case quadratic.

23.937.0.2 `unordered_multimap` modifiers [unord.multimap.modifiers]

```
template <class P>
  iterator insert(P&& obj);
```

1 *Effects:* Equivalent to `return emplace(std::forward<P>(obj))`.

2 *Remarks:* This signature shall not participate in overload resolution unless `std::is_constructible<value_type, P&&>::value` is `true`.

```
template <class P>
  iterator insert(const_iterator hint, P&& obj);
```

3 *Effects:* Equivalent to `return emplace_hint(hint, std::forward<P>(obj))`.

4 *Remarks:* This signature shall not participate in overload resolution unless `std::is_constructible<value_type, P&&>::value` is `true`.

23.937.0.3 `unordered_multimap` swap [unord.multimap.swap]

```
template <class Key, class T, class Hash, class Pred, class Alloc>
  void swap(unordered_multimap<Key, T, Hash, Pred, Alloc>& x,
            unordered_multimap<Key, T, Hash, Pred, Alloc>& y);
```

1 *Effects:* `x.swap(y)`.

23.937.1 Class template `unordered_set` [unord.set]

23.937.1.1 Class template `unordered_set` overview [unord.set.overview]

1

An `unordered_set` is an unordered associative container that supports unique keys (an `unordered_set` contains at most one of each key value) and in which the elements' keys are the elements themselves. The `unordered_set` class supports forward iterators.

1 An `unordered_set` satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 99). It provides the operations described in the preceding requirements table for unique keys; that is, an `unordered_set` supports the `a_uniq` operations in that table, not the `a_eq` operations. For an `unordered_set<Key>` the `key type` and the value type are both `Key`. The `iterator` and `const_iterator` types are both const iterator types. It is unspecified whether they are the same type.

2 This section only describes operations on `unordered_set` that are not described in one of the requirement tables, or for which there is additional semantic information.

```
namespace std {
  template <class Key,
            class Hash  = hash<Key>,
            class Pred  = std::equal_to<Key>,
            class Allocator = std::allocator<Key> >
  class unordered_set
  {
  public:
    // types
    typedef Key                                                  key_type;
    typedef Key                                                  value_type;
    typedef Hash                                                 hasher;
    typedef Pred                                                 key_equal;
    typedef Allocator                                            allocator_type;
    typedef typename allocator_traits<Allocator>::pointer        pointer;
    typedef typename allocator_traits<Allocator>::const_pointer  const_pointer;
    typedef value_type&                                          reference;
    typedef const value_type&                                    const_reference;

                size_type n = see below,
                const hasher& hf = hasher(),
                const key_equal& eql = key_equal(),
                const allocator_type& a = allocator_type());
```

3 *Effects:* Constructs an empty `unordered_set` using the specified hash function, key equality function, and allocator, and using at least *n* buckets. If *n* is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[`*f*`, `*l*`)`. `max_load_factor()` returns 1.0.

4 *Complexity:* Average case linear, worst case quadratic.

23.938.0.2 `unordered_set` swap [unord.set.swap]

```
template <class Key, class Hash, class Pred, class Alloc>
  void swap(unordered_set<Key, Hash, Pred, Alloc>& x,
            unordered_set<Key, Hash, Pred, Alloc>& y);
```

1 *Effects:* `x.swap(y)`.

23.938.1 Class template `unordered_multiset` [unord.multiset]

23.938.1.1 Class template `unordered_multiset` overview [unord.multiset.overview]

1 An `unordered_multiset` is an unordered associative container that supports equivalent keys (an instance of `unordered_multiset` may contain multiple copies of the same key value) and in which each element's key is the element itself. The `unordered_multiset` class supports forward iterators.

2 An `unordered_multiset` satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 99). It provides the operations described in the preceding requirements table for equivalent keys; that is, an `unordered_multiset` supports the `a_eq` operations in that table, not the `a_uniq` operations. For an `unordered_multiset<Key>` the `key type` and the value type are both `Key`. The `iterator` and `const_iterator` types are both const iterator types. It is unspecified whether they are the same type.

3 This section only describes operations on `unordered_multiset` that are not described in one of the requirement tables, or for which there is additional semantic information.

```
namespace std {
  template <class Key,
            class Hash  = hash<Key>,
            class Pred  = std::equal_to<Key>,
            class Allocator = std::allocator<Key> >
  class unordered_multiset
```

```
{
public:
  // types
  typedef Key                                                  key_type;
  typedef Key                                                  value_type;
  typedef Hash                                                 hasher;
  typedef Pred                                                 key_equal;
  typedef Allocator                                            allocator_type;
  typedef typename allocator_traits<Allocator>::pointer        pointer;
  typedef typename allocator_traits<Allocator>::const_pointer  const_pointer;

                      const unordered_multiset<Key, Hash, Pred, Alloc>& b);
}
```

23.938.1.2 `unordered_multiset` constructors [unord.multiset.cnstr]

```
unordered_multiset() : unordered_multiset(size_type(see below)) { }
explicit unordered_multiset(size_type n,
                            const hasher& hf = hasher(),
                            const key_equal& eql = key_equal(),
                            const allocator_type& a = allocator_type());
```

1 *Effects:* Constructs an empty `unordered_multiset` using the specified hash function, key equality function, and allocator, and using at least *n* buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns 1.0.

2 *Complexity:* Constant.

```
template <class InputIterator>
  unordered_multiset(InputIterator f, InputIterator l,
                     size_type n = see below,
                     const hasher& hf = hasher(),
                     const key_equal& eql = key_equal(),
                     const allocator_type& a = allocator_type());
```

3 *Effects:* Constructs an empty `unordered_multiset` using the specified hash function, key equality function, and allocator, and using at least *n* buckets. If *n* is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[`*f*`, `*l*`)`. `max_load_factor()` returns 1.0.

4 *Complexity:* Average case linear, worst case quadratic.

23.938.1.3 `unordered_multiset` swap [unord.multiset.swap]

```
template <class Key, class Hash, class Pred, class Alloc>
```

```
void swap(unordered_multiset<Key, Hash, Pred, Alloc>& x,
          unordered_multiset<Key, Hash, Pred, Alloc>& y);
```

1 *Effects:* `x.swap(y);`

23.939 Container adaptors [container.adaptors]

23.939.1 In general [container.adaptors.general]

1 The headers `<queue>` and `<stack>` define the container adaptors `queue`, `priority_queue`, and `stack`.

2 The container adaptors each take a `Container` template parameter, and each constructor takes a `Container` reference argument. This container is copied into the `Container` member of each adaptor. If the container takes an allocator, then a compatible allocator may be passed in to the adaptor's constructor. Otherwise, normal copy or move construction is used for the container argument.

3 For container adaptors, no `swap` function throws an exception unless that exception is thrown by the swap of the adaptor's `Container` or `Compare` object (if any).

23.939.2 Header `<queue>` synopsis [queue.syn]

```
#include <initializer_list>

namespace std {

  template <class T, class Container = deque<T> > class queue;
  template <class T, class Container = vector<T>,
    class Compare = less<typename Container::value_type> >
      class priority_queue;

  template <class T, class Container>
    bool operator==(const queue<T, Container>& x,const queue<T, Container>& y);
  template <class T, class Container>
    bool operator< (const queue<T, Container>& x,const queue<T, Container>& y);
  template <class T, class Container>
    bool operator!=(const queue<T, Container>& x,const queue<T, Container>& y);
  template <class T, class Container>
    bool operator> (const queue<T, Container>& x,const queue<T, Container>& y);
  template <class T, class Container>
    bool operator>=(const queue<T, Container>& x,const queue<T, Container>& y);
  template <class T, class Container>
    bool operator<=(const queue<T, Container>& x,const queue<T, Container>& y);

  template <class T, class Container>
    void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));
  template <class T, class Container, class Compare>
    void swap(priority_queue<T, Container, Compare>& x,
              priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));
}
```

23.939.3 Class template `queue` [queue]

23.939.3.1 `queue` definition [queue.defn]

1

Any sequence container supporting operations `front()`, `back()`, `push_back()` and `pop_front()` can be used to instantiate `queue`. In particular, `list` (23.672.1) and `deque` (23.588.1) can be used.

```
namespace std {
```

```
  template <class T, class Container = deque<T> >
  class queue {
  public:
    typedef typename Container::value_type           value_type;
    typedef typename Container::reference            reference;
    typedef typename Container::const_reference      const_reference;
    typedef typename Container::size_type            size_type;
    typedef          Container                       container_type;
  protected:
    Container c;

  public:
    explicit queue(const Container&);
    explicit queue(Container&& = Container());
    template <class Alloc> explicit queue(const Alloc&);
    template <class Alloc> queue(const Container&, const Alloc&);
    template <class Alloc> queue(Container&&, const Alloc&);
    template <class Alloc> queue(const queue&, const Alloc&);
    template <class Alloc> queue(queue&&, const Alloc&);

    bool              empty() const     { return c.empty(); }
    size_type         size()  const     { return c.size(); }
    reference         front()           { return c.front(); }
    const_reference   front() const     { return c.front(); }
    reference         back()            { return c.back(); }
    const_reference   back() const      { return c.back(); }
    void push(const value_type& x)      { c.push_back(x); }
    void push(value_type&& x)           { c.push_back(std::move(x)); }
    template <class... Args> void emplace(Args&&... args)
      { c.emplace_back(std::forward<Args>(args)...); }
    void pop()                          { c.pop_front(); }
    void swap(queue& q) noexcept(noexcept(swap(c, q.c)))
      { using std::swap; swap(c, q.c); }
  };

  template <class T, class Container>
    bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);
  template <class T, class Container>
    bool operator< (const queue<T, Container>& x, const queue<T, Container>& y);
  template <class T, class Container>
    bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);
  template <class T, class Container>
    bool operator> (const queue<T, Container>& x, const queue<T, Container>& y);
  template <class T, class Container>
    bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);
  template <class T, class Container>
    bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);

  template <class T, class Container>
    void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));

  template <class T, class Container, class Alloc>
    struct uses_allocator<queue<T, Container>, Alloc>
      : uses_allocator<Container, Alloc>::type { };
}
```

23.941.0.1 queue constructors [queue.cons]

```
explicit queue(const Container& cont);
```

1 *Effects:* Initializes `c` with `cont`.

```
explicit queue(Container&& cont = Container());
```

2 *Effects:* Initializes `c` with `std::move(cont)`.

23.941.0.2 queue constructors with allocators [queue.cons.alloc]

1 If `uses_allocator<container_type, Alloc>::value` is `false` the constructors in this subclause shall not participate in overload resolution.

```
template <class Alloc>
  explicit queue(const Alloc& a);
```

2 *Effects:* Initializes `c` with `a`.

```
template <class Alloc>
  queue(const container_type& cont, const Alloc& a);
```

3 *Effects:* Initializes `c` with `cont` as the first argument and `a` as the second argument.

```
template <class Alloc>
  queue(container_type&& cont, const Alloc& a);
```

4 *Effects:* Initializes `c` with `std::move(cont)` as the first argument and `a` as the second argument.

```
template <class Alloc>
  queue(const queue& q, const Alloc& a);
```

5 *Effects:* Initializes `c` with `q.c` as the first argument and `a` as the second argument.

```
template <class Alloc>
  queue(queue&& q, const Alloc& a);
```

6 *Effects:* Initializes `c` with `std::move(q.c)` as the first argument and `a` as the second argument.

23.941.0.3 queue operators [queue.ops]

```
template <class T, class Container>
    bool operator==(const queue<T, Container>& x,
                    const queue<T, Container>& y);
```

1 *Returns:* `x.c == y.c`.

```
template <class T, class Container>
    bool operator!=(const queue<T, Container>& x,
                    const queue<T, Container>& y);
```

2 *Returns:* `x.c != y.c`.

```
template <class T, class Container>
    bool operator< (const queue<T, Container>& x,
                    const queue<T, Container>& y);
```

3 *Returns:* `x.c < y.c`.

```
template <class T, class Container>
    bool operator<=(const queue<T, Container>& x,
                    const queue<T, Container>& y);
```

4 *Returns:* `x.c <= y.c`.

```
template <class T, class Container>
    bool operator> (const queue<T, Container>& x,
                    const queue<T, Container>& y);
```

5 *Returns:* `x.c > y.c`.

```
template <class T, class Container>
    bool operator>=(const queue<T, Container>& x,
                    const queue<T, Container>& y);
```

6 *Returns:* `x.c >= y.c`.

23.941.0.4 queue specialized algorithms [queue.special]

```
template <class T, class Container>
  void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));
```

1 *Effects:* `x.swap(y)`.

23.941.1 Class template `priority_queue` [priority.queue]

1

Any sequence container with random access iterator and supporting operations `front()`, `push_back()` and `pop_back()` can be used to instantiate `priority_queue`. In particular, `vector` (23.696.1) and `deque` (23.588.1) can be used. Instantiating `priority_queue` also involves supplying a function or function object for making priority comparisons; the library assumes that the function or function object defines a strict weak ordering (25.98).

```
namespace std {
  template <class T, class Container = vector<T>,
    class Compare = less<typename Container::value_type> >
  class priority_queue {
  public:
    typedef typename Container::value_type            value_type;
    typedef typename Container::reference             reference;
    typedef typename Container::const_reference       const_reference;
    typedef typename Container::size_type             size_type;
    typedef          Container                        container_type;
  protected:
    Container c;
    Compare comp;

  public:
    priority_queue(const Compare& x, const Container&);
    explicit priority_queue(const Compare& x = Compare(), Container&& = Container());
    template <class InputIterator>
      priority_queue(InputIterator first, InputIterator last,
             const Compare& x, const Container&);
    template <class InputIterator>
      priority_queue(InputIterator first, InputIterator last,
             const Compare& x = Compare(), Container&& = Container());
    template <class Alloc> explicit priority_queue(const Alloc&);
    template <class Alloc> priority_queue(const Compare&, const Alloc&);
    template <class Alloc> priority_queue(const Compare&,
      const Container&, const Alloc&);
```

```
    template <class Alloc> priority_queue(const Compare&,
      Container&&, const Alloc&);
    template <class Alloc> priority_queue(const priority_queue&, const Alloc&);
    template <class Alloc> priority_queue(priority_queue&&, const Alloc&);

    bool      empty() const       { return c.empty(); }
    size_type size()  const       { return c.size(); }
    const_reference   top() const { return c.front(); }
    void push(const value_type& x);
    void push(value_type&& x);
    template <class... Args> void emplace(Args&&... args);
    void pop();
    void swap(priority_queue& q) noexcept(
        noexcept(swap(c, q.c)) && noexcept(swap(comp, q.comp)))
      { using std::swap; swap(c, q.c); swap(comp, q.comp); }
  };
  // no equality is provided
  template <class T, class Container, class Compare>
    void swap(priority_queue<T, Container, Compare>& x,
              priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));

  template <class T, class Container, class Compare, class Alloc>
    struct uses_allocator<priority_queue<T, Container, Compare>, Alloc>
      : uses_allocator<Container, Alloc>::type { };
}
```

23.943.0.1 `priority_queue` constructors [priqueue.cons]

```
priority_queue(const Compare& x,
               const Container& y);
explicit priority_queue(const Compare& x = Compare(),
               Container&& y = Container());
```

1 *Requires:* `x` shall define a strict weak ordering (25.98).

2 *Effects:* Initializes `comp` with `x` and `c` with `y` (copy constructing or move constructing as appropriate); calls `make_heap(c.begin(), c.end(), comp)`.

```
template <class InputIterator>
  priority_queue(InputIterator first, InputIterator last,
                 const Compare& x,
                 const Container& y);
template <class InputIterator>
  priority_queue(InputIterator first, InputIterator last,
                 const Compare& x = Compare(),
                 Container&& y = Container());
```

1 *Requires:* `x` shall define a strict weak ordering (25.98).

2 *Effects:* Initializes `comp` with `x` and `c` with `y` (copy constructing or move constructing as appropriate); calls `c.insert(c.end(), first, last)`; and finally calls `make_heap(c.begin(), c.end(), comp)`.

23.945.0.1 `priority_queue` constructors with allocators [priqueue.cons.alloc]

1 If `uses_allocator<container_type, Alloc>::value` is `false` the constructors in this subclause shall not participate in overload resolution.

```
template <class Alloc>
  explicit priority_queue(const Alloc& a);
```

2 *Effects:* Initializes `c` with `a` and value-initializes `comp`.

```
template <class Alloc>
  priority_queue(const Compare& compare, const Alloc& a);
```

3 *Effects:* Initializes `c` with `a` and initializes `comp` with `compare`.

```
template <class Alloc>
  priority_queue(const Compare& compare, const Container& cont, const Alloc& a);
```

1 *Effects:* Initializes `c` with `cont` as the first argument and `a` as the second argument, and initializes `comp` with `compare`.

```
template <class Alloc>
  priority_queue(const Compare& compare, Container&& cont, const Alloc& a);
```

1 *Effects:* Initializes `c` with `std::move(cont)` as the first argument and `a` as the second argument, and initializes `comp` with `compare`.

```
template <class Alloc>
  priority_queue(const priority_queue& q, const Alloc& a);
```

2 *Effects:* Initializes `c` with `q.c` as the first argument and `a` as the second argument, and initializes `comp` with `q.comp`.

```
template <class Alloc>
  priority_queue(priority_queue&& q, const Alloc& a);
```

3 *Effects:* Initializes `c` with `std::move(q.c)` as the first argument and `a` as the second argument, and initializes `comp` with `std::move(q.comp)`.

23.947.0.1 `priority_queue` members [priqueue.members]

```
void push(const value_type& x);
```

1 *Effects:*

```
c.push_back(x);
push_heap(c.begin(), c.end(), comp);
```

```
void push(value_type&& x);
```

2 *Effects:*

```
c.push_back(std::move(x));
push_heap(c.begin(), c.end(), comp);
```

```
template <class... Args> void emplace(Args&&... args)
```

3 *Effects:*

```
c.emplace_back(std::forward<Args>(args)...);
push_heap(c.begin(), c.end(), comp);
```

```
void pop();
```

4 *Effects:*

```
pop_heap(c.begin(), c.end(), comp);
c.pop_back();
```

23.947.0.2 priority_queue specialized algorithms [priqueue.special]

```
template <class T, class Container, Compare>
  void swap(priority_queue<T, Container, Compare>& x,
            priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));
```

1 *Effects:* `x.swap(y)`.

23.947.1 Class template stack [stack]

1 Any sequence container supporting operations `back()`, `push_back()` and `pop_back()` can be used to instantiate `stack`. In particular, `vector` (23.696.1), `list` (23.672.1) and `deque` (23.588.1) can be used.

23.947.1.1 Header <stack> synopsis [stack.syn]

```
#include <initializer_list>

namespace std {

  template <class T, class Container = deque<T> > class stack;
  template <class T, class Container>
    bool operator==(const stack<T, Container>& x,const stack<T, Container>& y);
  template <class T, class Container>
    bool operator< (const stack<T, Container>& x,const stack<T, Container>& y);
  template <class T, class Container>
    bool operator!=(const stack<T, Container>& x,const stack<T, Container>& y);
  template <class T, class Container>
    bool operator> (const stack<T, Container>& x,const stack<T, Container>& y);
  template <class T, class Container>
    bool operator>=(const stack<T, Container>& x,const stack<T, Container>& y);
  template <class T, class Container>
    bool operator<=(const stack<T, Container>& x,const stack<T, Container>& y);
  template <class T, class Container>
    void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));
}
```

23.947.1.2 stack definition [stack.defn]

```
namespace std {
  template <class T, class Container = deque<T> >
  class stack {
  public:
    typedef typename Container::value_type            value_type;
    typedef typename Container::reference             reference;
    typedef typename Container::const_reference       const_reference;
    typedef typename Container::size_type             size_type;
    typedef          Container                        container_type;
  protected:
    Container c;

  public:
```

```
    explicit stack(const Container&);
    explicit stack(Container&& = Container());
    template <class Alloc> explicit stack(const Alloc&);
    template <class Alloc> stack(const Container&, const Alloc&);
    template <class Alloc> stack(Container&&, const Alloc&);
    template <class Alloc> stack(const stack&, const Alloc&);
    template <class Alloc> stack(stack&&, const Alloc&);

    bool      empty() const            { return c.empty(); }
    size_type size()  const            { return c.size(); }
    reference         top()            { return c.back(); }
    const_reference   top() const      { return c.back(); }
    void push(const value_type& x)     { c.push_back(x); }
    void push(value_type&& x)          { c.push_back(std::move(x)); }
    template <class... Args> void emplace(Args&&... args)
      { c.emplace_back(std::forward<Args>(args)...); }
    void pop()                         { c.pop_back(); }
    void swap(stack& s) noexcept(noexcept(swap(c, s.c)))
      { using std::swap; swap(c, s.c); }
  };

  template <class T, class Container>
    bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);
  template <class T, class Container>
    bool operator< (const stack<T, Container>& x, const stack<T, Container>& y);
  template <class T, class Container>
    bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);
  template <class T, class Container>
    bool operator> (const stack<T, Container>& x, const stack<T, Container>& y);
  template <class T, class Container>
    bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);
  template <class T, class Container>
    bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);
  template <class T, class Container>
    void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));

  template <class T, class Container, class Alloc>
    struct uses_allocator<stack<T, Container>, Alloc>
      : uses_allocator<Container, Alloc>::type { };
}
```

23.947.1.3 stack constructors [stack.cons]

`explicit stack(const Container& cont);`

1 *Effects:* Initializes `c` with `cont`.

`explicit stack(Container&& cont = Container());`

2 *Effects:* Initializes `c` with `std::move(cont)`.

23.947.1.4 stack constructors with allocators [stack.cons.alloc]

1 If `uses_allocator<container_type, Alloc>::value` is `false` the constructors in this subclause shall not participate in overload resolution.

```
template <class Alloc>
  explicit stack(const Alloc& a);
```

2 *Effects:* Initializes `c` with `a`.

```
template <class Alloc>
  stack(const container_type& cont, const Alloc& a);
```

3 *Effects:* Initializes `c` with `cont` as the first argument and `a` as the second argument.

```
template <class Alloc>
  stack(container_type&& cont, const Alloc& a);
```

4 *Effects:* Initializes `c` with `std::move(cont)` as the first argument and `a` as the second argument.

```
template <class Alloc>
  stack(const stack& s, const Alloc& a);
```

5 *Effects:* Initializes `c` with `s.c` as the first argument and `a` as the second argument.

```
template <class Alloc>
  stack(stack&& s, const Alloc& a);
```

6 *Effects:* Initializes `c` with `std::move(s.c)` as the first argument and `a` as the second argument.

23.947.1.5 `stack` operators [stack.ops]

```
template <class T, class Container>
    bool operator==(const stack<T, Container>& x,
                    const stack<T, Container>& y);
```

1 *Returns:* `x.c == y.c`.

```
template <class T, class Container>
    bool operator!=(const stack<T, Container>& x,
                    const stack<T, Container>& y);
```

2 *Returns:* `x.c != y.c`.

```
template <class T, class Container>
    bool operator< (const stack<T, Container>& x,
                    const stack<T, Container>& y);
```

3 *Returns:* `x.c < y.c`.

```
template <class T, class Container>
    bool operator<=(const stack<T, Container>& x,
                    const stack<T, Container>& y);
```

4 *Returns:* `x.c <= y.c`.

```
template <class T, class Container>
    bool operator> (const stack<T, Container>& x,
                    const stack<T, Container>& y);
```

5 *Returns:* `x.c > y.c`.

```
template <class T, class Container>
    bool operator>=(const stack<T, Container>& x,
                    const stack<T, Container>& y);
```

6 *Returns:* `x.c >= y.c`.

23.947.1.6 stack specialized algorithms [stack.special]

```
template <class T, class Container>
  void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));
```

1 *Effects:* `x.swap(y)`.

24 Iterators library [iterators]

24.1 General [iterators.general]

1 This Clause describes components that C++ programs may use to perform iterations over containers (Clause 23), streams (27.109), and stream buffers (27.92).

2 The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators, and stream iterators, as summarized in Table 104.

Table 104 — Iterators library summary

	Subclause	Header(s)
24.2	Requirements	
24.172	Iterator primitives	`<iterator>`
24.197	Predefined iterators	
24.207	Stream iterators	

24.2 Iterator requirements [iterator.requirements]

24.2.1 In general [iterator.requirements.general]

1

Iterators are a generalization of pointers that allow a C++ program to work with different data structures (containers) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterators. All input iterators `i` support the expression `*i`, resulting in a value of some object type `T`, called the *value type* of the iterator. All output iterators support the expression `*i = o` where `o` is a value of some type that is in the set of types that are *writable* to the particular iterator type of `i`. All iterators `i` for which the expression `(*i).m` is well-defined, support the expression `i->m` with the same semantics as `(*i).m`. For every iterator type `X` for which equality is defined, there is a corresponding signed integer type called the *difference type* of the iterator.

1

Since iterators are an abstraction of pointers, their semantics is a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This International Standard defines five categories of iterators, according to the operations defined on them: *input iterators*, *output iterators*, *forward iterators*, *bidirectional iterators* and *random access iterators*, as shown in Table 105.

Table 105 — Relations among iterator categories

Random Access	→ **Bidirectional**	→ **Forward**	→ **Input**
			→ **Output**

1

Forward iterators satisfy all the requirements of input iterators and can be used whenever an input iterator is specified; Bidirectional iterators also satisfy all the requirements of forward iterators and can be used whenever a forward iterator is specified; Random access iterators also satisfy all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified.

1

Iterators that further satisfy the requirements of output iterators are called *mutable iterator*s. Nonmutable iterators are referred to as *constant iterator*s.

1

Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type there is an iterator value that points past the last element of a corresponding sequence. These values are called *past-the-end* values. Values of an iterator `i` for which the expression `*i` is defined are called *dereferenceable*. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any sequence. [*Example:* After the declaration of an uninitialized pointer `x` (as with `int* x;`), `x` must always be assumed to have a singular value of a pointer. — *end example*] Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value, the assignment of a non-singular value to an iterator that holds a singular value, and, for iterators that satisfy the `DefaultConstructible` requirements, using a value-initialized iterator as the source of a copy or move operation. [*Note:* This guarantee is not offered for default initialization, although the distinction only matters for types with trivial default constructors such as pointers or aggregates holding pointers. — *end note*] In these cases the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.

1

An iterator `j` is called *reachable* from an iterator `i` if and only if there is a finite sequence of applications of the expression `++i` that makes `i == j`. If `j` is reachable from `i`, they refer to elements of the same sequence.

1

Most of the library's algorithmic templates that operate on data structures have interfaces that use ranges. A *range* is a pair of iterators that designate the beginning and end of the computation. A range `[i,i)` is an empty range; in general, a range `[i,j)` refers to the elements in the data structure starting with the element pointed to by `i` and up to but not including the element pointed to by `j`. Range `[i,j)` is valid if and only if `j` is reachable from `i`. The result of the application of functions in the library to invalid ranges is undefined.

1

All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables for the iterators do not have a complexity column.

1

Destruction of an iterator may invalidate pointers and references previously obtained from that iterator.

1

An *invalid* iterator is an iterator that may be singular.[267]

1

In the following sections, `a` and `b` denote values of type `X` or `const X`, `difference_type` and `reference` refer to the types `iterator_traits<X>::difference_type` and `iterator_traits<X>::reference`, respectively, `n` denotes a value of `difference_type`, `u`, `tmp`, and `m` denote identifiers, `r` denotes a value of `X&`, `t` denotes a value of value type `T`, `o` denotes a value of some type that is writable to the output iterator. [*Note:* For an iterator type `X` there must be an instantiation of `iterator_traits<X>` (24.172.1). — *end note*]

24.95.1 Iterator [iterator.iterators]

1

267) This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.

The `Iterator` requirements form the basis of the iterator concept taxonomy; every iterator satisfies the `Iterator` requirements. This set of requirements specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to read (24.100.1) or write (24.116.1) values, or to provide a richer set of iterator movements (24.122.1, 24.165.1, 24.167.1).)

1

A type `X` satisfies the `Iterator` requirements if:

— `X` satisfies the `CopyConstructible`, `CopyAssignable`, and `Destructible` requirements (17.128.1.1) and lvalues of type `X` are swappable (17.143.0.1), and

— the expressions in Table 106 are valid and have the indicated semantics.

Table 106 — Iterator requirements

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`*r`	`reference`		pre: `r` is dereferenceable.
`++r`	`X&`		

24.100.1 Input iterators [input.iterators]

1

A class or pointer type `X` satisfies the requirements of an input iterator for the value type `T` if X satisfies the `Iterator` (24.95.1) and `EqualityComparable` (Table 17) requirements and the expressions in Table 107 are valid and have the indicated semantics.

1

In Table 107, the term *the domain of* `==` is used in the ordinary mathematical sense to denote the set of values over which `==` is (required to be) defined. This set can change over time. Each algorithm places additional requirements on the domain of `==` for the iterator values it uses. These requirements can be inferred from the uses that algorithm makes of `==` and `!=`. [*Example:* the call `find(a,b,x)` is defined only if the value of `a` has the property p defined as follows: `b` has property p and a value `i` has property p if `(*i==x)` or if `(*i!=x` and `++i` has property `p`). — *end example*]

Table 107 — Input iterator requirements (in addition to Iterator)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`a != b`	contextually convertible to `bool`	`!(a == b)`	pre: `(a,b)` is in the domain of `==`.
`*a`	convertible to `T`		pre: `a` is dereferenceable. The expression `(void)*a, *a` is equivalent to `*a`. If `a == b` and `(a,b)` is in the domain of `==` then `*a` is equivalent to `*b`.
`a->m`		`(*a).m`	pre: `a` is dereferenceable.

Table 107 — Input iterator requirements (in addition to Iterator) (continued)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`++r`	`X&`		pre: `r` is dereferenceable. post: `r` is dereferenceable or `r` is past-the-end. post: any copies of the previous value of `r` are no longer required either to be dereferenceable or to be in the domain of `==`.
`(void)r++`			equivalent to `(void)++r`
`*r++`	convertible to `T`	`{ T tmp = *r; ++r; return tmp; }`	

1

[*Note:* For input iterators, `a == b` does not imply `++a == ++b`. (Equality does not guarantee the substitution property or referential transparency.) Algorithms on input iterators should never attempt to pass through the same iterator twice. They should be *single pass* algorithms. Value type T is not required to be a `CopyAssignable` type (Table 23). These algorithms can be used with istreams as the source of the input data through the `istream_iterator` class template. — *end note*]

24.116.1 Output iterators [output.iterators]

1

A class or pointer type `X` satisfies the requirements of an output iterator if `X` satisfies the `Iterator` requirements (24.95.1) and the expressions in Table 108 are valid and have the indicated semantics.

Table 108 — Output iterator requirements (in addition to Iterator)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`*r = o`	result is not used		*Remark:* After this operation `r` is not required to be dereferenceable. post: `r` is incrementable.
`++r`	`X&`		`&r == &++r`. *Remark:* After this operation `r` is not required to be dereferenceable. post: `r` is incrementable.
`r++`	convertible to `const X&`	`{ X tmp = r; ++r; return tmp; }`	*Remark:* After this operation `r` is not required to be dereferenceable. post: `r` is incrementable.

Table 108 — Output iterator requirements (in addition to Iterator) (continued)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`*r++ = o`	result is not used		*Remark:* After this operation `r` is not required to be dereferenceable. post: `r` is incrementable.

1

[*Note:* The only valid use of an `operator*` is on the left side of the assignment statement. *Assignment through the same value of the iterator happens only once.* Algorithms on output iterators should never attempt to pass through the same iterator twice. They should be *single pass* algorithms. Equality and inequality might not be defined. Algorithms that take output iterators can be used with ostreams as the destination for placing data through the `ostream_iterator` class as well as with insert iterators and insert pointers. — *end note*]

24.122.1 Forward iterators [forward.iterators]

1

A class or pointer type `X` satisfies the requirements of a forward iterator if

— `X` satisfies the requirements of an input iterator (24.100.1),

— X satisfies the `DefaultConstructible` requirements (17.128.1.1),

— if `X` is a mutable iterator, `reference` is a reference to `T`; if `X` is a const iterator, `reference` is a reference to `const T`,

— the expressions in Table 109 are valid and have the indicated semantics, and

— objects of type `X` offer the multi-pass guarantee, described below.

1

The domain of == for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators may be compared and shall compare equal to other value-initialized iterators of the same type. [*Note:* value initialized iterators behave as if they refer past the end of the same empty sequence — *end note*]

1

Two dereferenceable iterators `a` and `b` of type `X` offer the *multi-pass guarantee* if:

— `a == b` implies `++a == ++b` and

— `X` is a pointer type or the expression `(void)++X(a), *a` is equivalent to the expression `*a`.

1

[*Note:* The requirement that `a == b` implies `++a == ++b` (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through a mutable iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators. — *end note*]

Table 109 — Forward iterator requirements (in addition to input iterator)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition

`r++`	convertible to `const X&`	`{ X tmp = r;`
		`++r;`
		`return tmp; }`	

`*r++`	`reference`		

1

If `a` and `b` are equal, then either `a` and `b` are both dereferenceable or else neither is dereferenceable.

1

If `a` and `b` are both dereferenceable, then `a == b` if and only if `*a` and `*b` are bound to the same object.

24.165.1 Bidirectional iterators [bidirectional.iterators]

1

A class or pointer type `X` satisfies the requirements of a bidirectional iterator if, in addition to satisfying the requirements for forward iterators, the following expressions are valid as shown in Table 110.

Table 110 — Bidirectional iterator requirements (in addition to forward iterator)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`--r`	`X&`		pre: there exists `s` such that `r == ++s`. post: `r` is dereferenceable. `--(++r) == r`. `--r == --s` implies `r == s`. `&r == &--r`.

`r--`	convertible to `const X&`	`{ X tmp = r;`
		`--r;`
		`return tmp; }`	

`*r--`	`reference`		

1 [*Note:* Bidirectional iterators allow algorithms to move iterators backward as well as forward. — *end note*]

24.167.1 Random access iterators [random.access.iterators]

1

A class or pointer type `X` satisfies the requirements of a random access iterator if, in addition to satisfying the requirements for bidirectional iterators, the following expressions are valid as shown in Table 111.

Table 111 — Random access iterator requirements (in addition to bidirectional iterator)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition

`r += n`	`X&`	`{ difference_type m = n;`
		`if (m >= 0)`
		`while (m--)`
		`++r;`
		`else`
		`while (m++)`
		`--r;`
		`return r; }`	

`a + n` `n + a`	`X`	`{ X tmp = a;` `return tmp += n; }`	`a + n == n + a`.
`r -= n`	`X&`	`return r += -n;`	
`a - n`	`X`	`{ X tmp = a;` `return tmp -= n; }`	
`b - a`	`difference_type`	`return n`	pre: there exists a value `n` of type `difference_type` such that `a + n == b`. `b == a + (b - a)`.
`a[n]`	convertible to `reference`	`*(a + n)`	
`a < b`	contextually convertible to `bool`	`b - a > 0`	`<` is a total ordering relation
`a > b`	contextually convertible to `bool`	`b < a`	`>` is a total ordering relation opposite to `<`.
`a >= b`	contextually convertible to `bool`	`!(a < b)`	
`a <= b`	contextually convertible to `bool`.	`!(a > b)`	

24.171 Header `<iterator>` synopsis [iterator.synopsis]

```

}
```

24.172 Iterator primitives [iterator.primitives]

1 To simplify the task of defining iterators, the library provides several classes and functions:

24.172.1 Iterator traits [iterator.traits]

1

To implement algorithms only in terms of iterators, it is often necessary to determine the value and difference types that correspond to a particular iterator type. Accordingly, it is required that if `Iterator` is the type of an iterator, the types

```
iterator_traits<Iterator>::difference_type
iterator_traits<Iterator>::value_type
iterator_traits<Iterator>::iterator_category
```

be defined as the iterator's difference type, value type and iterator category, respectively. In addition, the types

```
iterator_traits<Iterator>::reference
iterator_traits<Iterator>::pointer
```

shall be defined as the iterator's reference and pointer types, that is, for an iterator object `a`, the same type as the type of `*a` and `a->`, respectively. In the case of an output iterator, the types

```
iterator_traits<Iterator>::difference_type
iterator_traits<Iterator>::value_type
iterator_traits<Iterator>::reference
iterator_traits<Iterator>::pointer
```

may be defined as `void`.

1 The template `iterator_traits<Iterator>` is defined as

```
namespace std {
  template<class Iterator> struct iterator_traits {
    typedef typename Iterator::difference_type difference_type;
    typedef typename Iterator::value_type value_type;
    typedef typename Iterator::pointer pointer;
    typedef typename Iterator::reference reference;
    typedef typename Iterator::iterator_category iterator_category;
  };
}
```

2 It is specialized for pointers as

```
namespace std {
  template<class T> struct iterator_traits<T*> {
    typedef ptrdiff_t difference_type;
    typedef T value_type;
    typedef T* pointer;
    typedef T& reference;
    typedef random_access_iterator_tag iterator_category;
  };
}
```

and for pointers to const as

```
namespace std {
  template<class T> struct iterator_traits<const T*> {
    typedef ptrdiff_t difference_type;
    typedef T value_type;
    typedef const T* pointer;
    typedef const T& reference;
    typedef random_access_iterator_tag iterator_category;
  };
}
```

3 [*Example:* To implement a generic `reverse` function, a C++ program can do the following:

```
template <class BidirectionalIterator>
void reverse(BidirectionalIterator first, BidirectionalIterator last) {
  typename iterator_traits<BidirectionalIterator>::difference_type n =
    distance(first, last);
  --n;
  while(n > 0) {
    typename iterator_traits<BidirectionalIterator>::value_type
     tmp = *first;
    *first++ = *--last;
    *last = tmp;
```

```
    n -= 2;
  }
}
```

— *end example*]

24.182.1 Basic iterator [iterator.basic]

1

The `iterator` template may be used as a base class to ease the definition of required types for new iterators.

```
namespace std {
  template<class Category, class T, class Distance = ptrdiff_t,
    class Pointer = T*, class Reference = T&>
  struct iterator {
    typedef T         value_type;
    typedef Distance  difference_type;
    typedef Pointer   pointer;
    typedef Reference reference;
    typedef Category  iterator_category;
  };
}
```

24.183.1 Standard iterator tags [std.iterator.tags]

1

It is often desirable for a function template specialization to find out what is the most specific category of its iterator argument, so that the function can select the most efficient algorithm at compile time. To facilitate this, the library introduces *category tag* classes which are used as compile time tags for algorithm selection. They are: `input_iterator_tag`, `output_iterator_tag`, `forward_iterator_tag`, `bidirectional_iterator_tag` and `random_access_iterator_tag`. For every iterator of type `Iterator`, `iterator_traits<Iterator>::iterator_category` shall be defined to be the most specific category tag that describes the iterator's behavior.

```
namespace std {
  struct input_iterator_tag { };
  struct output_iterator_tag { };
  struct forward_iterator_tag: public input_iterator_tag { };
  struct bidirectional_iterator_tag: public forward_iterator_tag { };
  struct random_access_iterator_tag: public bidirectional_iterator_tag { };
}
```

1 [*Example:* For a program-defined iterator `BinaryTreeIterator`, it could be included into the bidirectional iterator category by specializing the `iterator_traits` template:

```
template<class T> struct iterator_traits<BinaryTreeIterator<T> > {
  typedef std::ptrdiff_t difference_type;
  typedef T value_type;
  typedef T* pointer;
  typedef T& reference;
  typedef bidirectional_iterator_tag iterator_category;
};
```

Typically, however, it would be easier to derive `BinaryTreeIterator<T>` from `iterator<bidirectional_iterator_tag,T,ptrdiff_t,T*,T&>`. — *end example*]

2 [*Example:* If `evolve()` is well defined for bidirectional iterators, but can be implemented more efficiently for random access iterators, then the implementation is as follows:

```
template <class BidirectionalIterator>
inline void
evolve(BidirectionalIterator first, BidirectionalIterator last) {
  evolve(first, last,
    typename iterator_traits<BidirectionalIterator>::iterator_category());
}

template <class BidirectionalIterator>
void evolve(BidirectionalIterator first, BidirectionalIterator last,
  bidirectional_iterator_tag) {
  // more generic, but less efficient algorithm
}

template <class RandomAccessIterator>
void evolve(RandomAccessIterator first, RandomAccessIterator last,
  random_access_iterator_tag) {
  // more efficient, but less generic algorithm
}
```

— *end example*]

3 [*Example:* If a C++ program wants to define a bidirectional iterator for some data structure containing `double` and such that it works on a large memory model of the implementation, it can do so with:

```
class MyIterator :
  public iterator<bidirectional_iterator_tag, double, long, T*, T&> {
  // code implementing ++, etc.
};
```

4 Then there is no need to specialize the `iterator_traits` template. — *end example*]

24.185.1 Iterator operations [iterator.operations]

1

Since only random access iterators provide `+` and `-` operators, the library provides two function templates `advance` and `distance`. These function templates use `+` and `-` for random access iterators (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use `++` to provide linear time implementations.

```
template <class InputIterator, class Distance>
  void advance(InputIterator& i, Distance n);
```

1

Requires: `n` shall be negative only for bidirectional and random access iterators.

1

Effects: Increments (or decrements for negative `n`) iterator reference `i` by `n`.

```
template<class InputIterator>
    typename iterator_traits<InputIterator>::difference_type
       distance(InputIterator first, InputIterator last);
```

1 *Effects:* If `InputIterator` meets the requirements of random access iterator, returns `(last - first)`; otherwise, returns the number of increments needed to get from `first` to `last`.

2

Requires: If `InputIterator` meets the requirements of random access iterator, `last` shall be reachable from `first` or `first` shall be reachable from `last`; otherwise, `last` shall be reachable from `first`.

```
template <class ForwardIterator>
  ForwardIterator next(ForwardIterator x,
    typename std::iterator_traits<ForwardIterator>::difference_type n = 1);
```

1 *Effects:* Equivalent to `advance(x, n); return x;`

```
template <class BidirectionalIterator>
  BidirectionalIterator prev(BidirectionalIterator x,
    typename std::iterator_traits<BidirectionalIterator>::difference_type n = 1);
```

2 *Effects:* Equivalent to `advance(x, -n); return x;`

24.197 Iterator adaptors [predef.iterators]

24.197.1 Reverse iterators [reverse.iterators]

1

Class template `reverse_iterator` is an iterator adaptor that iterates from the end of the sequence defined by its underlying iterator to the beginning of that sequence. The fundamental relation between a reverse iterator and its corresponding iterator `i` is established by the identity: `&*(reverse_iterator(i)) == &*(i - 1)`.

24.203.0.1 Class template `reverse_iterator` [reverse.iterator]

```
namespace std {
  template <class Iterator>
  class reverse_iterator : public
        iterator<typename iterator_traits<Iterator>::iterator_category,
        typename iterator_traits<Iterator>::value_type,
        typename iterator_traits<Iterator>::difference_type,
        typename iterator_traits<Iterator>::pointer,
        typename iterator_traits<Iterator>::reference> {
  public:
    typedef Iterator                                          iterator_type;
    typedef typename iterator_traits<Iterator>::difference_type difference_type;
    typedef typename iterator_traits<Iterator>::reference       reference;
    typedef typename iterator_traits<Iterator>::pointer         pointer;

    reverse_iterator();
    explicit reverse_iterator(Iterator x);
    template <class U> reverse_iterator(const reverse_iterator<U>& u);
    template <class U> reverse_iterator& operator=(const reverse_iterator<U>& u);

    Iterator base() const;      // explicit
    reference operator*() const;
    pointer   operator->() const;

    reverse_iterator& operator++();
    reverse_iterator  operator++(int);
    reverse_iterator& operator--();
    reverse_iterator  operator--(int);

    reverse_iterator  operator+ (difference_type n) const;
```

```
    reverse_iterator& operator+=(difference_type n);
    reverse_iterator  operator- (difference_type n) const;
    reverse_iterator& operator-=(difference_type n);
    unspecified  operator[](difference_type n) const;
  protected:
    Iterator current;
  };

  template <class Iterator1, class Iterator2>
    bool operator==(
      const reverse_iterator<Iterator1>& x,
      const reverse_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    bool operator<(
      const reverse_iterator<Iterator1>& x,
      const reverse_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    bool operator!=(
      const reverse_iterator<Iterator1>& x,
      const reverse_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    bool operator>(
      const reverse_iterator<Iterator1>& x,
      const reverse_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    bool operator>=(
      const reverse_iterator<Iterator1>& x,
      const reverse_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    bool operator<=(
      const reverse_iterator<Iterator1>& x,
      const reverse_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    auto operator-(
      const reverse_iterator<Iterator1>& x,
      const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());
  template <class Iterator>
    reverse_iterator<Iterator> operator+(
      typename reverse_iterator<Iterator>::difference_type n,
      const reverse_iterator<Iterator>& x);

  template <class Iterator>
    reverse_iterator<Iterator> make_reverse_iterator(Iterator i);
}
```

24.203.0.2 `reverse_iterator` requirements [reverse.iter.requirements]

1 The template parameter `Iterator` shall meet all the requirements of a Bidirectional Iterator (24.165.1).

2 Additionally, `Iterator` shall meet the requirements of a Random Access Iterator (24.167.1) if any of the members `operator+` (24.203.0.3.8), `operator-` (24.203.0.3.10), `operator+=` (24.203.0.3.9), `operator-=` (24.203.0.3.11), `operator []` (24.203.0.3.12), or the global operators `operator<` (24.203.0.3.14), `operator>` (24.203.0.3.16), `operator <=` (24.203.0.3.18), `operator>=` (24.203.0.3.17), `operator-` (24.203.0.3.19) or `operator+` (24.203.0.3.20) are referenced in a way that requires instantiation (14.1644.1).

24.203.0.3 `reverse_iterator` operations [reverse.iter.ops]

24.203.0.3.1 `reverse_iterator` constructor [reverse.iter.cons]

```
reverse_iterator();
```

1 *Effects:* Value initializes `current`. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a value-initialized iterator of type `Iterator`.

```
explicit reverse_iterator(Iterator x);
```

2 *Effects:* Initializes `current` with `x`.

```
template <class U> reverse_iterator(const reverse_iterator<U> &u);
```

3 *Effects:* Initializes `current` with `u.current`.

24.203.0.3.2 `reverse_iterator::operator=` [reverse.iter.op=]

```
template <class U>
reverse_iterator&
  operator=(const reverse_iterator<U>& u);
```

1 *Effects:* Assigns `u.base()` to current.

2 *Returns:* `*this`.

24.203.0.3.3 Conversion [reverse.iter.conv]

```
Iterator base() const;          // explicit
```

1 *Returns:* `current`.

24.203.0.3.4 `operator*` [reverse.iter.op.star]

```
reference operator*() const;
```

1 *Effects:*

```
Iterator tmp = current;
return *--tmp;
```

24.203.0.3.5 `operator->` [reverse.iter.opref]

```
pointer operator->() const;
```

1 *Returns:* `std::addressof(operator*())`.

24.203.0.3.6 `operator++` [reverse.iter.op++]

```
reverse_iterator& operator++();
```

1 *Effects:* `--current;`

2 *Returns:* `*this`.

```
reverse_iterator operator++(int);
```

3 *Effects:*

```
reverse_iterator tmp = *this;
--current;
return tmp;
```

24.203.0.3.7 `operator--` [reverse.iter.op--]

```
reverse_iterator& operator--();
```

1 *Effects:* `++current`

2 *Returns:* `*this`.

```
reverse_iterator operator--(int);
```

3 *Effects:*

```
reverse_iterator tmp = *this;
++current;
return tmp;
```

24.203.0.3.8 `operator+` [reverse.iter.op+]

```
reverse_iterator
operator+(typename reverse_iterator<Iterator>::difference_type n) const;
```

1 *Returns:* `reverse_iterator(current-n)`.

24.203.0.3.9 `operator+=` [reverse.iter.op+=]

```
reverse_iterator&
operator+=(typename reverse_iterator<Iterator>::difference_type n);
```

1 *Effects:* `current -= n;`

2 *Returns:* `*this`.

24.203.0.3.10 `operator-` [reverse.iter.op-]

```
reverse_iterator
operator-(typename reverse_iterator<Iterator>::difference_type n) const;
```

1 *Returns:* `reverse_iterator(current+n)`.

24.203.0.3.11 `operator-=` [reverse.iter.op-=]

```
reverse_iterator&
operator-=(typename reverse_iterator<Iterator>::difference_type n);
```

1 *Effects:* `current += n;`

2 *Returns:* `*this`.

24.203.0.3.12 `operator[]` [reverse.iter.opindex]

```
unspecified  operator[](
    typename reverse_iterator<Iterator>::difference_type n) const;
```

1 *Returns:* `current[-n-1]`.

24.203.0.3.13 `operator==` [reverse.iter.op==]

```
template <class Iterator1, class Iterator2>
  bool operator==(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

1 *Returns:* `x.current == y.current`.

24.203.0.3.14 `operator<` [reverse.iter.op<]

```
template <class Iterator1, class Iterator2>
  bool operator<(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

1 *Returns:* `x.current > y.current`.

24.203.0.3.15 `operator!=` [reverse.iter.op!=]

```
template <class Iterator1, class Iterator2>
  bool operator!=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

1 *Returns:* `x.current != y.current`.

24.203.0.3.16 `operator>` [reverse.iter.op>]

```
template <class Iterator1, class Iterator2>
  bool operator>(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

1 *Returns:* `x.current < y.current`.

24.203.0.3.17 `operator>=` [reverse.iter.op>=]

```
template <class Iterator1, class Iterator2>
  bool operator>=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

1 *Returns:* `x.current <= y.current`.

24.203.0.3.18 `operator<=` [reverse.iter.op<=]

```
template <class Iterator1, class Iterator2>
  bool operator<=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

1 *Returns:* `x.current >= y.current`.

24.203.0.3.19 `operator-` [reverse.iter.opdiff]

```
template <class Iterator1, class Iterator2>
    auto operator-(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());
```

1 *Returns:* `y.current - x.current`.

24.203.0.3.20 `operator+` [reverse.iter.opsum]

```
template <class Iterator>
  reverse_iterator<Iterator> operator+(
    typename reverse_iterator<Iterator>::difference_type n,
    const reverse_iterator<Iterator>& x);
```

1 *Returns:* `reverse_iterator<Iterator> (x.current - n)`.

24.203.0.3.21 Non-member function `make_reverse_iterator()` [reverse.iter.make]

```
template <class Iterator>
  reverse_iterator<Iterator> make_reverse_iterator(Iterator i);
```

1 *Returns:* `reverse_iterator<Iterator>(i)`.

24.203.1 Insert iterators [insert.iterators]

1 To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called *insert iterators*, are provided in the library. With regular iterator classes,

```
while (first != last) *result++ = *first++;
```

causes a range `[first,last)` to be copied into a range starting with result. The same code with `result` being an insert iterator will insert corresponding elements into the container. This device allows all of the copying algorithms in the library to work in the *insert mode* instead of the *regular overwrite* mode.

2

An insert iterator is constructed from a container and possibly one of its iterators pointing to where insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators satisfy the requirements of output iterators. `operator*` returns the insert iterator itself. The assignment `operator=(const T& x)` is defined on insert iterators to allow writing into them, it inserts `x` right before where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the container where the insertion takes place. `back_insert_iterator` inserts elements at the end of a container, `front_insert_iterator` inserts elements at the beginning of a container, and `insert_iterator` inserts elements where the iterator points to in a container. `back_inserter`, `front_inserter`, and `inserter` are three functions making the insert iterators out of a container.

24.205.0.1 Class template `back_insert_iterator` [back.insert.iterator]

```
namespace std {
  template <class Container>
  class back_insert_iterator :
    public iterator<output_iterator_tag,void,void,void,void> {
  protected:
    Container* container;

  public:
    typedef Container container_type;
    explicit back_insert_iterator(Container& x);
    back_insert_iterator<Container>&
      operator=(const typename Container::value_type& value);
    back_insert_iterator<Container>&
      operator=(typename Container::value_type&& value);

    back_insert_iterator<Container>& operator*();
    back_insert_iterator<Container>& operator++();
    back_insert_iterator<Container>  operator++(int);
  };

  template <class Container>
    back_insert_iterator<Container> back_inserter(Container& x);
}
```

24.205.0.2 `back_insert_iterator` operations [back.insert.iter.ops]

24.205.0.2.1 `back_insert_iterator` constructor [back.insert.iter.cons]

```
explicit back_insert_iterator(Container& x);
```

1 *Effects:* Initializes `container` with `std::addressof(x)`.

24.205.0.2.2 `back_insert_iterator::operator=` [back.insert.iter.op=]

```
back_insert_iterator<Container>&
  operator=(const typename Container::value_type& value);
```

1 *Effects:* `container->push_back(value);`

2 *Returns:* `*this`.

```
back_insert_iterator<Container>&
  operator=(typename Container::value_type&& value);
```

3 *Effects:* `container->push_back(std::move(value));`

4 *Returns:* `*this`.

24.205.0.2.3 `back_insert_iterator::operator*` [back.insert.iter.op*]

```
back_insert_iterator<Container>& operator*();
```

1 *Returns:* `*this`.

24.205.0.2.4 `back_insert_iterator::operator++` [back.insert.iter.op++]

```
back_insert_iterator<Container>& operator++();
back_insert_iterator<Container>  operator++(int);
```

1 *Returns:* `*this`.

24.205.0.2.5 `back_inserter` [back.inserter]

```
template <class Container>
  back_insert_iterator<Container> back_inserter(Container& x);
```

1 *Returns:* `back_insert_iterator<Container>(x)`.

24.205.0.3 Class template `front_insert_iterator` [front.insert.iterator]

```
namespace std {
  template <class Container>
  class front_insert_iterator :
    public iterator<output_iterator_tag,void,void,void,void> {
  protected:
    Container* container;

  public:
    typedef Container container_type;
    explicit front_insert_iterator(Container& x);
    front_insert_iterator<Container>&
      operator=(const typename Container::value_type& value);
    front_insert_iterator<Container>&
      operator=(typename Container::value_type&& value);

    front_insert_iterator<Container>& operator*();
    front_insert_iterator<Container>& operator++();
    front_insert_iterator<Container>  operator++(int);
  };
```

```
  template <class Container>
    front_insert_iterator<Container> front_inserter(Container& x);
}
```

24.205.0.4 `front_insert_iterator` operations [front.insert.iter.ops]

24.205.0.4.1 `front_insert_iterator` constructor [front.insert.iter.cons]

```
explicit front_insert_iterator(Container& x);
```

1 *Effects:* Initializes `container` with `std::addressof(x)`.

24.205.0.4.2 `front_insert_iterator::operator=` [front.insert.iter.op=]

```
front_insert_iterator<Container>&
  operator=(const typename Container::value_type& value);
```

1 *Effects:* `container->push_front(value);`

2 *Returns:* `*this`.

```
front_insert_iterator<Container>&
  operator=(typename Container::value_type&& value);
```

3 *Effects:* `container->push_front(std::move(value));`

4 *Returns:* `*this`.

24.205.0.4.3 `front_insert_iterator::operator*` [front.insert.iter.op*]

```
front_insert_iterator<Container>& operator*();
```

1 *Returns:* `*this`.

24.205.0.4.4 `front_insert_iterator::operator++` [front.insert.iter.op++]

```
front_insert_iterator<Container>& operator++();
front_insert_iterator<Container>  operator++(int);
```

1 *Returns:* `*this`.

24.205.0.4.5 `front_inserter` [front.inserter]

```
template <class Container>
  front_insert_iterator<Container> front_inserter(Container& x);
```

1 *Returns:* `front_insert_iterator<Container>(x)`.

24.205.0.5 Class template `insert_iterator` [insert.iterator]

```
namespace std {
  template <class Container>
  class insert_iterator :
    public iterator<output_iterator_tag,void,void,void,void> {
  protected:
    Container* container;
    typename Container::iterator iter;

  public:
    typedef Container container_type;
    insert_iterator(Container& x, typename Container::iterator i);
    insert_iterator<Container>&
      operator=(const typename Container::value_type& value);
```

```
    insert_iterator<Container>&
      operator=(typename Container::value_type&& value);

    insert_iterator<Container>& operator*();
    insert_iterator<Container>& operator++();
    insert_iterator<Container>& operator++(int);
  };

  template <class Container>
    insert_iterator<Container> inserter(Container& x, typename Container::iterator i);
}
```

24.205.0.6 insert_iterator operations [insert.iter.ops]

24.205.0.6.1 insert_iterator constructor [insert.iter.cons]

```
insert_iterator(Container& x, typename Container::iterator i);
```

1 *Effects:* Initializes `container` with `std::addressof(x)` and `iter` with `i`.

24.205.0.6.2 insert_iterator::operator= [insert.iter.op=]

```
insert_iterator<Container>&
  operator=(const typename Container::value_type& value);
```

1 *Effects:*

```
iter = container->insert(iter, value);
++iter;
```

2 *Returns:* `*this`.

```
insert_iterator<Container>&
  operator=(typename Container::value_type&& value);
```

3 *Effects:*

```
iter = container->insert(iter, std::move(value));
++iter;
```

4 *Returns:* `*this`.

24.205.0.6.3 insert_iterator::operator* [insert.iter.op*]

```
insert_iterator<Container>& operator*();
```

1 *Returns:* `*this`.

24.205.0.6.4 insert_iterator::operator++ [insert.iter.op++]

```
insert_iterator<Container>& operator++();
insert_iterator<Container>& operator++(int);
```

1 *Returns:* `*this`.

24.205.0.6.5 inserter [inserter]

```
template <class Container>
  insert_iterator<Container> inserter(Container& x, typename Container::iterator i);
```

1 *Returns:* `insert_iterator<Container>(x, i)`.

24.205.1 Move iterators [move.iterators]

1

Class template `move_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator's indirection operator to an rvalue reference. Some generic algorithms can be called with move iterators to replace copying with moving.

1 [*Example:*

```
list<string> s;
// populate the list s
vector<string> v1(s.begin(), s.end());          // copies strings into v1
vector<string> v2(make_move_iterator(s.begin()),
                  make_move_iterator(s.end())); // moves strings into v2
```

— *end example*]

24.206.0.1 Class template `move_iterator` [move.iterator]

```
namespace std {
  template <class Iterator>
  class move_iterator {
  public:
    typedef Iterator                                              iterator_type;
    typedef typename iterator_traits<Iterator>::difference_type   difference_type;
    typedef Iterator                                              pointer;
    typedef typename iterator_traits<Iterator>::value_type        value_type;
    typedef typename iterator_traits<Iterator>::iterator_category iterator_category;
    typedef value_type&&                                          reference;

    move_iterator();
    explicit move_iterator(Iterator i);
    template <class U> move_iterator(const move_iterator<U>& u);
    template <class U> move_iterator& operator=(const move_iterator<U>& u);

    iterator_type base() const;
    reference operator*() const;
    pointer operator->() const;

    move_iterator& operator++();
    move_iterator operator++(int);
    move_iterator& operator--();
    move_iterator operator--(int);

    move_iterator operator+(difference_type n) const;
    move_iterator& operator+=(difference_type n);
    move_iterator operator-(difference_type n) const;
    move_iterator& operator-=(difference_type n);
    unspecified  operator[](difference_type n) const;

  private:
    Iterator current;    // exposition only
  };

  template <class Iterator1, class Iterator2>
    bool operator==(
```

```
      const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    bool operator!=(
      const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    bool operator<(
      const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    bool operator<=(
      const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    bool operator>(
      const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
  template <class Iterator1, class Iterator2>
    bool operator>=(
      const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

  template <class Iterator1, class Iterator2>
    auto operator-(
      const move_iterator<Iterator1>& x,
      const move_iterator<Iterator2>& y) -> decltype(x.base() - y.base());
  template <class Iterator>
    move_iterator<Iterator> operator+(
      typename move_iterator<Iterator>::difference_type n, const move_iterator<Iterator>& x);
  template <class Iterator>
    move_iterator<Iterator> make_move_iterator(Iterator i);
}
```

24.206.0.2 `move_iterator` requirements [move.iter.requirements]

1 The template parameter `Iterator` shall meet the requirements for an Input Iterator (24.100.1). Additionally, if any of the bidirectional or random access traversal functions are instantiated, the template parameter shall meet the requirements for a Bidirectional Iterator (24.165.1) or a Random Access Iterator (24.167.1), respectively.

24.206.0.3 `move_iterator` operations [move.iter.ops]

24.206.0.3.1 `move_iterator` constructors [move.iter.op.const]

```
move_iterator();
```

1 *Effects:* Constructs a `move_iterator`, value initializing `current`. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a value-initialized iterator of type `Iterator`.

```
explicit move_iterator(Iterator i);
```

2 *Effects:* Constructs a `move_iterator`, initializing `current` with `i`.

```
template <class U> move_iterator(const move_iterator<U>& u);
```

3 *Effects:* Constructs a `move_iterator`, initializing `current` with `u.base()`.

4 *Requires:* `U` shall be convertible to `Iterator`.

24.206.0.3.2 `move_iterator::operator=` [move.iter.op=]

```
template <class U> move_iterator& operator=(const move_iterator<U>& u);
```

1 *Effects:* Assigns `u.base()` to `current`.

2 *Requires:* `U` shall be convertible to `Iterator`.

24.206.0.3.3 `move_iterator` conversion [move.iter.op.conv]

```
Iterator base() const;
```

1 *Returns:* `current`.

24.206.0.3.4 `move_iterator::operator*` [move.iter.op.star]

```
reference operator*() const;
```

1 *Returns:* `std::move(`*current).

24.206.0.3.5 `move_iterator::operator->` [move.iter.op.ref]

```
pointer operator->() const;
```

1 *Returns:* `current`.

24.206.0.3.6 `move_iterator::operator++` [move.iter.op.incr]

```
move_iterator& operator++();
```

1 *Effects:* `++current`.

2 *Returns:* `*this`.

```
move_iterator operator++(int);
```

3 *Effects:*

```
move_iterator tmp = *this;
++current;
return tmp;
```

24.206.0.3.7 `move_iterator::operator--` [move.iter.op.decr]

```
move_iterator& operator--();
```

1 *Effects:* `--current`.

2 *Returns:* `*this`.

```
move_iterator operator--(int);
```

3 *Effects:*

```
move_iterator tmp = *this;
--current;
return tmp;
```

24.206.0.3.8 `move_iterator::operator+` [move.iter.op.+]

```
move_iterator operator+(difference_type n) const;
```

1 *Returns:* `move_iterator(current + n)`.

24.206.0.3.9 `move_iterator::operator+=` [move.iter.op.+=]

```
move_iterator& operator+=(difference_type n);
```

1 *Effects:* `current += n`.

2 *Returns:* `*this`.

24.206.0.3.10 `move_iterator::operator-` [move.iter.op.-]

```
move_iterator operator-(difference_type n) const;
```

1 *Returns:* `move_iterator(current - n)`.

24.206.0.3.11 `move_iterator::operator-=` [move.iter.op.-=]

```
move_iterator& operator-=(difference_type n);
```

1 *Effects:* `current -= n`.

2 *Returns:* `*this`.

24.206.0.3.12 `move_iterator::operator[]` [move.iter.op.index]

```
unspecified  operator[](difference_type n) const;
```

1 *Returns:* `std::move(current[n])`.

24.206.0.3.13 `move_iterator` comparisons [move.iter.op.comp]

```
template <class Iterator1, class Iterator2>
bool operator==(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

1 *Returns:* `x.base() == y.base()`.

```
template <class Iterator1, class Iterator2>
bool operator!=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

2 *Returns:* `!(x == y)`.

```
template <class Iterator1, class Iterator2>
bool operator<(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

3 *Returns:* `x.base() < y.base()`.

```
template <class Iterator1, class Iterator2>
bool operator<=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

4 *Returns:* `!(y < x)`.

```
template <class Iterator1, class Iterator2>
bool operator>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

5 *Returns:* `y < x`.

```
template <class Iterator1, class Iterator2>
bool operator>=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

6 *Returns:* `!(x < y)`.

24.206.0.3.14 `move_iterator` non-member functions [move.iter.nonmember]

```
template <class Iterator1, class Iterator2>
    auto operator-(
    const move_iterator<Iterator1>& x,
    const move_iterator<Iterator2>& y) -> decltype(x.base() - y.base());
```

1 *Returns:* `x.base() - y.base()`.

```
template <class Iterator>
  move_iterator<Iterator> operator+(
    typename move_iterator<Iterator>::difference_type n, const move_iterator<Iterator>& x);
```

2 *Returns:* `x + n`.

```
template <class Iterator>
move_iterator<Iterator> make_move_iterator(Iterator i);
```

3 *Returns:* `move_iterator<Iterator>(i)`.

24.207 Stream iterators [stream.iterators]

1 To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

[*Example:*

```
partial_sum(istream_iterator<double, char>(cin),
  istream_iterator<double, char>(),
  ostream_iterator<double, char>(cout, "\n"));
```

reads a file containing floating point numbers from `cin`, and prints the partial sums onto `cout`. — *end example*]

24.207.1 Class template `istream_iterator` [istream.iterator]

1

The class template `istream_iterator` is an input iterator (24.100.1) that reads (using `operator>>`) successive elements from the input stream for which it was constructed. After it is constructed, and every time `++` is used, the iterator reads and stores a value of `T`. If the iterator fails to read and store a value of `T` (`fail()` on the stream returns `true`), the iterator becomes equal to the *end-of-stream* iterator value. The constructor with no arguments `istream_iterator()` always constructs an end-of-stream input iterator object, which is the only legitimate iterator to be used for the end condition. The result of `operator*` on an end-of-stream iterator is not defined. For any other iterator value a `const T&` is returned. The result of `operator->` on an end-of-stream iterator is not defined. For any other iterator value a `const T*` is returned. The behavior of a program that applies `operator++()` to an end-of-stream iterator is undefined. It is impossible to store things into istream iterators.

1

Two end-of-stream iterators are always equal. An end-of-stream iterator is not equal to a non-end-of-stream iterator. Two non-end-of-stream iterators are equal when they are constructed from the same stream.

```
namespace std {
  template <class T, class charT = char, class traits = char_traits<charT>,
      class Distance = ptrdiff_t>
  class istream_iterator:
    public iterator<input_iterator_tag, T, Distance, const T*, const T&> {
  public:
    typedef charT char_type;
    typedef traits traits_type;
    typedef basic_istream<charT,traits> istream_type;
    see below istream_iterator();
    istream_iterator(istream_type& s);
    istream_iterator(const istream_iterator& x) = default;
   ~istream_iterator() = default;

    const T& operator*() const;
    const T* operator->() const;
    istream_iterator<T,charT,traits,Distance>& operator++();
    istream_iterator<T,charT,traits,Distance>  operator++(int);
```

```
  private:
    basic_istream<charT,traits>* in_stream; // exposition only
    T value;                                // exposition only
  };

  template <class T, class charT, class traits, class Distance>
    bool operator==(const istream_iterator<T,charT,traits,Distance>& x,
            const istream_iterator<T,charT,traits,Distance>& y);
  template <class T, class charT, class traits, class Distance>
    bool operator!=(const istream_iterator<T,charT,traits,Distance>& x,
            const istream_iterator<T,charT,traits,Distance>& y);
}
```

24.215.0.1 `istream_iterator` constructors and destructor [istream.iterator.cons]

see below `istream_iterator();`

1 *Effects:* Constructs the end-of-stream iterator. If `T` is a literal type, then this constructor shall be a `constexpr` constructor.

2 *Postcondition:* `in_stream == 0`.

`istream_iterator(istream_type& s);`

3 *Effects:* Initializes *in_stream* with `&s`. *value* may be initialized during construction or the first time it is referenced.

1 *Postcondition:* `in_stream == &s`.

`istream_iterator(const istream_iterator& x) = default;`

2 *Effects:* Constructs a copy of `x`. If `T` is a literal type, then this constructor shall be a trivial copy constructor.

3 *Postcondition:* `in_stream == x.in_stream`.

`~istream_iterator() = default;`

4 *Effects:* The iterator is destroyed. If `T` is a literal type, then this destructor shall be a trivial destructor.

24.218.0.1 `istream_iterator` operations [istream.iterator.ops]

`const T& operator*() const;`

1 *Returns: value.*

`const T* operator->() const;`

2 *Returns:* `&(operator*())`.

`istream_iterator<T,charT,traits,Distance>& operator++();`

3 *Requires:* `in_stream != 0`.

4 *Effects:* `*in_stream >>value`.

5 *Returns:* `*this`.

`istream_iterator<T,charT,traits,Distance> operator++(int);`

6 *Requires:* `in_stream != 0`.

7 *Effects:*

```
istream_iterator<T,charT,traits,Distance> tmp = *this;
*in_stream >> value;
return (tmp);
```

```
template <class T, class charT, class traits, class Distance>
  bool operator==(const istream_iterator<T,charT,traits,Distance> &x,
                  const istream_iterator<T,charT,traits,Distance> &y);
```

8 *Returns:* `x.in_stream == y.in_stream`.

```
template <class T, class charT, class traits, class Distance>
  bool operator!=(const istream_iterator<T,charT,traits,Distance> &x,
                  const istream_iterator<T,charT,traits,Distance> &y);
```

9 *Returns:* `!(x == y)`

24.218.1 Class template `ostream_iterator` [ostream.iterator]

1

`ostream_iterator` writes (using `operator<<`) successive elements onto the output stream from which it was constructed. If it was constructed with `charT*` as a constructor argument, this string, called a *delimiter string*, is written to the stream after every `T` is written. It is not possible to get a value out of the output iterator. Its only use is as an output iterator in situations like

```
while (first != last)
  *result++ = *first++;
```

1 `ostream_iterator` is defined as:

```
namespace std {
  template <class T, class charT = char, class traits = char_traits<charT> >
  class ostream_iterator:
    public iterator<output_iterator_tag, void, void, void, void> {
  public:
    typedef charT char_type;
    typedef traits traits_type;
    typedef basic_ostream<charT,traits> ostream_type;
    ostream_iterator(ostream_type& s);
    ostream_iterator(ostream_type& s, const charT* delimiter);
    ostream_iterator(const ostream_iterator<T,charT,traits>& x);
   ~ostream_iterator();
    ostream_iterator<T,charT,traits>& operator=(const T& value);

    ostream_iterator<T,charT,traits>& operator*();
    ostream_iterator<T,charT,traits>& operator++();
    ostream_iterator<T,charT,traits>& operator++(int);
  private:
    basic_ostream<charT,traits>* out_stream;  // exposition only
    const charT* delim;                       // exposition only
  };
}
```

24.219.0.1 `ostream_iterator` constructors and destructor [ostream.iterator.cons.des]

`ostream_iterator(ostream_type& s);`

1 *Effects:* Initializes *out_stream* with `&s` and *delim* with null.

`ostream_iterator(ostream_type& s, const charT* delimiter);`

2 *Effects:* Initializes *out_stream* with `&s` and *delim* with `delimiter`.

`ostream_iterator(const ostream_iterator& x);`

3 *Effects:* Constructs a copy of `x`.

`~ostream_iterator();`

4 *Effects:* The iterator is destroyed.

24.219.0.2 `ostream_iterator` operations [ostream.iterator.ops]

`ostream_iterator& operator=(const T& value);`

1 *Effects:*

```
*out_stream << value;
if (delim != 0)
  *out_stream << delim;
return *this;
```

`ostream_iterator& operator*();`

2 *Returns:* `*this`.

```
ostream_iterator& operator++();
ostream_iterator& operator++(int);
```

3 *Returns:* `*this`.

24.219.1 Class template `istreambuf_iterator` [istreambuf.iterator]

1 The class template `istreambuf_iterator` defines an input iterator (24.100.1) that reads successive *characters* from the streambuf for which it was constructed. `operator*` provides access to the current input character, if any. [*Note:* `operator->` may return a proxy. — *end note*] Each time `operator++` is evaluated, the iterator advances to the next input character. If the end of stream is reached (`streambuf_type::sgetc()` returns `traits::eof()`), the iterator becomes equal to the *end-of-stream* iterator value. The default constructor `istreambuf_iterator()` and the constructor `istreambuf_iterator(0)` both construct an end-of-stream iterator object suitable for use as an end-of-range. All specializations of `istreambuf_iterator` shall have a trivial copy constructor, a `constexpr` default constructor, and a trivial destructor.

2 The result of `operator*()` on an end-of-stream iterator is undefined. For any other iterator value a `char_type` value is returned. It is impossible to assign a character via an input iterator.

```
namespace std {
  template<class charT, class traits = char_traits<charT> >
  class istreambuf_iterator
     : public iterator<input_iterator_tag, charT,
                       typename traits::off_type, unspecified , charT> {
  public:
    typedef charT                          char_type;
    typedef traits                         traits_type;
```

```
    typedef typename traits::int_type     int_type;
    typedef basic_streambuf<charT,traits> streambuf_type;
    typedef basic_istream<charT,traits>   istream_type;

    class proxy;                          // exposition only

    constexpr istreambuf_iterator() noexcept;
    istreambuf_iterator(const istreambuf_iterator&) noexcept = default;
    ~istreambuf_iterator() = default;
    istreambuf_iterator(istream_type& s) noexcept;
    istreambuf_iterator(streambuf_type* s) noexcept;
    istreambuf_iterator(const proxy& p) noexcept;
    charT operator*() const;
    pointer operator->() const;
    istreambuf_iterator<charT,traits>& operator++();
    proxy operator++(int);
    bool equal(const istreambuf_iterator& b) const;
  private:
    streambuf_type* sbuf_;                // exposition only
  };

  template <class charT, class traits>
    bool operator==(const istreambuf_iterator<charT,traits>& a,
            const istreambuf_iterator<charT,traits>& b);
  template <class charT, class traits>
    bool operator!=(const istreambuf_iterator<charT,traits>& a,
            const istreambuf_iterator<charT,traits>& b);
}
```

24.219.1.1 Class template `istreambuf_iterator::proxy` [istreambuf.iterator::proxy]

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
  class istreambuf_iterator<charT, traits>::proxy { // exposition only
    charT keep_;
    basic_streambuf<charT,traits>* sbuf_;
    proxy(charT c, basic_streambuf<charT,traits>* sbuf)
      : keep_(c), sbuf_(sbuf) { }
  public:
    charT operator*() { return keep_; }
  };
}
```

1 Class `istreambuf_iterator<charT,traits>::proxy` is for exposition only. An implementation is permitted to provide equivalent functionality without providing a class with this name. Class `istreambuf_iterator<charT, traits>::proxy` provides a temporary placeholder as the return value of the post-increment operator (`operator++`). It keeps the character pointed to by the previous value of the iterator for some possible future access to get the character.

24.219.1.2 `istreambuf_iterator` constructors [istreambuf.iterator.cons]

```
constexpr istreambuf_iterator() noexcept;
```

1 *Effects:* Constructs the end-of-stream iterator.

```
istreambuf_iterator(basic_istream<charT,traits>& s) noexcept;
istreambuf_iterator(basic_streambuf<charT,traits>* s) noexcept;
```

2 *Effects:* Constructs an `istreambuf_iterator<>` that uses the `basic_streambuf<>` object `*(s.rdbuf())`, or `*s`, respectively. Constructs an end-of-stream iterator if `s.rdbuf()` is null.

```
istreambuf_iterator(const proxy& p) noexcept;
```

3 *Effects:* Constructs a `istreambuf_iterator<>` that uses the `basic_streambuf<>` object pointed to by the `proxy` object's constructor argument `p`.

24.219.1.3 `istreambuf_iterator::operator*` [istreambuf.iterator::op*]

```
charT operator*() const
```

1 *Returns:* The character obtained via the `streambuf` member `sbuf_->sgetc()`.

24.219.1.4 `istreambuf_iterator::operator++` [istreambuf.iterator::op++]

```
istreambuf_iterator<charT,traits>&
    istreambuf_iterator<charT,traits>::operator++();
```

1 *Effects:* `sbuf_->sbumpc()`.

2 *Returns:* `*this`.

```
proxy istreambuf_iterator<charT,traits>::operator++(int);
```

3 *Returns:* `proxy(sbuf_->sbumpc(), sbuf_)`.

24.219.1.5 `istreambuf_iterator::equal` [istreambuf.iterator::equal]

```
bool equal(const istreambuf_iterator<charT,traits>& b) const;
```

1

Returns: `true` if and only if both iterators are at end-of-stream, or neither is at end-of-stream, regardless of what `streambuf` object they use.

24.220.0.1 `operator==` [istreambuf.iterator::op==]

```
template <class charT, class traits>
  bool operator==(const istreambuf_iterator<charT,traits>& a,
                  const istreambuf_iterator<charT,traits>& b);
```

1 *Returns:* `a.equal(b)`.

24.220.0.2 `operator!=` [istreambuf.iterator::op!=]

```
template <class charT, class traits>
  bool operator!=(const istreambuf_iterator<charT,traits>& a,
                  const istreambuf_iterator<charT,traits>& b);
```

1 *Returns:* `!a.equal(b)`.

24.220.1 Class template `ostreambuf_iterator` [ostreambuf.iterator]

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
  class ostreambuf_iterator :
    public iterator<output_iterator_tag, void, void, void, void> {
  public:
    typedef charT                        char_type;
    typedef traits                       traits_type;
    typedef basic_streambuf<charT,traits> streambuf_type;
```

```
    typedef basic_ostream<charT,traits>   ostream_type;

  public:
    ostreambuf_iterator(ostream_type& s) noexcept;
    ostreambuf_iterator(streambuf_type* s) noexcept;
    ostreambuf_iterator& operator=(charT c);

    ostreambuf_iterator& operator*();
    ostreambuf_iterator& operator++();
    ostreambuf_iterator& operator++(int);
    bool failed() const noexcept;

  private:
    streambuf_type* sbuf_;                // exposition only
  };
}
```

1 The class template `ostreambuf_iterator` writes successive *characters* onto the output stream from which it was constructed. It is not possible to get a character value out of the output iterator.

24.220.1.1 `ostreambuf_iterator` constructors [ostreambuf.iter.cons]

`ostreambuf_iterator(ostream_type& s) noexcept;`

1 *Requires:* `s.rdbuf()` shall not be a null pointer.

2 *Effects:* Initializes `sbuf_` with `s.rdbuf()`.

`ostreambuf_iterator(streambuf_type* s) noexcept;`

3 *Requires:* `s` shall not be a null pointer.

4 *Effects:* Initializes `sbuf_` with `s`.

24.220.1.2 `ostreambuf_iterator` operations [ostreambuf.iter.ops]

```
ostreambuf_iterator<charT,traits>&
  operator=(charT c);
```

1 *Effects:* If `failed()` yields `false`, calls `sbuf_->sputc(c)`; otherwise has no effect.

2 *Returns:* `*this`.

`ostreambuf_iterator<charT,traits>& operator*();`

3 *Returns:* `*this`.

```
ostreambuf_iterator<charT,traits>& operator++();
ostreambuf_iterator<charT,traits>& operator++(int);
```

4 *Returns:* `*this`.

`bool failed() const noexcept;`

5 *Returns:* `true` if in any prior use of member `operator=`, the call to `sbuf_->sputc()` returned `traits::eof()`; or `false` otherwise.

24.221 range access [iterator.range]

1

In addition to being available via inclusion of the <iterator> header, the function templates in 24.221 are available when any of the following headers are included: <array>, <deque>, <forward_list>, <list>, <map>, <regex>, <set>, <string>, <unordered_map>, <unordered_set>, and <vector>.

```
template <class C> auto begin(C& c) -> decltype(c.begin());
template <class C> auto begin(const C& c) -> decltype(c.begin());
```

1 *Returns:* `c.begin()`.

```
template <class C> auto end(C& c) -> decltype(c.end());
template <class C> auto end(const C& c) -> decltype(c.end());
```

2 *Returns:* `c.end()`.

```
template <class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept;
```

3 *Returns:* `array`.

```
template <class T, size_t N> constexpr T* end(T (&array)[N]) noexcept;
```

4 *Returns:* `array + N`.

```
template <class C> constexpr auto cbegin(const C& c) noexcept(noexcept(std::begin(c)))
  -> decltype(std::begin(c));
```

5 *Returns:* `std::begin(c)`.

```
template <class C> constexpr auto cend(const C& c) noexcept(noexcept(std::end(c)))
  -> decltype(std::end(c));
```

6 *Returns:* `std::end(c)`.

```
template <class C> auto rbegin(C& c) -> decltype(c.rbegin());
template <class C> auto rbegin(const C& c) -> decltype(c.rbegin());
```

7 *Returns:* `c.rbegin()`.

```
template <class C> auto rend(C& c) -> decltype(c.rend());
template <class C> auto rend(const C& c) -> decltype(c.rend());
```

8 *Returns:* `c.rend()`.

```
template <class T, size_t N> reverse_iterator<T*> rbegin(T (&array)[N]);
```

9 *Returns:* `reverse_iterator<T*>(array + N)`.

```
template <class T, size_t N> reverse_iterator<T*> rend(T (&array)[N]);
```

10 *Returns:* `reverse_iterator<T*>(array)`.

```
template <class E> reverse_iterator<const E*> rbegin(initializer_list<E> il);
```

11 *Returns:* `reverse_iterator<const E*>(il.end())`.

```
template <class E> reverse_iterator<const E*> rend(initializer_list<E> il);
```

12 *Returns:* `reverse_iterator<const E*>(il.begin())`.

```
template <class C> auto crbegin(const C& c) -> decltype(std::rbegin(c));
```

1 *Returns:* `std::rbegin(c)`.

```
template <class C> auto crend(const C& c) -> decltype(std::rend(c));
```

2 *Returns:* `std::rend(c)`.

25 Algorithms library [algorithms]

25.1 General [algorithms.general]

1 This Clause describes components that C++ programs may use to perform algorithmic operations on containers (Clause 23) and other sequences.

2 The following subclauses describe components for non-modifying sequence operation, modifying sequence operations, sorting and related operations, and algorithms from the ISO C library, as summarized in Table 112.

Table 112 — Algorithms library summary

	Subclause	Header(s)
25.23	Non-modifying sequence operations	
25.54	Mutating sequence operations	`<algorithm>`
25.98	Sorting and related operations	
25.205	C library algorithms	`<cstdlib>`

Header `<algorithm>` synopsis

```
#include <initializer_list>

namespace std {

  // 25.23, non-modifying sequence operations:
  template <class InputIterator, class Predicate>
    bool all_of(InputIterator first, InputIterator last, Predicate pred);
  template <class InputIterator, class Predicate>
    bool any_of(InputIterator first, InputIterator last, Predicate pred);
  template <class InputIterator, class Predicate>
    bool none_of(InputIterator first, InputIterator last, Predicate pred);

  template<class InputIterator, class Function>
    Function for_each(InputIterator first, InputIterator last, Function f);
  template<class InputIterator, class T>
    InputIterator find(InputIterator first, InputIterator last,
                       const T& value);
  template<class InputIterator, class Predicate>
    InputIterator find_if(InputIterator first, InputIterator last,
                          Predicate pred);
  template<class InputIterator, class Predicate>
    InputIterator find_if_not(InputIterator first, InputIterator last,
                              Predicate pred);

}
```

3

All of the algorithms are separated from the particular implementations of data structures and are parameterized by iterator types. Because of this, they can work with program-defined data structures, as long as these data structures have iterator types satisfying the assumptions on the algorithms.

1 For purposes of determining the existence of data races, algorithms shall not modify objects referenced through an iterator argument unless the specification requires such modification.

2

Throughout this Clause, the names of template parameters are used to express type requirements.

— If an algorithm's template parameter is named `InputIterator`, `InputIterator1`, or `InputIterator2`, the template argument shall satisfy the requirements of an input iterator (24.100.1).

— If an algorithm's template parameter is named `OutputIterator`, `OutputIterator1`, or `OutputIterator2`, the template argument shall satisfy the requirements of an output iterator (24.116.1).

— If an algorithm's template parameter is named `ForwardIterator`, `ForwardIterator1`, or `ForwardIterator2`, the template argument shall satisfy the requirements of a forward iterator (24.122.1).

— If an algorithm's template parameter is named `BidirectionalIterator`, `BidirectionalIterator1`, or `BidirectionalIterator2`, the template argument shall satisfy the requirements of a bidirectional iterator (24.165.1).

— If an algorithm's template parameter is named `RandomAccessIterator`, `RandomAccessIterator1`, or `RandomAccessIterator2`, the template argument shall satisfy the requirements of a random-access iterator (24.167.1).

1 If an algorithm's **Effects** section says that a value pointed to by any iterator passed as an argument is modified, then that algorithm has an additional type requirement: The type of that argument shall satisfy the requirements of a mutable iterator (24.2). [*Note:* This requirement does not affect arguments that are named `OutputIterator`, `OutputIterator1`, or `OutputIterator2`, because output iterators must always be mutable. — *end note*]

2

Both in-place and copying versions are provided for certain algorithms.[268] When such a version is provided

268) The decision whether to include a copying version was usually based on complexity considerations. When the cost of doing the operation dominates the cost of copy, the copying version is not included. For example, `sort_copy` is not included because the cost of sorting is much more significant, and users might as well do `copy` followed by `sort`.

for *algorithm* it is called *algorithm*`_copy`. Algorithms that take predicates end with the suffix `_if` (which follows the suffix `_copy`).

1

The `Predicate` parameter is used whenever an algorithm expects a function object (20.283) that, when applied to the result of dereferencing the corresponding iterator, returns a value testable as `true`. In other words, if an algorithm takes `Predicate pred` as its argument and `first` as its iterator argument, it should work correctly in the construct `pred(*first)` contextually converted to `bool` (Clause 4). The function object `pred` shall not apply any non-constant function through the dereferenced iterator.

1

The `BinaryPredicate` parameter is used whenever an algorithm expects a function object that when applied to the result of dereferencing two corresponding iterators or to dereferencing an iterator and type `T` when `T` is part of the signature returns a value testable as `true`. In other words, if an algorithm takes `BinaryPredicate binary_pred` as its argument and `first1` and `first2` as its iterator arguments, it should work correctly in the construct `binary_pred(*first1, *first2)` contextually converted to `bool` (Clause 4). `BinaryPredicate` always takes the first iterator's `value_type` as its first argument, that is, in those cases when `T value` is part of the signature, it should work correctly in the construct `binary_pred(*first1, value)` contextually converted to `bool` (Clause 4). `binary_pred` shall not apply any non-constant function through the dereferenced iterators.

1

[*Note:* Unless otherwise specified, algorithms that take function objects as arguments are permitted to copy those function objects freely. Programmers for whom object identity is important should consider using a wrapper class that points to a noncopied implementation object such as `reference_wrapper<T>` (20.339.1), or some equivalent solution. — *end note*]

1 When the description of an algorithm gives an expression such as `*first == value` for a condition, the expression shall evaluate to either true or false in boolean contexts.

2

In the description of the algorithms operators `+` and `-` are used for some of the iterator categories for which they do not have to be defined. In these cases the semantics of `a+n` is the same as that of

```
X tmp = a;
advance(tmp, n);
return tmp;
```

and that of `b-a` is the same as of

```
return distance(a, b);
```

25.23 Non-modifying sequence operations [alg.nonmodifying]

25.23.1 All of [alg.all_of]

```
template <class InputIterator, class Predicate>
  bool all_of(InputIterator first, InputIterator last, Predicate pred);
```

1

Returns: `true` if `[first,last)` is empty or if `pred(*i)` is `true` for every iterator `i` in the range `[first,last)`, and `false` otherwise.

1 *Complexity:* At most `last - first` applications of the predicate.

25.24.1 Any of [alg.any_of]

```
template <class InputIterator, class Predicate>
  bool any_of(InputIterator first, InputIterator last, Predicate pred);
```

1 *Returns:* `false` if `[first,last)` is empty or if there is no iterator `i` in the range `[first,last)` such that `pred(*i)` is `true`, and `true` otherwise.

2 *Complexity:* At most `last - first` applications of the predicate.

25.24.2 None of [alg.none_of]

```
template <class InputIterator, class Predicate>
  bool none_of(InputIterator first, InputIterator last, Predicate pred);
```

1 *Returns:* `true` if `[first,last)` is empty or if `pred(*i)` is `false` for every iterator `i` in the range `[first,last)`, and `false` otherwise.

2 *Complexity:* At most `last - first` applications of the predicate.

25.24.3 For each [alg.foreach]

```
template<class InputIterator, class Function>
  Function for_each(InputIterator first, InputIterator last, Function f);
```

1

Requires: `Function` shall meet the requirements of `MoveConstructible` (Table 20). [*Note:* `Function` need not meet the requirements of `CopyConstructible` (Table 21). — *end note*]

1

Effects: Applies `f` to the result of dereferencing every iterator in the range `[first,last)`, starting from `first` and proceeding to `last - 1`. [*Note:* If the type of `first` satisfies the requirements of a mutable iterator, `f` may apply nonconstant functions through the dereferenced iterator. — *end note*]

1 *Returns:* `std::move(f)`.

2

Complexity: Applies `f` exactly `last - first` times.

1

Remarks: If `f` returns a result, the result is ignored.

25.36.1 Find [alg.find]

```
template<class InputIterator, class T>
  InputIterator find(InputIterator first, InputIterator last,
                     const T& value);

template<class InputIterator, class Predicate>
  InputIterator find_if(InputIterator first, InputIterator last,
                        Predicate pred);
template<class InputIterator, class Predicate>
  InputIterator find_if_not(InputIterator first, InputIterator last,
                            Predicate pred);
```

1

Returns: The first iterator `i` in the range `[first,last)` for which the following corresponding conditions hold: `*i == value`, `pred(*i) != false`, `pred(*i) == false`. Returns `last` if no such iterator is found.

1

Complexity: At most `last - first` applications of the corresponding predicate.

25.42.1 Find end [alg.find.end]

```
template<class ForwardIterator1, class ForwardIterator2>
  ForwardIterator1
    find_end(ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
  ForwardIterator1
    find_end(ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2, ForwardIterator2 last2,
             BinaryPredicate pred);
```

1

Effects: Finds a subsequence of equal values in a sequence.

1 *Returns:* The last iterator `i` in the range `[first1,last1 - (last2 - first2))` such that for every non-negative integer `n < (last2 - first2)`, the following corresponding conditions hold: `*(i + n) == *(first2 + n), pred(*(i + n), *(first2 + n)) != false`. Returns `last1` if `[first2,last2)` is empty or if no such iterator is found.

2

Complexity: At most `(last2 - first2) * (last1 - first1 - (last2 - first2) + 1)` applications of the corresponding predicate.

25.44.1 Find first [alg.find.first.of]

```
template<class InputIterator, class ForwardIterator>
  InputIterator
    find_first_of(InputIterator first1, InputIterator last1,
                  ForwardIterator first2, ForwardIterator last2);

template<class InputIterator, class ForwardIterator,
         class BinaryPredicate>
  InputIterator
    find_first_of(InputIterator first1, InputIterator last1,
                  ForwardIterator first2, ForwardIterator last2,
                  BinaryPredicate pred);
```

1 *Effects:* Finds an element that matches one of a set of values.

2 *Returns:* The first iterator `i` in the range `[first1,last1)` such that for some iterator `j` in the range `[first2,last2)` the following conditions hold: `*i == *j, pred(*i,*j) != false`. Returns `last1` if `[first2,last2)` is empty or if no such iterator is found.

3 *Complexity:* At most `(last1-first1) * (last2-first2)` applications of the corresponding predicate.

25.44.2 Adjacent find [alg.adjacent.find]

```
template<class ForwardIterator>
  ForwardIterator adjacent_find(ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
  ForwardIterator adjacent_find(ForwardIterator first, ForwardIterator last,
                                BinaryPredicate pred);
```

1 *Returns:* The first iterator `i` such that both `i` and `i + 1` are in the range `[first,last)` for which the following corresponding conditions hold: `*i == *(i + 1), pred(*i, *(i + 1)) != false`. Returns `last` if no such iterator is found.

2 *Complexity:* For a nonempty range, exactly `min((i - first) + 1, (last - first) - 1)` applications of the corresponding predicate, where `i` is `adjacent_find`'s return value.

25.44.3 Count [alg.count]

```
template<class InputIterator, class T>
    typename iterator_traits<InputIterator>::difference_type
       count(InputIterator first, InputIterator last, const T& value);

template<class InputIterator, class Predicate>
    typename iterator_traits<InputIterator>::difference_type
      count_if(InputIterator first, InputIterator last, Predicate pred);
```

1 *Effects:* Returns the number of iterators `i` in the range `[first,last)` for which the following corresponding conditions hold: `*i == value, pred(*i) != false`.

2 *Complexity:* Exactly `last - first` applications of the corresponding predicate.

25.45.1 Mismatch [mismatch]

```
template<class InputIterator1, class InputIterator2>
  pair<InputIterator1, InputIterator2>
      mismatch(InputIterator1 first1, InputIterator1 last1,
               InputIterator2 first2);

template<class InputIterator1, class InputIterator2,
          class BinaryPredicate>
  pair<InputIterator1, InputIterator2>
      mismatch(InputIterator1 first1, InputIterator1 last1,
               InputIterator2 first2, BinaryPredicate pred);

template<class InputIterator1, class InputIterator2>
  pair<InputIterator1, InputIterator2>
    mismatch(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, InputIterator2 last2);

template <class InputIterator1, class InputIterator2,
           class BinaryPredicate>
  pair<InputIterator1, InputIterator2>
    mismatch(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, InputIterator2 last2,
             BinaryPredicate pred);
```

1 *Remarks:* If `last2` was not given in the argument list, it denotes `first2 + (last1 - first1)` below.

1 *Returns:* A pair of iterators `i` and `j` such that `j == first2 + (i - first1)` and `i` is the first iterator in the range `[first1,last1)` for which the following corresponding conditions hold:

(1.1) — `j` is in the range `[first2, last2)`.

(1.2) — `!(*i == *(first2 + (i - first1)))`

(1.3) — `pred(*i, *(first2 + (i - first1))) == false`

Returns the pair `first1 + min(last1 - first1, last2 - first2)` and `first2 + min(last1 - first1, last2 - first2)` if such an iterator `i` is not found.

2 *Complexity:* At most `last1 - first1` applications of the corresponding predicate.

25.46.1 Equal [alg.equal]

```
template<class InputIterator1, class InputIterator2>
  bool equal(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2);

template<class InputIterator1, class InputIterator2,
          class BinaryPredicate>
  bool equal(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, BinaryPredicate pred);

template<class InputIterator1, class InputIterator2>
  bool equal(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, InputIterator2 last2);

template<class InputIterator1, class InputIterator2,
           class BinaryPredicate>
  bool equal(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, InputIterator2 last2,
             BinaryPredicate pred);
```

1 *Remarks:* If `last2` was not given in the argument list, it denotes `first2 + (last1 - first1)` below.

2

Returns: If `last1 - first1 != last2 - first2`, return `false`. Otherwise return `true` if for every iterator `i` in the range `[first1,last1)` the following corresponding conditions hold: `*i == *(first2 + (i - first1))`, `pred(*i, *(first2 + (i - first1))) != false`. Otherwise, returns `false`.

1 *Complexity:* No applications of the corresponding predicate if `InputIterator1` and `InputIterator2` meet the requirements of random access iterators and `last1 - first1 != last2 - first2`. Otherwise, at most `min(last1 - first1, last2 - first2)` applications of the corresponding predicate.

25.49.1 Is permutation [alg.is_permutation]

```
template<class ForwardIterator1, class ForwardIterator2>
  bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                      ForwardIterator2 first2);
template<class ForwardIterator1, class ForwardIterator2,
                 class BinaryPredicate>
  bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                      ForwardIterator2 first2, BinaryPredicate pred);
template<class ForwardIterator1, class ForwardIterator2>
  bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                      ForwardIterator2 first2, ForwardIterator2 last2);
template<class ForwardIterator1, class ForwardIterator2,
                 class BinaryPredicate>
  bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                      ForwardIterator2 first2, ForwardIterator2 last2,
                      BinaryPredicate pred);
```

1

Requires: `ForwardIterator1` and `ForwardIterator2` shall have the same value type. The comparison function shall be an equivalence relation.

1 *Remarks:* If `last2` was not given in the argument list, it denotes `first2 + (last1 - first1)` below.

2 *Returns:* If `last1 - first1 != last2 - first2`, return `false`. Otherwise return `true` if there exists a permutation of the elements in the range `[first2,first2 + (last1 - first1))`, beginning with `ForwardIterator2 begin`, such that `equal(first1, last1, begin)` returns `true` or `equal(first1, last1, begin, pred)` returns `true`; otherwise, returns `false`.

3 *Complexity:* No applications of the corresponding predicate if `ForwardIterator1` and `ForwardIterator2` meet the requirements of random access iterators and `last1 - first1 != last2 - first2`. Otherwise, exactly `distance(first1, last1)` applications of the corresponding predicate if `equal(first1, last1, first2, last2)` would return `true` if `pred` was not given in the argument list or `equal(first1, last1, first2, last2, pred)` would return `true` if pred was given in the argument list; otherwise, at worst $\mathcal{O}(N^2)$, where N has the value `distance(first1, last1)`.

25.50.1 Search [alg.search]

```
template<class ForwardIterator1, class ForwardIterator2>
  ForwardIterator1
    search(ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
  ForwardIterator1
    search(ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, ForwardIterator2 last2,
           BinaryPredicate pred);
```

1 *Effects:* Finds a subsequence of equal values in a sequence.

2 *Returns:* The first iterator `i` in the range `[first1,last1 - (last2-first2))` such that for every non-negative integer `n` less than `last2 - first2` the following corresponding conditions hold: `*(i + n) == *(first2 + n), pred(*(i + n), *(first2 + n)) != false`. Returns `first1` if `[first2, last2)` is empty, otherwise returns `last1` if no such iterator is found.

1 *Complexity:* At most `(last1 - first1) * (last2 - first2)` applications of the corresponding predicate.

```
template<class ForwardIterator, class Size, class T>
  ForwardIterator
    search_n(ForwardIterator first, ForwardIterator last, Size count,
             const T& value);

template<class ForwardIterator, class Size, class T,
         class BinaryPredicate>
  ForwardIterator
    search_n(ForwardIterator first, ForwardIterator last, Size count,
             const T& value, BinaryPredicate pred);
```

2 *Requires:* The type `Size` shall be convertible to integral type (4.397, 12.659).

1 *Effects:* Finds a subsequence of equal values in a sequence.

2

Returns: The first iterator `i` in the range `[first,last-count)` such that for every non-negative integer `n` less than `count` the following corresponding conditions hold: `*(i + n) == value, pred(*(i + n),value) != false`. Returns `last` if no such iterator is found.

1 *Complexity:* At most `last - first` applications of the corresponding predicate.

25.54 Mutating sequence operations [alg.modifying.operations]

25.54.1 Copy [alg.copy]

```
template<class InputIterator, class OutputIterator>
  OutputIterator copy(InputIterator first, InputIterator last,
                      OutputIterator result);
```

1

Effects: Copies elements in the range `[first,last)` into the range `[result,result + (last - first))` starting from `first` and proceeding to `last`. For each non-negative integer `n < (last - first)`, performs `*(result + n) = *(first + n)`.

1 *Returns:* `result + (last - first)`.

2 *Requires:* `result` shall not be in the range `[first,last)`.

3

Complexity: Exactly `last - first` assignments.

```
template<class InputIterator, class Size, class OutputIterator>
  OutputIterator copy_n(InputIterator first, Size n,
                        OutputIterator result);
```

1 *Effects:* For each non-negative integer $i < n$, performs `*(result + i) = *(first + i)`.

2 *Returns:* `result + n`.

3 *Complexity:* Exactly `n` assignments.

```
template<class InputIterator, class OutputIterator, class Predicate>
  OutputIterator copy_if(InputIterator first, InputIterator last,
                         OutputIterator result, Predicate pred);
```

4 *Requires:* The ranges `[first,last)` and `[result,result + (last - first))` shall not overlap.

5 *Effects:* Copies all of the elements referred to by the iterator `i` in the range `[first,last)` for which `pred(*i)` is `true`.

6 *Returns:* The end of the resulting range.

7 *Complexity:* Exactly `last - first` applications of the corresponding predicate.

8 *Remarks:* Stable (17.602.0.1).

```
template<class BidirectionalIterator1, class BidirectionalIterator2>
  BidirectionalIterator2
    copy_backward(BidirectionalIterator1 first,
                  BidirectionalIterator1 last,
                  BidirectionalIterator2 result);
```

9 *Effects:* Copies elements in the range `[first,last)` into the range `[result - (last-first),result)` starting from `last - 1` and proceeding to `first`.[269] For each positive integer `n <= (last - first)`, performs `*(result - n) = *(last - n)`.

269) `copy_backward` should be used instead of copy when `last` is in the range `[result - (last - first),result)`.

10 *Requires:* `result` shall not be in the range `(first,last]`.

11 *Returns:* `result - (last - first)`.

12 *Complexity:* Exactly `last - first` assignments.

25.65.1 Move [alg.move]

```
template<class InputIterator, class OutputIterator>
  OutputIterator move(InputIterator first, InputIterator last,
                      OutputIterator result);
```

1 *Effects:* Moves elements in the range `[first,last)` into the range `[result,result + (last - first))` starting from first and proceeding to last. For each non-negative integer `n < (last-first)`, performs `*(result + n) = std::move(*(first + n))`.

2 *Returns:* `result + (last - first)`.

3 *Requires:* `result` shall not be in the range `[first,last)`.

4 *Complexity:* Exactly `last - first` move assignments.

```
template<class BidirectionalIterator1, class BidirectionalIterator2>
  BidirectionalIterator2
    move_backward(BidirectionalIterator1 first,
                  BidirectionalIterator1 last,
                  BidirectionalIterator2 result);
```

5 *Effects:* Moves elements in the range `[first,last)` into the range `[result - (last-first),result )` starting from `last - 1` and proceeding to first.[270] For each positive integer `n <= (last - first)`, performs `*(result - n) = std::move(*(last - n))`.

6 *Requires:* `result` shall not be in the range `(first,last]`.

7 *Returns:* `result - (last - first)`.

8 *Complexity:* Exactly `last - first` assignments.

25.65.2 swap [alg.swap]

```
template<class ForwardIterator1, class ForwardIterator2>
  ForwardIterator2
    swap_ranges(ForwardIterator1 first1, ForwardIterator1 last1,
                ForwardIterator2 first2);
```

1 *Effects:* For each non-negative integer `n < (last1 - first1)` performs: `swap(*(first1 + n), *(first2 + n))`.

2 *Requires:* The two ranges `[first1,last1)` and `[first2,first2 + (last1 - first1))` shall not overlap. `*(first1 + n)` shall be swappable with (17.143.0.1) `*(first2 + n)`.

3 *Returns:* `first2 + (last1 - first1)`.

4 *Complexity:* Exactly `last1 - first1` swaps.

```
template<class ForwardIterator1, class ForwardIterator2>
  void iter_swap(ForwardIterator1 a, ForwardIterator2 b);
```

5 *Effects:* `swap(*a, *b)`.

6 *Requires:* `a` and `b` shall be dereferenceable. `*a` shall be swappable with (17.143.0.1) `*b`.

270) `move_backward` should be used instead of move when last is in the range `[result - (last - first),result)`.

25.65.3 Transform [alg.transform]

```
template<class InputIterator, class OutputIterator,
         class UnaryOperation>
  OutputIterator
    transform(InputIterator first, InputIterator last,
              OutputIterator result, UnaryOperation op);

template<class InputIterator1, class InputIterator2,
         class OutputIterator, class BinaryOperation>
  OutputIterator
    transform(InputIterator1 first1, InputIterator1 last1,
              InputIterator2 first2, OutputIterator result,
              BinaryOperation binary_op);
```

1

Effects: Assigns through every iterator `i` in the range `[result,result + (last1 - first1))` a new corresponding value equal to `op(*(first1 + (i - result))` or `binary_op(*(first1 + (i - result)), *(first2 + (i - result)))`.

1

Requires: `op` and `binary_op` shall not invalidate iterators or subranges, or modify elements in the ranges `[first1,last1]`, `[first2,first2 + (last1 - first1)]`, and `[result,result + (last1 - first1)]`.[271]

1 *Returns:* `result + (last1 - first1)`.

2

Complexity: Exactly `last1 - first1` applications of `op` or `binary_op`.

1

Remarks: `result` may be equal to `first` in case of unary transform, or to `first1` or `first2` in case of binary transform.

25.73.1 Replace [alg.replace]

```
template<class ForwardIterator, class T>
  void replace(ForwardIterator first, ForwardIterator last,
               const T& old_value, const T& new_value);

template<class ForwardIterator, class Predicate, class T>
  void replace_if(ForwardIterator first, ForwardIterator last,
                  Predicate pred, const T& new_value);
```

1 *Requires:* The expression `*first = new_value` shall be valid.

2 *Effects:* Substitutes elements referred by the iterator `i` in the range `[first,last)` with `new_value`, when the following corresponding conditions hold: `*i == old_value`, `pred(*i) != false`.

3 *Complexity:* Exactly `last - first` applications of the corresponding predicate.

```
template<class InputIterator, class OutputIterator, class T>
  OutputIterator
    replace_copy(InputIterator first, InputIterator last,
                 OutputIterator result,
                 const T& old_value, const T& new_value);
```

271) The use of fully closed ranges is intentional.

```
template<class InputIterator, class OutputIterator, class Predicate, class T>
  OutputIterator
    replace_copy_if(InputIterator first, InputIterator last,
                    OutputIterator result,
                    Predicate pred, const T& new_value);
```

4 *Requires:* The results of the expressions `*first` and `new_value` shall be writable to the `result` output iterator. The ranges `[first,last)` and `[result,result + (last - first))` shall not overlap.

5 *Effects:* Assigns to every iterator `i` in the range `[result,result + (last - first))` either `new_value` or `*(first + (i - result))` depending on whether the following corresponding conditions hold:

```
*(first + (i - result)) == old_value
pred(*(first + (i - result))) != false
```

6 *Returns:* `result + (last - first)`.

7 *Complexity:* Exactly `last - first` applications of the corresponding predicate.

25.73.2 Fill [alg.fill]

```
template<class ForwardIterator, class T>
  void fill(ForwardIterator first, ForwardIterator last, const T& value);

template<class OutputIterator, class Size, class T>
  OutputIterator fill_n(OutputIterator first, Size n, const T& value);
```

1 *Requires:* The expression `value` shall be writable to the output iterator. The type `Size` shall be convertible to an integral type (4.397, 12.659).

2 *Effects:* The first algorithm assigns `value` through all the iterators in the range `[first,last)`. The second algorithm assigns `value` through all the iterators in the range `[first,first + n)` if `n` is positive, otherwise it does nothing.

3 *Returns:* `fill_n` returns `first + n` for non-negative values of `n` and `first` for negative values.

4 *Complexity:* Exactly `last - first`, `n`, or 0 assignments, respectively.

25.73.3 Generate [alg.generate]

```
template<class ForwardIterator, class Generator>
  void generate(ForwardIterator first, ForwardIterator last,
                Generator gen);

template<class OutputIterator, class Size, class Generator>
  OutputIterator generate_n(OutputIterator first, Size n, Generator gen);
```

1

Effects: The first algorithm invokes the function object `gen` and assigns the return value of `gen` through all the iterators in the range `[first,last)`. The second algorithm invokes the function object `gen` and assigns the return value of `gen` through all the iterators in the range `[first,first + n)` if `n` is positive, otherwise it does nothing.

1

Requires: `gen` takes no arguments, `Size` shall be convertible to an integral type (4.397, 12.659).

1

Returns: `generate_n` returns `first + n` for non-negative values of `n` and `first` for negative values.

1

Complexity: Exactly `last - first`, `n`, or 0 invocations of `gen` and assignments, respectively.

25.81.1 Remove [alg.remove]

```
template<class ForwardIterator, class T>
  ForwardIterator remove(ForwardIterator first, ForwardIterator last,
                         const T& value);

template<class ForwardIterator, class Predicate>
  ForwardIterator remove_if(ForwardIterator first, ForwardIterator last,
                            Predicate pred);
```

1

Requires: The type of `*first` shall satisfy the `MoveAssignable` requirements (Table 22).

1

Effects: Eliminates all the elements referred to by iterator `i` in the range `[first,last)` for which the following corresponding conditions hold: `*i == value, pred(*i) != false`.

1 *Returns:* The end of the resulting range.

2 *Remarks:* Stable (17.602.0.1).

3 *Complexity:* Exactly `last - first` applications of the corresponding predicate.

4

Note: each element in the range `[ret,last)`, where `ret` is the returned value, has a valid but unspecified state, because the algorithms can eliminate elements by moving from elements that were originally in that range.

```
template<class InputIterator, class OutputIterator, class T>
  OutputIterator
    remove_copy(InputIterator first, InputIterator last,
                OutputIterator result, const T& value);

template<class InputIterator, class OutputIterator, class Predicate>
  OutputIterator
    remove_copy_if(InputIterator first, InputIterator last,
                   OutputIterator result, Predicate pred);
```

1 *Requires:* The ranges `[first,last)` and `[result,result + (last - first))` shall not overlap. The expression `*result = *first` shall be valid.

2 *Effects:* Copies all the elements referred to by the iterator `i` in the range `[first,last)` for which the following corresponding conditions do not hold: `*i == value, pred(*i) != false`.

3 *Returns:* The end of the resulting range.

4 *Complexity:* Exactly `last - first` applications of the corresponding predicate.

5 *Remarks:* Stable (17.602.0.1).

25.90.1 Unique [alg.unique]

```
template<class ForwardIterator>
  ForwardIterator unique(ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
  ForwardIterator unique(ForwardIterator first, ForwardIterator last,
                         BinaryPredicate pred);
```

1

Effects: For a nonempty range, eliminates all but the first element from every consecutive group of equivalent elements referred to by the iterator `i` in the range `[first + 1,last)` for which the following conditions hold: `*(i - 1) == *i` or `pred(*(i - 1), *i) != false`.

1 *Requires:* The comparison function shall be an equivalence relation. The type of `*first` shall satisfy the `MoveAssignable` requirements (Table 22).

2 *Returns:* The end of the resulting range.

3 *Complexity:* For nonempty ranges, exactly `(last - first) - 1` applications of the corresponding predicate.

```
template<class InputIterator, class OutputIterator>
  OutputIterator
    unique_copy(InputIterator first, InputIterator last,
                OutputIterator result);

template<class InputIterator, class OutputIterator,
         class BinaryPredicate>
  OutputIterator
    unique_copy(InputIterator first, InputIterator last,
                OutputIterator result, BinaryPredicate pred);
```

4 *Requires:* The comparison function shall be an equivalence relation. The ranges `[first,last)` and `[result,result+(last-first))` shall not overlap. The expression `*result = *first` shall be valid. If neither `InputIterator` nor `OutputIterator` meets the requirements of forward iterator then the value type of `InputIterator` shall be `CopyConstructible` (Table 21) and `CopyAssignable` (Table 23). Otherwise `CopyConstructible` is not required.

5 *Effects:* Copies only the first element from every consecutive group of equal elements referred to by the iterator `i` in the range `[first,last)` for which the following corresponding conditions hold: `*i == *(i - 1)` or `pred(*i, *(i - 1)) != false`.

6 *Returns:* The end of the resulting range.

7 *Complexity:* For nonempty ranges, exactly `last - first - 1` applications of the corresponding predicate.

25.93.1 Reverse [alg.reverse]

```
template<class BidirectionalIterator>
  void reverse(BidirectionalIterator first, BidirectionalIterator last);
```

1

Effects: For each non-negative integer `i < (last - first)/2`, applies `iter_swap` to all pairs of iterators `first + i, (last - i) - 1`.

1 *Requires:* `*first` shall be swappable (17.143.0.1).

2 *Complexity:* Exactly `(last - first)/2` swaps.

```
template<class BidirectionalIterator, class OutputIterator>
  OutputIterator
    reverse_copy(BidirectionalIterator first,
                 BidirectionalIterator last, OutputIterator result);
```

3

Effects: Copies the range `[first,last)` to the range `[result,result+(last-first))` such that for every non-negative integer `i < (last - first)` the following assignment takes place: `*(result + (last - first) - 1 - i) = *(first + i)`.

1 *Requires:* The ranges `[first,last)` and `[result,result+(last-first))` shall not overlap.

2 *Returns:* `result + (last - first)`.

3 *Complexity:* Exactly `last - first` assignments.

25.95.1 Rotate [alg.rotate]

```
template<class ForwardIterator>
  ForwardIterator rotate(ForwardIterator first, ForwardIterator middle,
              ForwardIterator last);
```

1 *Effects:* For each non-negative integer `i < (last - first)`, places the element from the position `first + i` into position `first + (i + (last - middle)) % (last - first)`.

2 *Returns:* `first + (last - middle)`.

3 *Remarks:* This is a left rotate.

4 *Requires:* `[first,middle)` and `[middle,last)` shall be valid ranges. `ForwardIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type of `*first` shall satisfy the requirements of `MoveConstructible` (Table 20) and the requirements of `MoveAssignable` (Table 22).

5

Complexity: At most `last - first` swaps.

```
template<class ForwardIterator, class OutputIterator>
  OutputIterator
    rotate_copy(ForwardIterator first, ForwardIterator middle,
                ForwardIterator last, OutputIterator result);
```

1 *Effects:* Copies the range `[first,last)` to the range `[result,result + (last - first))` such that for each non-negative integer `i < (last - first)` the following assignment takes place: `*(result + i) = *(first + (i + (middle - first)) % (last - first))`.

2 *Returns:* `result + (last - first)`.

3 *Requires:* The ranges `[first,last)` and `[result,result + (last - first))` shall not overlap.

4 *Complexity:* Exactly `last - first` assignments.

25.96.1 Shuffle [alg.random.shuffle]

```
template<class RandomAccessIterator, class UniformRandomNumberGenerator>
  void shuffle(RandomAccessIterator first,
                      RandomAccessIterator last,
                      UniformRandomNumberGenerator&& g);
```

1 *Effects:* Permutes the elements in the range `[first,last)` such that each possible permutation of those elements has equal probability of appearance.

2 *Requires:* `RandomAccessIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type `UniformRandomNumberGenerator` shall meet the requirements of a uniform random number generator (26.75.0.1) type whose return type is convertible to `iterator_traits<RandomAccessIterator>::difference_type`.

3 *Complexity:* Exactly `(last - first) - 1` swaps.

4 *Remarks:* To the extent that the implementation of this function makes use of random numbers, the object `g` shall serve as the implementation's source of randomness.

25.96.2 Partitions [alg.partitions]

```
template <class InputIterator, class Predicate>
  bool is_partitioned(InputIterator first, InputIterator last, Predicate pred);
```

1 *Requires:* `InputIterator`'s value type shall be convertible to `Predicate`'s argument type.

2 *Returns:* `true` if `[first,last)` is empty or if `[first,last)` is partitioned by `pred`, i.e. if all elements that satisfy `pred` appear before those that do not.

3 *Complexity:* Linear. At most `last - first` applications of `pred`.

```
template<class ForwardIterator, class Predicate>
  ForwardIterator
    partition(ForwardIterator first,
              ForwardIterator last, Predicate pred);
```

4 *Effects:* Places all the elements in the range `[first,last)` that satisfy `pred` before all the elements that do not satisfy it.

5 *Returns:* An iterator `i` such that for every iterator `j` in the range `[first,i) pred(*j) != false`, and for every iterator `k` in the range `[i,last)`, `pred(*k) == false`.

1 *Requires:* `ForwardIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1).

2 *Complexity:* If ForwardIterator meets the requirements for a BidirectionalIterator, at most `(last - first) / 2` swaps are done; otherwise at most `last - first` swaps are done. Exactly `last - first` applications of the predicate are done.

```
template<class BidirectionalIterator, class Predicate>
  BidirectionalIterator
    stable_partition(BidirectionalIterator first,
                     BidirectionalIterator last, Predicate pred);
```

3 *Effects:* Places all the elements in the range `[first,last)` that satisfy `pred` before all the elements that do not satisfy it.

4 *Returns:* An iterator `i` such that for every iterator `j` in the range `[first,i)`, `pred(*j) != false`, and for every iterator `k` in the range `[i,last)`, `pred(*k) == false`. The relative order of the elements in both groups is preserved.

5 *Requires:* `BidirectionalIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type of `*first` shall satisfy the requirements of `MoveConstructible` (Table 20) and of `MoveAssignable` (Table 22).

6 *Complexity:* At most `(last - first) * log(last - first)` swaps, but only linear number of swaps if there is enough extra memory. Exactly `last - first` applications of the predicate.

```
template <class InputIterator, class OutputIterator1,
          class OutputIterator2, class Predicate>
  pair<OutputIterator1, OutputIterator2>
  partition_copy(InputIterator first, InputIterator last,
                 OutputIterator1 out_true, OutputIterator2 out_false,
                 Predicate pred);
```

7 *Requires:* `InputIterator`'s value type shall be `CopyAssignable`, and shall be writable to the `out_true` and `out_false` `OutputIterator`s, and shall be convertible to `Predicate`'s argument type. The input range shall not overlap with either of the output ranges.

8 *Effects:* For each iterator `i` in `[first,last)`, copies `*i` to the output range beginning with `out_true` if `pred(*i)` is `true`, or to the output range beginning with `out_false` otherwise.

9 *Returns:* A pair `p` such that `p.first` is the end of the output range beginning at `out_true` and `p.second` is the end of the output range beginning at `out_false`.

10 *Complexity:* Exactly `last - first` applications of `pred`.

```
template<class ForwardIterator, class Predicate>
  ForwardIterator partition_point(ForwardIterator first,
                                  ForwardIterator last,
                                  Predicate pred);
```

11 *Requires:* `ForwardIterator`'s value type shall be convertible to `Predicate`'s argument type. `[first, last)` shall be partitioned by `pred`, i.e. all elements that satisfy `pred` shall appear before those that do not.

12 *Returns:* An iterator `mid` such that `all_of(first, mid, pred)` and `none_of(mid, last, pred)` are both true.

13 *Complexity:* $\mathcal{O}(log(last - first))$ applications of `pred`.

25.98 Sorting and related operations [alg.sorting]

1

All the operations in 25.98 have two versions: one that takes a function object of type `Compare` and one that uses an `operator<`.

1

`Compare` is a function object type (20.283). The return value of the function call operation applied to an object of type `Compare`, when contextually converted to `bool` (Clause 4), yields `true` if the first argument of the call is less than the second, and `false` otherwise. `Compare comp` is used throughout for algorithms assuming an ordering relation. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.

1

For all algorithms that take `Compare`, there is a version that uses `operator<` instead. That is, `comp(*i, *j) != false` defaults to `*i < *j != false`. For algorithms other than those described in 25.160.1 to work correctly, `comp` has to induce a strict weak ordering on the values.

1

The term *strict* refers to the requirement of an irreflexive relation (`!comp(x, x)` for all `x`), and the term *weak* to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define `equiv(a, b)` as `!comp(a, b) && !comp(b, a)`, then the requirements are that `comp` and `equiv` both be transitive relations:

— `comp(a, b) && comp(b, c)` implies `comp(a, c)`

— `equiv(a, b) && equiv(b, c)` implies `equiv(a, c)` [*Note:* Under these conditions, it can be shown that

  — `equiv` is an equivalence relation

  — `comp` induces a well-defined relation on the equivalence classes determined by `equiv`

  — The induced relation is a strict total ordering. — *end note*]

1 A sequence is *sorted with respect to a comparator* `comp` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, `comp(*(i + n), *i) == false`.

2 A sequence `[start,finish)` is *partitioned with respect to an expression* `f(e)` if there exists an integer `n` such that for all `0 <= i < distance(start, finish)`, `f(*(start + i))` is true if and only if `i < n`.

3 In the descriptions of the functions that deal with ordering relationships we frequently use a notion of equivalence to describe concepts such as stability. The equivalence to which we refer is not necessarily an `operator==`, but an equivalence relation induced by the strict weak ordering. That is, two elements `a` and `b` are considered equivalent if and only if `!(a < b) && !(b < a)`.

25.144.1 Sorting [alg.sort]

25.144.1.1 `sort` [sort]

```
template<class RandomAccessIterator>
  void sort(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
  void sort(RandomAccessIterator first, RandomAccessIterator last,
            Compare comp);
```

1 *Effects:* Sorts the elements in the range `[first,last)`.

2 *Requires:* `RandomAccessIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type of `*first` shall satisfy the requirements of `MoveConstructible` (Table 20) and of `MoveAssignable` (Table 22).

1 *Complexity:* $\mathcal{O}(N \log(N))$ (where N `== last - first`) comparisons.

25.154.0.1 `stable_sort` [stable.sort]

```
template<class RandomAccessIterator>
  void stable_sort(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
  void stable_sort(RandomAccessIterator first, RandomAccessIterator last,
                   Compare comp);
```

1 *Effects:* Sorts the elements in the range `[first,last)`.

2 *Requires:* `RandomAccessIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type of `*first` shall satisfy the requirements of `MoveConstructible` (Table 20) and of `MoveAssignable` (Table 22).

3 *Complexity:* It does at most $N \log^2(N)$ (where N `== last - first`) comparisons; if enough extra memory is available, it is $N \log(N)$.

1 *Remarks:* Stable (17.602.0.1).

25.156.0.1 `partial_sort` [partial.sort]

```
template<class RandomAccessIterator>
  void partial_sort(RandomAccessIterator first,
                    RandomAccessIterator middle,
                    RandomAccessIterator last);
```

```
template<class RandomAccessIterator, class Compare>
  void partial_sort(RandomAccessIterator first,
                    RandomAccessIterator middle,
                    RandomAccessIterator last,
                    Compare comp);
```

1

Effects: Places the first `middle - first` sorted elements from the range `[first,last)` into the range `[first,middle)`. The rest of the elements in the range `[middle,last)` are placed in an unspecified order.

1 *Requires:* `RandomAccessIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type of `*first` shall satisfy the requirements of `MoveConstructible` (Table 20) and of `MoveAssignable` (Table 22).

2

Complexity: It takes approximately `(last - first) * log(middle - first)` comparisons.

25.158.0.1 `partial_sort_copy` [partial.sort.copy]

```
template<class InputIterator, class RandomAccessIterator>
  RandomAccessIterator
    partial_sort_copy(InputIterator first, InputIterator last,
                      RandomAccessIterator result_first,
                      RandomAccessIterator result_last);

template<class InputIterator, class RandomAccessIterator,
         class Compare>
  RandomAccessIterator
    partial_sort_copy(InputIterator first, InputIterator last,
                      RandomAccessIterator result_first,
                      RandomAccessIterator result_last,
                      Compare comp);
```

1 *Effects:* Places the first `min(last - first, result_last - result_first)` sorted elements into the range `[result_first,result_first + min(last - first, result_last - result_first))`.

2 *Returns:* The smaller of: `result_last` or `result_first + (last - first)`.

3 *Requires:* `RandomAccessIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type of `*result_first` shall satisfy the requirements of `MoveConstructible` (Table 20) and of `MoveAssignable` (Table 22).

4 *Complexity:* Approximately `(last - first) * log(min(last - first, result_last - result_first))` comparisons.

25.158.0.2 `is_sorted` [is.sorted]

```
template<class ForwardIterator>
  bool is_sorted(ForwardIterator first, ForwardIterator last);
```

1 *Returns:* `is_sorted_until(first, last) == last`

```
template<class ForwardIterator, class Compare>
  bool is_sorted(ForwardIterator first, ForwardIterator last,
    Compare comp);
```

2 *Returns:* `is_sorted_until(first, last, comp) == last`

```
template<class ForwardIterator>
  ForwardIterator is_sorted_until(ForwardIterator first, ForwardIterator last);
template<class ForwardIterator, class Compare>
  ForwardIterator is_sorted_until(ForwardIterator first, ForwardIterator last,
    Compare comp);
```

3 *Returns:* If `distance(first, last) < 2`, returns `last`. Otherwise, returns the last iterator `i` in `[first,last]` for which the range `[first,i)` is sorted.

4 *Complexity:* Linear.

25.158.1 Nth element [alg.nth.element]

```
template<class RandomAccessIterator>
  void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
                   RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
  void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
                   RandomAccessIterator last,  Compare comp);
```

1

After `nth_element` the element in the position pointed to by `nth` is the element that would be in that position if the whole range were sorted, unless `nth == last`. Also for every iterator `i` in the range `[first,nth)` and every iterator `j` in the range `[nth,last)` it holds that: `!(*j < *i)` or `comp(*j, *i) == false`.

1 *Requires:* `RandomAccessIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type of `*first` shall satisfy the requirements of `MoveConstructible` (Table 20) and of `MoveAssignable` (Table 22).

2 *Complexity:* Linear on average.

25.160.1 Binary search [alg.binary.search]

1

All of the algorithms in this section are versions of binary search and assume that the sequence being searched is partitioned with respect to an expression formed by binding the search key to an argument of the implied or explicit comparison function. They work on non-random access iterators minimizing the number of comparisons, which will be logarithmic for all types of iterators. They are especially appropriate for random access iterators, because these algorithms do a logarithmic number of steps through the data structure. For non-random access iterators they execute a linear number of steps.

25.163.0.1 `lower_bound` [lower.bound]

```
template<class ForwardIterator, class T>
  ForwardIterator
    lower_bound(ForwardIterator first, ForwardIterator last,
                const T& value);

template<class ForwardIterator, class T, class Compare>
  ForwardIterator
    lower_bound(ForwardIterator first, ForwardIterator last,
                const T& value, Compare comp);
```

1

Requires: The elements `e` of `[first,last)` shall be partitioned with respect to the expression `e < value` or `comp(e, value)`.

1

Returns: The furthermost iterator `i` in the range `[first,last]` such that for every iterator `j` in the range `[first,i)` the following corresponding conditions hold: `*j < value` or `comp(*j, value) != false`.

1 *Complexity:* At most $\log_2$(`last - first`) + $\mathcal{O}(1)$ comparisons.

25.173.0.1 `upper_bound` [upper.bound]

```
template<class ForwardIterator, class T>
  ForwardIterator
    upper_bound(ForwardIterator first, ForwardIterator last,
                const T& value);

template<class ForwardIterator, class T, class Compare>
  ForwardIterator
    upper_bound(ForwardIterator first, ForwardIterator last,
                const T& value, Compare comp);
```

1

Requires: The elements `e` of `[first,last)` shall be partitioned with respect to the expression `!(value < e)` or `!comp(value, e)`.

1

Returns: The furthermost iterator `i` in the range `[first,last]` such that for every iterator `j` in the range `[first,i)` the following corresponding conditions hold: `!(value < *j)` or `comp(value, *j) == false`.

1 *Complexity:* At most $\log_2$(`last - first`) + $\mathcal{O}(1)$ comparisons.

25.178.0.1 `equal_range` [equal.range]

```
template<class ForwardIterator, class T>
  pair<ForwardIterator, ForwardIterator>
    equal_range(ForwardIterator first,
                ForwardIterator last, const T& value);

template<class ForwardIterator, class T, class Compare>
  pair<ForwardIterator, ForwardIterator>
    equal_range(ForwardIterator first,
                ForwardIterator last, const T& value,
                Compare comp);
```

1

Requires: The elements `e` of `[first,last)` shall be partitioned with respect to the expressions `e < value` and `!(value < e)` or `comp(e, value)` and `!comp(value, e)`. Also, for all elements `e` of `[first, last)`, `e < value` shall imply `!(value < e)` or `comp(e, value)` shall imply `!comp(value, e)`.

1 *Returns:*

```
make_pair(lower_bound(first, last, value),
          upper_bound(first, last, value))
```

or

```
make_pair(lower_bound(first, last, value, comp),
          upper_bound(first, last, value, comp))
```

2 *Complexity:* At most $2 * \log_2$(`last - first`) + $\mathcal{O}(1)$ comparisons.

25.179.0.1 `binary_search` [binary.search]

```
template<class ForwardIterator, class T>
  bool binary_search(ForwardIterator first, ForwardIterator last,
                     const T& value);

template<class ForwardIterator, class T, class Compare>
  bool binary_search(ForwardIterator first, ForwardIterator last,
                     const T& value, Compare comp);
```

1 *Requires:* The elements `e` of `[first,last)` are partitioned with respect to the expressions `e < value` and `!(value < e)` or `comp(e, value)` and `!comp(value, e)`. Also, for all elements `e` of `[first, last)`, `e < value` implies `!(value < e)` or `comp(e, value)` implies `!comp(value, e)`.

1 *Returns:* `true` if there is an iterator `i` in the range `[first,last)` that satisfies the corresponding conditions: `!(*i < value) && !(value < *i)` or `comp(*i, value) == false && comp(value, *i) == false`.

1 *Complexity:* At most $\log_2$(`last - first`) + $\mathcal{O}(1)$ comparisons.

25.182.1 Merge [alg.merge]

```
template<class InputIterator1, class InputIterator2,
         class OutputIterator>
  OutputIterator
    merge(InputIterator1 first1, InputIterator1 last1,
          InputIterator2 first2, InputIterator2 last2,
          OutputIterator result);

template<class InputIterator1, class InputIterator2,
         class OutputIterator, class Compare>
  OutputIterator
    merge(InputIterator1 first1, InputIterator1 last1,
          InputIterator2 first2, InputIterator2 last2,
          OutputIterator result, Compare comp);
```

1 *Effects:* Copies all the elements of the two ranges `[first1,last1)` and `[first2,last2)` into the range `[result,result_last)`, where `result_last` is `result + (last1 - first1) + (last2 - first2)`, such that the resulting range satisfies `is_sorted(result, result_last)` or `is_sorted(result, result_last, comp)`, respectively.

2 *Requires:* The ranges `[first1,last1)` and `[first2,last2)` shall be sorted with respect to `operator<` or `comp`. The resulting range shall not overlap with either of the original ranges.

1 *Returns:* `result + (last1 - first1) + (last2 - first2)`.

2 *Complexity:* At most `(last1 - first1) + (last2 - first2) - 1` comparisons.

1 *Remarks:* Stable (17.602.0.1).

```
template<class BidirectionalIterator>
  void inplace_merge(BidirectionalIterator first,
                     BidirectionalIterator middle,
                     BidirectionalIterator last);

template<class BidirectionalIterator, class Compare>
  void inplace_merge(BidirectionalIterator first,
                     BidirectionalIterator middle,
                     BidirectionalIterator last, Compare comp);
```

1 *Effects:* Merges two sorted consecutive ranges `[first,middle)` and `[middle,last)`, putting the result of the merge into the range `[first,last)`. The resulting range will be in non-decreasing order; that is, for every iterator `i` in `[first,last)` other than `first`, the condition `*i < *(i - 1)` or, respectively, `comp(*i, *(i - 1))` will be false.

2 *Requires:* The ranges `[first,middle)` and `[middle,last)` shall be sorted with respect to `operator<` or `comp`. `BidirectionalIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type of `*first` shall satisfy the requirements of `MoveConstructible` (Table 20) and of `MoveAssignable` (Table 22).

3 *Complexity:* When enough additional memory is available, `(last - first) - 1` comparisons. If no additional memory is available, an algorithm with complexity $N \log(N)$ (where `N` is equal to `last - first`) may be used.

1 *Remarks:* Stable (17.602.0.1).

25.189.1 Set operations on sorted structures [alg.set.operations]

1 This section defines all the basic set operations on sorted structures. They also work with `multisets` (23.931.1) containing multiple copies of equivalent elements. The semantics of the set operations are generalized to `multisets` in a standard way by defining `set_union()` to contain the maximum number of occurrences of every element, `set_intersection()` to contain the minimum, and so on.

25.194.0.1 `includes` [includes]

```
template<class InputIterator1, class InputIterator2>
  bool includes(InputIterator1 first1, InputIterator1 last1,
                InputIterator2 first2, InputIterator2 last2);

template<class InputIterator1, class InputIterator2, class Compare>
  bool includes(InputIterator1 first1, InputIterator1 last1,
                InputIterator2 first2, InputIterator2 last2,
                Compare comp);
```

1 *Returns:* `true` if `[first2,last2)` is empty or if every element in the range `[first2,last2)` is contained in the range `[first1,last1)`. Returns `false` otherwise.

2 *Complexity:* At most `2 * ((last1 - first1) + (last2 - first2)) - 1` comparisons.

25.194.0.2 `set_union` [set.union]

```
template<class InputIterator1, class InputIterator2,
         class OutputIterator>
  OutputIterator
    set_union(InputIterator1 first1, InputIterator1 last1,
              InputIterator2 first2, InputIterator2 last2,
```

```
              OutputIterator result);

template<class InputIterator1, class InputIterator2,
         class OutputIterator, class Compare>
  OutputIterator
    set_union(InputIterator1 first1, InputIterator1 last1,
              InputIterator2 first2, InputIterator2 last2,
              OutputIterator result, Compare comp);
```

1 *Effects:* Constructs a sorted union of the elements from the two ranges; that is, the set of elements that are present in one or both of the ranges.

2 *Requires:* The resulting range shall not overlap with either of the original ranges.

3 *Returns:* The end of the constructed range.

4 *Complexity:* At most `2 * ((last1 - first1) + (last2 - first2)) - 1` comparisons.

5 *Remarks:* If `[first1,last1)` contains m elements that are equivalent to each other and `[first2, last2)` contains n elements that are equivalent to them, then all m elements from the first range shall be copied to the output range, in order, and then $\max(n - m, 0)$ elements from the second range shall be copied to the output range, in order.

25.194.0.3 `set_intersection` [set.intersection]

```
template<class InputIterator1, class InputIterator2,
         class OutputIterator>
  OutputIterator
    set_intersection(InputIterator1 first1, InputIterator1 last1,
                     InputIterator2 first2, InputIterator2 last2,
                     OutputIterator result);

template<class InputIterator1, class InputIterator2,
         class OutputIterator, class Compare>
  OutputIterator
    set_intersection(InputIterator1 first1, InputIterator1 last1,
                     InputIterator2 first2, InputIterator2 last2,
                     OutputIterator result, Compare comp);
```

1 *Effects:* Constructs a sorted intersection of the elements from the two ranges; that is, the set of elements that are present in both of the ranges.

2 *Requires:* The resulting range shall not overlap with either of the original ranges.

3 *Returns:* The end of the constructed range.

4 *Complexity:* At most `2 * ((last1 - first1) + (last2 - first2)) - 1` comparisons.

5 *Remarks:* If `[first1,last1)` contains m elements that are equivalent to each other and `[first2, last2)` contains n elements that are equivalent to them, the first $\min(m, n)$ elements shall be copied from the first range to the output range, in order.

25.195.0.1 `set_difference` [set.difference]

```
template<class InputIterator1, class InputIterator2,
         class OutputIterator>
  OutputIterator
    set_difference(InputIterator1 first1, InputIterator1 last1,
                   InputIterator2 first2, InputIterator2 last2,
```

```
                    OutputIterator result);

template<class InputIterator1, class InputIterator2,
         class OutputIterator, class Compare>
  OutputIterator
    set_difference(InputIterator1 first1, InputIterator1 last1,
                   InputIterator2 first2, InputIterator2 last2,
                   OutputIterator result, Compare comp);
```

1 *Effects:* Copies the elements of the range `[first1,last1)` which are not present in the range `[first2, last2)` to the range beginning at `result`. The elements in the constructed range are sorted.

2 *Requires:* The resulting range shall not overlap with either of the original ranges.

3 *Returns:* The end of the constructed range.

4 *Complexity:* At most `2 * ((last1 - first1) + (last2 - first2)) - 1` comparisons.

5 *Remarks:* If `[first1,last1)` contains m elements that are equivalent to each other and `[first2, last2)` contains n elements that are equivalent to them, the last $\max(m-n, 0)$ elements from `[first1, last1)` shall be copied to the output range.

25.195.0.2 `set_symmetric_difference` [set.symmetric.difference]

```
template<class InputIterator1, class InputIterator2,
         class OutputIterator>
  OutputIterator
    set_symmetric_difference(InputIterator1 first1, InputIterator1 last1,
                             InputIterator2 first2, InputIterator2 last2,
                             OutputIterator result);

template<class InputIterator1, class InputIterator2,
         class OutputIterator, class Compare>
  OutputIterator
    set_symmetric_difference(InputIterator1 first1, InputIterator1 last1,
                             InputIterator2 first2, InputIterator2 last2,
                             OutputIterator result, Compare comp);
```

1 *Effects:* Copies the elements of the range `[first1,last1)` that are not present in the range `[first2, last2)`, and the elements of the range `[first2,last2)` that are not present in the range `[first1, last1)` to the range beginning at `result`. The elements in the constructed range are sorted.

2 *Requires:* The resulting range shall not overlap with either of the original ranges.

3 *Returns:* The end of the constructed range.

4 *Complexity:* At most `2 * ((last1 - first1) + (last2 - first2)) - 1` comparisons.

5 *Remarks:* If `[first1,last1)` contains m elements that are equivalent to each other and `[first2, last2)` contains n elements that are equivalent to them, then $|m-n|$ of those elements shall be copied to the output range: the last $m-n$ of these elements from `[first1,last1)` if $m > n$, and the last $n-m$ of these elements from `[first2,last2)` if $m < n$.

25.195.1 Heap operations [alg.heap.operations]

1

A *heap* is a particular organization of elements in a range between two random access iterators `[a,b)`. Its two key properties are:

(1) There is no element greater than `*a` in the range and

(2) `*a` may be removed by `pop_heap()`, or a new element added by `push_heap()`, in $\mathcal{O}(\log(N))$ time.

1 These properties make heaps useful as priority queues.

2 `make_heap()` converts a range into a heap and `sort_heap()` turns a heap into a sorted sequence.

25.196.0.1 `push_heap` [push.heap]

```
template<class RandomAccessIterator>
  void push_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
  void push_heap(RandomAccessIterator first, RandomAccessIterator last,
                 Compare comp);
```

1 *Effects:* Places the value in the location `last - 1` into the resulting heap `[first,last)`.

2 *Requires:* The range `[first,last - 1)` shall be a valid heap. The type of `*first` shall satisfy the `MoveConstructible` requirements (Table 20) and the `MoveAssignable` requirements (Table 22).

3 *Complexity:* At most `log(last - first)` comparisons.

25.198.0.1 `pop_heap` [pop.heap]

```
template<class RandomAccessIterator>
  void pop_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
  void pop_heap(RandomAccessIterator first, RandomAccessIterator last,
                Compare comp);
```

1 *Requires:* The range `[first,last)` shall be a valid non-empty heap. `RandomAccessIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type of `*first` shall satisfy the requirements of `MoveConstructible` (Table 20) and of `MoveAssignable` (Table 22).

2 *Effects:* Swaps the value in the location `first` with the value in the location `last - 1` and makes `[first,last - 1)` into a heap.

1 *Complexity:* At most `2 * log(last - first)` comparisons.

25.199.0.1 `make_heap` [make.heap]

```
template<class RandomAccessIterator>
  void make_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
  void make_heap(RandomAccessIterator first, RandomAccessIterator last,
                 Compare comp);
```

1 *Effects:* Constructs a heap out of the range `[first,last)`.

2 *Requires:* The type of `*first` shall satisfy the `MoveConstructible` requirements (Table 20) and the `MoveAssignable` requirements (Table 22).

3 *Complexity:* At most `3 * (last - first)` comparisons.

25.199.0.2 `sort_heap` [sort.heap]

```
template<class RandomAccessIterator>
  void sort_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
  void sort_heap(RandomAccessIterator first, RandomAccessIterator last,
                 Compare comp);
```

1 *Effects:* Sorts elements in the heap `[first,last)`.

2 *Requires:* The range `[first,last)` shall be a valid heap. `RandomAccessIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The type of `*first` shall satisfy the requirements of `MoveConstructible` (Table 20) and of `MoveAssignable` (Table 22).

3 *Complexity:* At most $N \log(N)$ comparisons (where `N == last - first`).

25.199.0.3 `is_heap` [is.heap]

```
template<class RandomAccessIterator>
  bool is_heap(RandomAccessIterator first, RandomAccessIterator last);
```

1 *Returns:* `is_heap_until(first, last) == last`

```
template<class RandomAccessIterator, class Compare>
  bool is_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

1 *Returns:* `is_heap_until(first, last, comp) == last`

```
template<class RandomAccessIterator>
  RandomAccessIterator is_heap_until(RandomAccessIterator first, RandomAccessIterator last);
template<class RandomAccessIterator, class Compare>
  RandomAccessIterator is_heap_until(RandomAccessIterator first, RandomAccessIterator last,
    Compare comp);
```

2 *Returns:* If `distance(first, last) < 2`, returns `last`. Otherwise, returns the last iterator `i` in `[first,last]` for which the range `[first,i)` is a heap.

3 *Complexity:* Linear.

25.201.1 Minimum and maximum [alg.min.max]

```
template<class T> constexpr const T& min(const T& a, const T& b);
template<class T, class Compare>
  constexpr const T& min(const T& a, const T& b, Compare comp);
```

1 *Requires:* Type `T` is `LessThanComparable` (Table 18).

2 *Returns:* The smaller value.

3 *Remarks:* Returns the first argument when the arguments are equivalent.

```
template<class T>
  constexpr T min(initializer_list<T> t);
template<class T, class Compare>
  constexpr T min(initializer_list<T> t, Compare comp);
```

1 *Requires:* `T` is `LessThanComparable` and `CopyConstructible` and `t.size() > 0`.

2 *Returns:* The smallest value in the initializer_list.

3 *Remarks:* Returns a copy of the leftmost argument when several arguments are equivalent to the smallest.

```
template<class T> constexpr const T& max(const T& a, const T& b);
template<class T, class Compare>
  constexpr const T& max(const T& a, const T& b, Compare comp);
```

1 *Requires:* Type `T` is `LessThanComparable` (Table 18).

2 *Returns:* The larger value.

3 *Remarks:* Returns the first argument when the arguments are equivalent.

```
template<class T>
  constexpr T max(initializer_list<T> t);
template<class T, class Compare>
  constexpr T max(initializer_list<T> t, Compare comp);
```

4 *Requires:* `T` is `LessThanComparable` and `CopyConstructible` and `t.size() > 0`.

5 *Returns:* The largest value in the initializer_list.

6 *Remarks:* Returns a copy of the leftmost argument when several arguments are equivalent to the largest.

```
template<class T> constexpr pair<const T&, const T&> minmax(const T& a, const T& b);
template<class T, class Compare>
  constexpr pair<const T&, const T&> minmax(const T& a, const T& b, Compare comp);
```

7 *Requires:* Type `T` shall be `LessThanComparable` (Table 18).

8 *Returns:* `pair<const T&, const T&>(b, a)` if `b` is smaller than `a`, and `pair<const T&, const T&>(a, b)` otherwise.

9 *Remarks:* Returns `pair<const T&, const T&>(a, b)` when the arguments are equivalent.

10 *Complexity:* Exactly one comparison.

```
template<class T>
  constexpr pair<T, T> minmax(initializer_list<T> t);
template<class T, class Compare>
  constexpr pair<T, T> minmax(initializer_list<T> t, Compare comp);
```

11 *Requires:* `T` is `LessThanComparable` and `CopyConstructible` and `t.size() > 0`.

12 *Returns:* `pair<T, T>(x, y)`, where `x` has the smallest and `y` has the largest value in the initializer list.

13 *Remarks:* `x` is a copy of the leftmost argument when several arguments are equivalent to the smallest. `y` is a copy of the rightmost argument when several arguments are equivalent to the largest.

14 *Complexity:* At most `(3/2) * t.size()` applications of the corresponding predicate.

```
template<class ForwardIterator>
  ForwardIterator min_element(ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
  ForwardIterator min_element(ForwardIterator first, ForwardIterator last,
                              Compare comp);
```

15

Returns: The first iterator `i` in the range `[first,last)` such that for every iterator `j` in the range `[first,last)` the following corresponding conditions hold: `!(*j < *i)` or `comp(*j, *i) == false`. Returns `last` if `first == last`.

1 *Complexity:* Exactly `max((last - first) - 1, 0)` applications of the corresponding comparisons.

```
template<class ForwardIterator>
  ForwardIterator max_element(ForwardIterator first, ForwardIterator last);
template<class ForwardIterator, class Compare>
  ForwardIterator max_element(ForwardIterator first, ForwardIterator last,
                              Compare comp);
```

2 *Returns:* The first iterator `i` in the range `[first,last)` such that for every iterator `j` in the range `[first,last)` the following corresponding conditions hold: `!(*i < *j)` or `comp(*i, *j) == false`. Returns `last` if `first == last`.

3 *Complexity:* Exactly `max((last - first) - 1, 0)` applications of the corresponding comparisons.

```
template<class ForwardIterator>
  pair<ForwardIterator, ForwardIterator>
    minmax_element(ForwardIterator first, ForwardIterator last);
template<class ForwardIterator, class Compare>
  pair<ForwardIterator, ForwardIterator>
    minmax_element(ForwardIterator first, ForwardIterator last, Compare comp);
```

4 *Returns:* `make_pair(first, first)` if `[first,last)` is empty, otherwise `make_pair(m, M)`, where `m` is the first iterator in `[first,last)` such that no iterator in the range refers to a smaller element, and where `M` is the last iterator in `[first,last)` such that no iterator in the range refers to a larger element.

5 *Complexity:* At most $max(\lfloor \frac{3}{2}(N-1) \rfloor, 0)$ applications of the corresponding predicate, where N is `distance(first, last)`.

25.204.1 Lexicographical comparison [alg.lex.comparison]

```
template<class InputIterator1, class InputIterator2>
  bool
    lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
                            InputIterator2 first2, InputIterator2 last2);

template<class InputIterator1, class InputIterator2, class Compare>
  bool
    lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
                            InputIterator2 first2, InputIterator2 last2,
                            Compare comp);
```

1 *Returns:* `true` if the sequence of elements defined by the range `[first1,last1)` is lexicographically less than the sequence of elements defined by the range `[first2,last2)` and `false` otherwise.

2 *Complexity:* At most `2*min((last1 - first1), (last2 - first2))` applications of the corresponding comparison.

3 *Remarks:* If two sequences have the same number of elements and their corresponding elements are equivalent, then neither sequence is lexicographically less than the other. If one sequence is a prefix of the other, then the shorter sequence is lexicographically less than the longer sequence. Otherwise, the lexicographical comparison of the sequences yields the same result as the comparison of the first corresponding pair of elements that are not equivalent.

```
for ( ; first1 != last1 && first2 != last2 ; ++first1, ++first2) {
  if (*first1 < *first2) return true;
  if (*first2 < *first1) return false;
}
return first1 == last1 && first2 != last2;
```

4 *Remarks:* An empty sequence is lexicographically less than any non-empty sequence, but not less than any empty sequence.

25.204.2 Permutation generators [alg.permutation.generators]

```
template<class BidirectionalIterator>
  bool next_permutation(BidirectionalIterator first,
                        BidirectionalIterator last);

template<class BidirectionalIterator, class Compare>
  bool next_permutation(BidirectionalIterator first,
                        BidirectionalIterator last, Compare comp);
```

1 *Effects:* Takes a sequence defined by the range `[first,last)` and transforms it into the next permutation. The next permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to `operator<` or `comp`. If such a permutation exists, it returns `true`. Otherwise, it transforms the sequence into the smallest permutation, that is, the ascendingly sorted one, and returns `false`.

2 *Requires:* `BidirectionalIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1).

3 *Complexity:* At most `(last - first)/2` swaps.

```
template<class BidirectionalIterator>
  bool prev_permutation(BidirectionalIterator first,
                        BidirectionalIterator last);

template<class BidirectionalIterator, class Compare>
  bool prev_permutation(BidirectionalIterator first,
                        BidirectionalIterator last, Compare comp);
```

4 *Effects:* Takes a sequence defined by the range `[first,last)` and transforms it into the previous permutation. The previous permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to `operator<` or `comp`.

5 *Returns:* `true` if such a permutation exists. Otherwise, it transforms the sequence into the largest permutation, that is, the descendingly sorted one, and returns `false`.

6 *Requires:* `BidirectionalIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1).

7 *Complexity:* At most `(last - first)/2` swaps.

25.205 C library algorithms [alg.c.library]

1 Table 113 describes some of the contents of the header `<cstdlib>`.

Table 113 — Header `<cstdlib>` synopsis

Type	Name(s)
Type:	`size_t`
Functions:	`bsearch` `qsort`

2

The contents are the same as the Standard C library header `<stdlib.h>` with the following exceptions:

1

The function signature:

```
bsearch(const void *, const void *, size_t, size_t,
  int (*)(const void *, const void *));
```

is replaced by the two declarations:

```
extern "C" void* bsearch(const void* key, const void* base,
                         size_t nmemb, size_t size,
                         int (*compar)(const void*, const void*));
extern "C++" void* bsearch(const void* key, const void* base,
                           size_t nmemb, size_t size,
                           int (*compar)(const void*, const void*));
```

both of which have the same behavior as the original declaration.

1 The function signature:

```
qsort(void *, size_t, size_t,
  int (*)(const void *, const void *));
```

is replaced by the two declarations:

```
extern "C" void qsort(void* base, size_t nmemb, size_t size,
                      int (*compar)(const void*, const void*));
extern "C++" void qsort(void* base, size_t nmemb, size_t size,
                        int (*compar)(const void*, const void*));
```

both of which have the same behavior as the original declaration. The behavior is undefined unless the objects in the array pointed to by `base` are of trivial type.

[*Note:* Because the function argument `compar()` may throw an exception, `bsearch()` and `qsort()` are allowed to propagate the exception (17.677.0.1). — *end note*]

See also: ISO C 7.10.5.

26 Numerics library [numerics]

26.1 General [numerics.general]

1 This Clause describes components that C++ programs may use to perform seminumerical operations.

2 The following subclauses describe components for complex number types, random number generation, numeric (n-at-a-time) arrays, generalized numeric algorithms, and facilities included from the ISO C library, as summarized in Table 114.

Table 114 — Numerics library summary

Subclause		Header(s)
26.2	Requirements	
26.5	Floating-Point Environment	`<cfenv>`
26.11	Complex Numbers	`<complex>`
26.45	Random number generation	`<random>`
26.129	Numeric arrays	`<valarray>`
26.144	Generalized numeric operations	`<numeric>`

26.149	C library	`<cmath>`
		`<ctgmath>`
		`<tgmath.h>`
		`<cstdlib>`

26.2 Numeric type requirements [numeric.requirements]

1 The `complex` and `valarray` components are parameterized by the type of information they contain and manipulate. A C++ program shall instantiate these components only with a type `T` that satisfies the following requirements:[272]

(1.1) — `T` is not an abstract class (it has no pure virtual member functions);

(1.2) — `T` is not a reference type;

(1.3) — `T` is not cv-qualified;

(1.4) — If `T` is a class, it has a public default constructor;

(1.5) — If `T` is a class, it has a public copy constructor with the signature `T::T(const T&)`

(1.6) — If `T` is a class, it has a public destructor;

(1.7) — If `T` is a class, it has a public assignment operator whose signature is either `T& T::operator=(const T&)` or `T& T::operator=(T)`

(1.8) — If `T` is a class, its assignment operator, copy and default constructors, and destructor shall correspond to each other in the following sense: Initialization of raw storage using the default constructor, followed by assignment, is semantically equivalent to initialization of raw storage using the copy constructor.

272) In other words, value types. These include arithmetic types, pointers, the library class `complex`, and instantiations of `valarray` for value types.

Destruction of an object, followed by initialization of its raw storage using the copy constructor, is semantically equivalent to assignment to the original object.

[*Note:* This rule states that there shall not be any subtle differences in the semantics of initialization versus assignment. This gives an implementation considerable flexibility in how arrays are initialized.

[*Example:* An implementation is allowed to initialize a `valarray` by allocating storage using the `new` operator (which implies a call to the default constructor for each element) and then assigning each element its value. Or the implementation can allocate raw storage and use the copy constructor to initialize each element. — *end example*]

If the distinction between initialization and assignment is important for a class, or if it fails to satisfy any of the other conditions listed above, the programmer should use `vector` (23.696.1) instead of `valarray` for that class; — *end note*]

(1.9) — If `T` is a class, it does not overload unary `operator&`.

2 If any operation on `T` throws an exception the effects are undefined.

3

In addition, many member and related functions of `valarray<T>` can be successfully instantiated and will exhibit well-defined behavior if and only if `T` satisfies additional requirements specified for each such member or related function.

1

[*Example:* It is valid to instantiate `valarray<complex>`, but `operator>()` will not be successfully instantiated for `valarray<complex>` operands, since `complex` does not have any ordering operators. — *end example*]

26.5 The floating-point environment [cfenv]

26.5.1 Header `<cfenv>` synopsis [cfenv.syn]

```
namespace std {
  // types
  typedef object type  fenv_t;
  typedef integer type fexcept_t;

  // functions
  int feclearexcept(int except);
  int fegetexceptflag(fexcept_t* pflag, int except);
  int feraiseexcept(int except);
  int fesetexceptflag(const fexcept_t* pflag, int except);
  int fetestexcept(int except);

  int fegetround(void);
  int fesetround(int mode);

  int fegetenv(fenv_t* penv);
  int feholdexcept(fenv_t* penv);
  int fesetenv(const fenv_t* penv);
  int feupdateenv(const fenv_t* penv);
}
```

1 The header also defines the macros:

```
FE_ALL_EXCEPT
FE_DIVBYZERO
```

```
FE_INEXACT
FE_INVALID
FE_OVERFLOW
FE_UNDERFLOW

FE_DOWNWARD
FE_TONEAREST
FE_TOWARDZERO
FE_UPWARD

FE_DFL_ENV
```

2

The header defines all functions, types, and macros the same as Clause 7.6 of the C standard.

1

The floating-point environment has thread storage duration (3.2291.1). The initial state for a thread's floating-point environment is the state of the floating-point environment of the thread that constructs the corresponding `std::thread` object (30.25.1) at the time it constructed the object. [*Note:* That is, the child thread gets the floating-point state of the parent thread at the time of the child's creation. — *end note*]

1 A separate floating-point environment shall be maintained for each thread. Each function accesses the environment corresponding to its calling thread.

26.11 Complex numbers [complex.numbers]

1

The header `<complex>` defines a class template, and numerous functions for representing and manipulating complex numbers.

1

The effect of instantiating the template `complex` for any type other than `float`, `double`, or `long double` is unspecified. The specializations `complex<float>`, `complex<double>`, and `complex<long double>` are literal types (3.2955).

1

If the result of a function is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

1

If `z` is an lvalue expression of type *cv* `std::complex<T>` then:

— the expression `reinterpret_cast<cv T(&)[2]>(z)` shall be well-formed,

— `reinterpret_cast<cv T(&)[2]>(z)[0]` shall designate the real part of `z`, and

— `reinterpret_cast<cv T(&)[2]>(z)[1]` shall designate the imaginary part of `z`.

Moreover, if `a` is an expression of type `cv std::complex<T>*` and the expression `a[i]` is well-defined for an integer expression `i`, then:

— `reinterpret_cast<cv T*>(a)[2*i]` shall designate the real part of `a[i]`, and

— `reinterpret_cast<cv T*>(a)[2*i + 1]` shall designate the imaginary part of `a[i]`.

26.33.1 Header <complex> synopsis [complex.syn]

```
namespace std {
  template<class T> class complex;
  template<> class complex<float>;
  template<> class complex<double>;
  template<> class complex<long double>;

  // 26.34.1, operators:
  template<class T>
    complex<T> operator+(const complex<T>&, const complex<T>&);
  template<class T> complex<T> operator+(const complex<T>&, const T&);
  template<class T> complex<T> operator+(const T&, const complex<T>&);

  template<class T> complex<T> operator-(
    const complex<T>&, const complex<T>&);
  template<class T> complex<T> operator-(const complex<T>&, const T&);
  template<class T> complex<T> operator-(const T&, const complex<T>&);

  template<class T> complex<T> operator*(
    const complex<T>&, const complex<T>&);
  template<class T> complex<T> operator*(const complex<T>&, const T&);
  template<class T> complex<T> operator*(const T&, const complex<T>&);

  template<class T> complex<T> operator/(
    const complex<T>&, const complex<T>&);
  template<class T> complex<T> operator/(const complex<T>&, const T&);
  template<class T> complex<T> operator/(const T&, const complex<T>&);

  template<class T> complex<T> operator+(const complex<T>&);
  template<class T> complex<T> operator-(const complex<T>&);

  template<class T> constexpr bool operator==(
    const complex<T>&, const complex<T>&);
  template<class T> constexpr bool operator==(const complex<T>&, const T&);
  template<class T> constexpr bool operator==(const T&, const complex<T>&);

  template<class T> constexpr bool operator!=(const complex<T>&, const complex<T>&);
  template<class T> constexpr bool operator!=(const complex<T>&, const T&);
  template<class T> constexpr bool operator!=(const T&, const complex<T>&);

  template<class T, class charT, class traits>
  basic_istream<charT, traits>&
  operator>>(basic_istream<charT, traits>&, complex<T>&);

  template<class T, class charT, class traits>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>&, const complex<T>&);

  // 26.34.2, values:
  template<class T> constexpr T real(const complex<T>&);
  template<class T> constexpr T imag(const complex<T>&);

  template<class T> T abs(const complex<T>&);
  template<class T> T arg(const complex<T>&);
  template<class T> T norm(const complex<T>&);
```

```
  template<class T> complex<T> conj(const complex<T>&);
  template <class T> complex<T> proj(const complex<T>&);
  template<class T> complex<T> polar(const T&, const T& = 0);

  // 26.35.1, transcendentals:
  template<class T> complex<T> acos(const complex<T>&);
  template<class T> complex<T> asin(const complex<T>&);
  template<class T> complex<T> atan(const complex<T>&);

  template<class T> complex<T> acosh(const complex<T>&);
  template<class T> complex<T> asinh(const complex<T>&);
  template<class T> complex<T> atanh(const complex<T>&);

  template<class T> complex<T> cos  (const complex<T>&);
  template<class T> complex<T> cosh (const complex<T>&);
  template<class T> complex<T> exp  (const complex<T>&);
  template<class T> complex<T> log  (const complex<T>&);
  template<class T> complex<T> log10(const complex<T>&);

  template<class T> complex<T> pow(const complex<T>&, const T&);
  template<class T> complex<T> pow(const complex<T>&, const complex<T>&);
  template<class T> complex<T> pow(const T&, const complex<T>&);

  template<class T> complex<T> sin  (const complex<T>&);
  template<class T> complex<T> sinh (const complex<T>&);
  template<class T> complex<T> sqrt (const complex<T>&);
  template<class T> complex<T> tan  (const complex<T>&);
  template<class T> complex<T> tanh (const complex<T>&);

  // 26.43.1, complex literals:
  inline namespace literals {
    inline namespace complex_literals {
      constexpr complex<long double> operator""il(long double);
      constexpr complex<long double> operator""il(unsigned long long);
      constexpr complex<double> operator""i(long double);
      constexpr complex<double> operator""i(unsigned long long);
      constexpr complex<float> operator""if(long double);
      constexpr complex<float> operator""if(unsigned long long);
    }
  }
}
```

26.33.2 Class template `complex` [complex]

```
namespace std {
  template<class T>
  class complex {
  public:
    typedef T value_type;

    constexpr complex(const T& re = T(), const T& im = T());
    constexpr complex(const complex&);
    template<class X> constexpr complex(const complex<X>&);

    constexpr T real() const;
```

```
    void real(T);
    constexpr T imag() const;
    void imag(T);

    complex<T>& operator= (const T&);
    complex<T>& operator+=(const T&);
    complex<T>& operator-=(const T&);
    complex<T>& operator*=(const T&);
    complex<T>& operator/=(const T&);

    complex& operator=(const complex&);
    template<class X> complex<T>& operator= (const complex<X>&);
    template<class X> complex<T>& operator+=(const complex<X>&);
    template<class X> complex<T>& operator-=(const complex<X>&);
    template<class X> complex<T>& operator*=(const complex<X>&);
    template<class X> complex<T>& operator/=(const complex<X>&);
  };
}
```

1 The class `complex` describes an object that can store the Cartesian components, `real()` and `imag()`, of a complex number.

26.33.3 `complex` specializations [complex.special]

```
namespace std {
  template<> class complex<float> {
  public:
    typedef float value_type;

    constexpr complex(float re = 0.0f, float im = 0.0f);
    constexpr explicit complex(const complex<double>&);
    constexpr explicit complex(const complex<long double>&);

    constexpr float real() const;
    void real(float);
    constexpr float imag() const;
    void imag(float);

    complex<float>& operator= (float);
    complex<float>& operator+=(float);
    complex<float>& operator-=(float);
    complex<float>& operator*=(float);
    complex<float>& operator/=(float);

    complex<float>& operator=(const complex<float>&);
    template<class X> complex<float>& operator= (const complex<X>&);
    template<class X> complex<float>& operator+=(const complex<X>&);
    template<class X> complex<float>& operator-=(const complex<X>&);
    template<class X> complex<float>& operator*=(const complex<X>&);
    template<class X> complex<float>& operator/=(const complex<X>&);
  };

  template<> class complex<double> {
  public:
    typedef double value_type;
```

```
    constexpr complex(double re = 0.0, double im = 0.0);
    constexpr complex(const complex<float>&);
    constexpr explicit complex(const complex<long double>&);

    constexpr double real() const;
    void real(double);
    constexpr double imag() const;
    void imag(double);

    complex<double>& operator= (double);
    complex<double>& operator+=(double);
    complex<double>& operator-=(double);
    complex<double>& operator*=(double);
    complex<double>& operator/=(double);

    complex<double>& operator=(const complex<double>&);
    template<class X> complex<double>& operator= (const complex<X>&);
    template<class X> complex<double>& operator+=(const complex<X>&);
    template<class X> complex<double>& operator-=(const complex<X>&);
    template<class X> complex<double>& operator*=(const complex<X>&);
    template<class X> complex<double>& operator/=(const complex<X>&);
  };

  template<> class complex<long double> {
  public:
    typedef long double value_type;

    constexpr complex(long double re = 0.0L, long double im = 0.0L);
    constexpr complex(const complex<float>&);
    constexpr complex(const complex<double>&);

    constexpr long double real() const;
    void real(long double);
    constexpr long double imag() const;
    void imag(long double);

    complex<long double>& operator=(const complex<long double>&);
    complex<long double>& operator= (long double);
    complex<long double>& operator+=(long double);
    complex<long double>& operator-=(long double);
    complex<long double>& operator*=(long double);
    complex<long double>& operator/=(long double);

    template<class X> complex<long double>& operator= (const complex<X>&);
    template<class X> complex<long double>& operator+=(const complex<X>&);
    template<class X> complex<long double>& operator-=(const complex<X>&);
    template<class X> complex<long double>& operator*=(const complex<X>&);
    template<class X> complex<long double>& operator/=(const complex<X>&);
  };
}
```

26.33.4 `complex` member functions [complex.members]

`template<class T> constexpr complex(const T& re = T(), const T& im = T());`

1 *Effects:* Constructs an object of class `complex`.

2 *Postcondition:* `real() == re && imag() == im`.

`constexpr T real() const;`

Returns: The value of the real component.

`void real(T val);`

Effects: Assigns `val` to the real component.

`constexpr T imag() const;`

Returns: The value of the imaginary component.

`void imag(T val);`

Effects: Assigns `val` to the imaginary component.

26.33.5 `complex` member operators [complex.member.ops]

`complex<T>& operator+=(const T& rhs);`

1 *Effects:* Adds the scalar value `rhs` to the real part of the complex value `*this` and stores the result in the real part of `*this`, leaving the imaginary part unchanged.

2 *Returns:* `*this`.

`complex<T>& operator-=(const T& rhs);`

3 *Effects:* Subtracts the scalar value `rhs` from the real part of the complex value `*this` and stores the result in the real part of `*this`, leaving the imaginary part unchanged.

4 *Returns:* `*this`.

`complex<T>& operator*=(const T& rhs);`

5 *Effects:* Multiplies the scalar value `rhs` by the complex value `*this` and stores the result in `*this`.

6 *Returns:* `*this`.

`complex<T>& operator/=(const T& rhs);`

7 *Effects:* Divides the scalar value `rhs` into the complex value `*this` and stores the result in `*this`.

8 *Returns:* `*this`.

`template<class X> complex<T>& operator+=(const complex<X>& rhs);`

9 *Effects:* Adds the complex value `rhs` to the complex value `*this` and stores the sum in `*this`.

10 *Returns:* `*this`.

`template<class X> complex<T>& operator-=(const complex<X>& rhs);`

11 *Effects:* Subtracts the complex value `rhs` from the complex value `*this` and stores the difference in `*this`.

12 *Returns:* `*this`.

`template<class X> complex<T>& operator*=(const complex<X>& rhs);`

13 *Effects:* Multiplies the complex value `rhs` by the complex value `*this` and stores the product in `*this`.

Returns: `*this`.

```
template<class X> complex<T>& operator/=(const complex<X>& rhs);
```

14

Effects: Divides the complex value `rhs` into the complex value `*this` and stores the quotient in `*this`.

1 *Returns:* `*this`.

26.34.1 `complex` non-member operations [complex.ops]

```
template<class T> complex<T> operator+(const complex<T>& lhs);
```

1 *Remarks:* unary operator.

2 *Returns:* `complex<T>(lhs)`.

```
  template<class T>
    complex<T> operator+(const complex<T>& lhs, const complex<T>& rhs);
  template<class T> complex<T> operator+(const complex<T>& lhs, const T& rhs);
  template<class T> complex<T> operator+(const T& lhs, const complex<T>& rhs);
```

3 *Returns:* `complex<T>(lhs) += rhs`.

```
template<class T> complex<T> operator-(const complex<T>& lhs);
```

4 *Remarks:* unary operator.

5 *Returns:* `complex<T>(-lhs.real(),-lhs.imag())`.

```
template<class T>
  complex<T> operator-(const complex<T>& lhs, const complex<T>& rhs);
template<class T> complex<T> operator-(const complex<T>& lhs, const T& rhs);
template<class T> complex<T> operator-(const T& lhs, const complex<T>& rhs);
```

6 *Returns:* `complex<T>(lhs) -= rhs`.

```
template<class T>
  complex<T> operator*(const complex<T>& lhs, const complex<T>& rhs);
template<class T> complex<T> operator*(const complex<T>& lhs, const T& rhs);
template<class T> complex<T> operator*(const T& lhs, const complex<T>& rhs);
```

7 *Returns:* `complex<T>(lhs) *= rhs`.

```
template<class T>
  complex<T> operator/(const complex<T>& lhs, const complex<T>& rhs);
template<class T> complex<T> operator/(const complex<T>& lhs, const T& rhs);
template<class T> complex<T> operator/(const T& lhs, const complex<T>& rhs);
```

8 *Returns:* `complex<T>(lhs) /= rhs`.

```
template<class T>
  constexpr bool operator==(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr bool operator==(const complex<T>& lhs, const T& rhs);
template<class T> constexpr bool operator==(const T& lhs, const complex<T>& rhs);
```

9 *Returns:* `lhs.real() == rhs.real() && lhs.imag() == rhs.imag()`.

10 *Remarks:* The imaginary part is assumed to be `T()`, or 0.0, for the `T` arguments.

```
template<class T>
  constexpr bool operator!=(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr bool operator!=(const complex<T>& lhs, const T& rhs);
template<class T> constexpr bool operator!=(const T& lhs, const complex<T>& rhs);
```

11 *Returns:* `rhs.real() != lhs.real() || rhs.imag() != lhs.imag()`.

```
template<class T, class charT, class traits>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, complex<T>& x);
```

12 *Effects:* Extracts a complex number `x` of the form: `u`, `(u)`, or `(u,v)`, where `u` is the real part and `v` is the imaginary part (27.128.0.1).

13 *Requires:* The input values shall be convertible to `T`.

If bad input is encountered, calls `is.setstate(ios_base::failbit)` (which may throw `ios::failure` (27.84.0.1)).

14 *Returns:* `is`.

15 *Remarks:* This extraction is performed as a series of simpler extractions. Therefore, the skipping of whitespace is specified to be the same for each of the simpler extractions.

```
template<class T, class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& o, const complex<T>& x);
```

16 *Effects:* inserts the complex number `x` onto the stream `o` as if it were implemented as follows:

```
template<class T, class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& o, const complex<T>& x) {
  basic_ostringstream<charT, traits> s;
  s.flags(o.flags());
  s.imbue(o.getloc());
  s.precision(o.precision());
  s << '(' << x.real() << "," << x.imag() << ')';
  return o << s.str();
}
```

17 *Note:* In a locale in which comma is used as a decimal point character, the use of comma as a field separator can be ambiguous. Inserting `std::showpoint` into the output stream forces all outputs to show an explicit decimal point character; as a result, all inserted sequences of complex numbers can be extracted unambiguously.

26.34.2 `complex` value operations [complex.value.ops]

```
template<class T> constexpr T real(const complex<T>& x);
```

1 *Returns:* `x.real()`.

```
template<class T> constexpr T imag(const complex<T>& x);
```

2 *Returns:* `x.imag()`.

```
template<class T> T abs(const complex<T>& x);
```

3 *Returns:* The magnitude of `x`.

```
template<class T> T arg(const complex<T>& x);
```

4 *Returns:* The phase angle of `x`, or `atan2(imag(x), real(x))`.

```
template<class T> T norm(const complex<T>& x);
```

1 *Returns:* The squared magnitude of `x`.

```
template<class T> complex<T> conj(const complex<T>& x);
```

2 *Returns:* The complex conjugate of `x`.

```
template<class T> complex<T> proj(const complex<T>& x);
```

3 *Returns:* The projection of `x` onto the Riemann sphere.

4 *Remarks:* Behaves the same as the C function `cproj`, defined in 7.3.9.4.

```
template<class T> complex<T> polar(const T& rho, const T& theta = 0);
```

5 *Returns:* The `complex` value corresponding to a complex number whose magnitude is `rho` and whose phase angle is `theta`.

26.35.1 `complex` transcendentals [complex.transcendentals]

```
template<class T> complex<T> acos(const complex<T>& x);
```

1 *Returns:* The complex arc cosine of `x`.

2 *Remarks:* Behaves the same as C function `cacos`, defined in 7.3.5.1.

```
template<class T> complex<T> asin(const complex<T>& x);
```

3 *Returns:* The complex arc sine of `x`.

4 *Remarks:* Behaves the same as C function `casin`, defined in 7.3.5.2.

```
template<class T> complex<T> atan(const complex<T>& x);
```

5 *Returns:* The complex arc tangent of `x`.

6 *Remarks:* Behaves the same as C function `catan`, defined in 7.3.5.3.

```
template<class T> complex<T> acosh(const complex<T>& x);
```

7 *Returns:* The complex arc hyperbolic cosine of `x`.

8 *Remarks:* Behaves the same as C function `cacosh`, defined in 7.3.6.1.

```
template<class T> complex<T> asinh(const complex<T>& x);
```

9 *Returns:* The complex arc hyperbolic sine of `x`.

10 *Remarks:* Behaves the same as C function `casinh`, defined in 7.3.6.2.

```
template<class T> complex<T> atanh(const complex<T>& x);
```

11 *Returns:* The complex arc hyperbolic tangent of `x`.

12 *Remarks:* Behaves the same as C function `catanh`, defined in 7.3.6.3.

```
template<class T> complex<T> cos(const complex<T>& x);
```

13 *Returns:* The complex cosine of `x`.

```
template<class T> complex<T> cosh(const complex<T>& x);
```

14 *Returns:* The complex hyperbolic cosine of `x`.

```
template<class T> complex<T> exp(const complex<T>& x);
```

15 *Returns:* The complex base e exponential of `x`.

```
template<class T> complex<T> log(const complex<T>& x);
```

16 *Remarks:* the branch cuts are along the negative real axis.

17 *Returns:* The complex natural (base e) logarithm of `x`, in the range of a strip mathematically unbounded along the real axis and in the interval `[-i times pi,i times pi]` along the imaginary axis. When `x` is a negative real number, `imag(log(x))` is pi.

```
template<class T> complex<T> log10(const complex<T>& x);
```

18 *Remarks:* the branch cuts are along the negative real axis.

19 *Returns:* The complex common (base 10) logarithm of `x`, defined as `log(x)/log(10)`.

```
template<class T>
  complex<T> pow(const complex<T>& x, const complex<T>& y);
template<class T> complex<T> pow  (const complex<T>& x, const T& y);
template<class T> complex<T> pow  (const T& x, const complex<T>& y);
```

20 *Remarks:* the branch cuts are along the negative real axis.

21 *Returns:* The complex power of base `x` raised to the `y`-th power, defined as `exp(y*log(x))`. The value returned for `pow(0,0)` is implementation-defined.

```
template<class T> complex<T> sin  (const complex<T>& x);
```

22 *Returns:* The complex sine of `x`.

```
template<class T> complex<T> sinh (const complex<T>& x);
```

23 *Returns:* The complex hyperbolic sine of `x`.

```
template<class T> complex<T> sqrt (const complex<T>& x);
```

24 *Remarks:* the branch cuts are along the negative real axis.

25

Returns: The complex square root of `x`, in the range of the right half-plane. If the argument is a negative real number, the value returned lies on the positive imaginary axis.

```
template<class T> complex<T> tan  (const complex<T>& x);
```

1 *Returns:* The complex tangent of `x`.

```
template<class T> complex<T> tanh (const complex<T>& x);
```

2 *Returns:* The complex hyperbolic tangent of `x`.

26.36.1 Additional overloads [cmplx.over]

1

The following function templates shall have additional overloads:

```
arg                 norm
conj                proj
imag                real
```

1

The additional overloads shall be sufficient to ensure:

1. If the argument has type `long double`, then it is effectively cast to `complex<long double>`.
2. Otherwise, if the argument has type `double` or an integer type, then it is effectively cast to `complex<double>`.
3. Otherwise, if the argument has type `float`, then it is effectively cast to `complex<float>`.

1

Function template `pow` shall have additional overloads sufficient to ensure, for a call with at least one argument of type `complex<T>`:

1. If either argument has type `complex<long double>` or type `long double`, then both arguments are effectively cast to `complex<long double>`.
2. Otherwise, if either argument has type `complex<double>`, `double`, or an integer type, then both arguments are effectively cast to `complex<double>`.
3. Otherwise, if either argument has type `complex<float>` or `float`, then both arguments are effectively cast to `complex<float>`.

26.43.1 Suffixes for complex number literals [complex.literals]

1 This section describes literal suffixes for constructing complex number literals. The suffixes `i`, `il`, and `if` create complex numbers of the types `complex<double>`, `complex<long double>`, and `complex<float>` respectively, with their imaginary part denoted by the given literal number and the real part being zero.

```
constexpr complex<long double> operator""il(long double d);
constexpr complex<long double> operator""il(unsigned long long d);
```

2 *Returns:* `complex<long double>{0.0L, static_cast<long double>(d)}`.

```
constexpr complex<double> operator""i(long double d);
constexpr complex<double> operator""i(unsigned long long d);
```

3 *Returns:* `complex<double>{0.0, static_cast<double>(d)}`.

```
constexpr complex<float> operator""if(long double d);
constexpr complex<float> operator""if(unsigned long long d);
```

4 *Returns:* `complex<float>{0.0f, static_cast<float>(d)}`.

26.43.2 Header `<ccomplex>` [ccmplx]

1

The header behaves as if it simply includes the header `<complex>`.

26.45 Random number generation [rand]

1 This subclause defines a facility for generating (pseudo-)random numbers.

2

In addition to a few utilities, four categories of entities are described: *uniform random number generators*, *random number engines*, *random number engine adaptors*, and *random number distributions*. These categorizations are applicable to types that satisfy the corresponding requirements, to objects instantiated from such types, and to templates producing such types when instantiated. [*Note:* These entities are specified in

such a way as to permit the binding of any uniform random number generator object `e` as the argument to any random number distribution object `d`, thus producing a zero-argument function object such as given by `bind(d,e)`. — *end note*]

1 Each of the entities specified via this subclause has an associated arithmetic type (3.3151.1) identified as `result_type`. With `T` as the `result_type` thus associated with such an entity, that entity is characterized:

a) as *boolean* or equivalently as *boolean-valued*, if `T` is `bool`;

b) otherwise as *integral* or equivalently as *integer-valued*, if `numeric_limits<T>::is_integer` is `true`;

c) otherwise as *floating* or equivalently as *real-valued*.

If integer-valued, an entity may optionally be further characterized as *signed* or *unsigned*, according to `numeric_limits<T>::is_signed`.

2 Unless otherwise specified, all descriptions of calculations in this subclause use mathematical real numbers.

3 Throughout this subclause, the operators bitand, bitor, and xor denote the respective conventional bitwise operations. Further:

a) the operator rshift denotes a bitwise right shift with zero-valued bits appearing in the high bits of the result, and

b) the operator lshift_w denotes a bitwise left shift with zero-valued bits appearing in the low bits of the result, and whose result is always taken modulo 2^w.

26.46.1 Requirements [rand.req]

26.46.1.1 General requirements [rand.req.genl]

1

Throughout this subclause 26.45, the effect of instantiating a template:

a) that has a template type parameter named `Sseq` is undefined unless the corresponding template argument is cv-unqualified and satisfies the requirements of seed sequence (26.70.0.1).

b) that has a template type parameter named `URNG` is undefined unless the corresponding template argument is cv-unqualified and satisfies the requirements of uniform random number generator (26.75.0.1).

c) that has a template type parameter named `Engine` is undefined unless the corresponding template argument is cv-unqualified and satisfies the requirements of random number engine (26.81.0.1).

d) that has a template type parameter named `RealType` is undefined unless the corresponding template argument is cv-unqualified and is one of `float`, `double`, or `long double`.

e) that has a template type parameter named `IntType` is undefined unless the corresponding template argument is cv-unqualified and is one of `short`, `int`, `long`, `long long`, `unsigned short`, `unsigned int`, `unsigned long`, or `unsigned long long`.

f) that has a template type parameter named `UIntType` is undefined unless the corresponding template argument is cv-unqualified and is one of `unsigned short`, `unsigned int`, `unsigned long`, or `unsigned long long`.

1 Throughout this subclause 26.45, phrases of the form "`x` is an iterator of a specific kind" shall be interpreted as equivalent to the more formal requirement that "`x` is a value of a type satisfying the requirements of the specified iterator type."

2 Throughout this subclause 26.45, any constructor that can be called with a single argument and that satisfies a requirement specified in this subclause shall be declared `explicit`.

26.70.0.1 Seed sequence requirements [rand.req.seedseq]

1

A *seed sequence* is an object that consumes a sequence of integer-valued data and produces a requested number of unsigned integer values i, $0 \leq i < 2^{32}$, based on the consumed data. [*Note:* Such an object provides a mechanism to avoid replication of streams of random variates. This can be useful, for example, in applications requiring large numbers of random number engines. — *end note*]

1

A class `S` satisfies the requirements of a seed sequence if the expressions shown in Table 115 are valid and have the indicated semantics, and if `S` also satisfies all other requirements of this section 26.70.0.1. In that Table and throughout this section:

a) `T` is the type named by `S`'s associated `result_type`;

b) `q` is a value of `S` and `r` is a possibly const value of `S`;

c) `ib` and `ie` are input iterators with an unsigned integer `value_type` of at least 32 bits;

d) `rb` and `re` are mutable random access iterators with an unsigned integer `value_type` of at least 32 bits;

e) `ob` is an output iterator; and

f) `il` is a value of `initializer_list<T>`.

Table 115 — Seed sequence requirements

Expression	Return type	Pre/post-condition	Complexity
`S::result_type`	`T`	`T` is an unsigned integer type (3.3151.1) of at least 32 bits.	compile-time
`S()`		Creates a seed sequence with the same initial state as all other default-constructed seed sequences of type `S`.	constant
`S(ib,ie)`		Creates a seed sequence having internal state that depends on some or all of the bits of the supplied sequence $[\texttt{ib}, \texttt{ie})$.	$\mathcal{O}(\texttt{ie} - \texttt{ib})$
`S(il)`		Same as `S(il.begin(), il.end())`.	same as `S(il.begin(), il.end())`
`q.generate(rb,re)`	`void`	Does nothing if `rb == re`. Otherwise, fills the supplied sequence $[\texttt{rb}, \texttt{re})$ with 32-bit quantities that depend on the sequence supplied to the constructor and possibly also depend on the history of `generate`'s previous invocations.	$\mathcal{O}(\texttt{re} - \texttt{rb})$

Table 115 — Seed sequence requirements (continued)

Expression	Return type	Pre/post-condition	Complexity
`r.size()`	`size_t`	The number of 32-bit units that would be copied by a call to `r.param`.	constant
`r.param(ob)`	`void`	Copies to the given destination a sequence of 32-bit units that can be provided to the constructor of a second object of type `S`, and that would reproduce in that second object a state indistinguishable from the state of the first object.	$\mathcal{O}$(`r.size()`)

26.75.0.1 Uniform random number generator requirements [rand.req.urng]

1

A *uniform random number generator* `g` of type `G` is a function object returning unsigned integer values such that each value in the range of possible results has (ideally) equal probability of being returned. [*Note:* The degree to which `g`'s results approximate the ideal is often determined statistically. — *end note*]

1

A class `G` satisfies the requirements of a *uniform random number generator* if the expressions shown in Table 116 are valid and have the indicated semantics, and if `G` also satisfies all other requirements of this section 26.75.0.1. In that Table and throughout this section:

a) `T` is the type named by `G`'s associated `result_type`, and

b) `g` is a value of `G`.

Table 116 — Uniform random number generator requirements

Expression	Return type	Pre/post-condition	Complexity
`G::result_type`	`T`	`T` is an unsigned integer type (3.3151.1).	compile-time
`g()`	`T`	Returns a value in the closed interval [`G::min()`, `G::max()`].	amortized constant
`G::min()`	`T`	Denotes the least value potentially returned by `operator()`.	compile-time
`G::max()`	`T`	Denotes the greatest value potentially returned by `operator()`.	compile-time

1

The following relation shall hold: `G::min() < G::max()`.

26.81.0.1 Random number engine requirements [rand.req.eng]

1 A *random number engine* (commonly shortened to *engine*) `e` of type `E` is a uniform random number generator that additionally meets the requirements (*e.g.*, for seeding and for input/output) specified in this section.

2 At any given time, `e` has a state $\mathtt{e}_i$ for some integer $i \geq 0$. Upon construction, `e` has an initial state $\mathtt{e}_0$. An engine's state may be established via a constructor, a `seed` function, assignment, or a suitable `operator>>`.

3 `E`'s specification shall define:

a) the size of `E`'s state in multiples of the size of `result_type`, given as an integral constant expression;

b) the *transition algorithm* TA by which `e`'s state $\mathtt{e}_i$ is advanced to its *successor state* $\mathtt{e}_{i+1}$; and

c) the *generation algorithm* GA by which an engine's state is mapped to a value of type `result_type`.

4

A class `E` that satisfies the requirements of a uniform random number generator (26.75.0.1) also satisfies the requirements of a *random number engine* if the expressions shown in Table 117 are valid and have the indicated semantics, and if `E` also satisfies all other requirements of this section 26.81.0.1. In that Table and throughout this section:

a) `T` is the type named by `E`'s associated `result_type`;

b) `e` is a value of `E`, `v` is an lvalue of `E`, `x` and `y` are (possibly `const`) values of `E`;

c) `s` is a value of `T`;

d) `q` is an lvalue satisfying the requirements of a seed sequence (26.70.0.1);

e) `z` is a value of type `unsigned long long`;

f) `os` is an lvalue of the type of some class template specialization `basic_ostream<charT, traits>`; and

g) `is` is an lvalue of the type of some class template specialization `basic_istream<charT, traits>`;

where `charT` and `traits` are constrained according to Clause 21 and Clause 27.

Table 117 — Random number engine requirements

Expression	Return type	Pre/post-condition	Complexity
`E()`		Creates an engine with the same initial state as all other default-constructed engines of type `E`.	$\mathcal{O}$(size of state)
`E(x)`		Creates an engine that compares equal to `x`.	$\mathcal{O}$(size of state)
`E(s)`		Creates an engine with initial state determined by `s`.	$\mathcal{O}$(size of state)

Expression	Return type	Pre/post-condition	Complexity
`E(q)`[273]		Creates an engine with an initial state that depends on a sequence produced by one call to `q.generate`.	same as complexity of `q.generate` called on a sequence whose length is size of state
`e.seed()`	`void`	post: `e == E()`.	same as `E()`
`e.seed(s)`	`void`	post: `e == E(s)`.	same as `E(s)`
`e.seed(q)`	`void`	post: `e == E(q)`.	same as `E(q)`
`e()`	`T`	Advances `e`'s state $\mathtt{e}_i$ to $\mathtt{e}_{i+1}$ = $\mathsf{TA}(\mathtt{e}_i)$ and returns $\mathsf{GA}(\mathtt{e}_i)$.	per Table 116
`e.discard(z)` [274]	`void`	Advances `e`'s state $\mathtt{e}_i$ to $\mathtt{e}_{i+\mathtt{z}}$ by any means equivalent to `z` consecutive calls `e()`.	no worse than the complexity of `z` consecutive calls `e()`
`x == y`	`bool`	This operator is an equivalence relation. With S_x and S_y as the infinite sequences of values that would be generated by repeated future calls to `x()` and `y()`, respectively, returns `true` if $S_x = S_y$; else returns `false`.	$\mathcal{O}$(size of state)
`x != y`	`bool`	`!(x == y)`.	$\mathcal{O}$(size of state)
`os << x`	reference to the type of `os`	With `os.`*fmtflags* set to `ios_base::dec|ios_base::left` and the fill character set to the space character, writes to `os` the textual representation of `x`'s current state. In the output, adjacent numbers are separated by one or more space characters. post: The `os.`*fmtflags* and fill character are unchanged.	$\mathcal{O}$(size of state)

273) This constructor (as well as the subsequent corresponding `seed()` function) may be particularly useful to applications requiring a large number of independent random sequences.

274) This operation is common in user code, and can often be implemented in an engine-specific manner so as to provide significant performance improvements over an equivalent naive loop that makes `z` consecutive calls `e()`.

Expression	Return type	Pre/post-condition	Complexity
`is >> v`	reference to the type of `is`	With `is.fmtflags` set to `ios_base::dec`, sets `v`'s state as determined by reading its textual representation from `is`. If bad input is encountered, ensures that `v`'s state is unchanged by the operation and calls `is.setstate(ios::failbit)` (which may throw `ios::failure` [27.84.0.1]). If a textual representation written via `os << x` was subsequently read via `is >> v`, then `x == v` provided that there have been no intervening invocations of `x` or of `v`. pre: `is` provides a textual representation that was previously written using an output stream whose imbued locale was the same as that of `is`, and whose type's template specialization arguments `charT` and `traits` were respectively the same as those of `is`. post: The `is.`*fmtflags* are unchanged.	$\mathcal{O}$(size of state)

1 `E` shall meet the requirements of `CopyConstructible` (Table 21) and `CopyAssignable` (Table 23) types. These operations shall each be of complexity no worse than $\mathcal{O}$(size of state).

26.88.0.1 Random number engine adaptor requirements [rand.req.adapt]

1 A *random number engine adaptor* (commonly shortened to *adaptor*) `a` of type `A` is a random number engine that takes values produced by some other random number engine, and applies an algorithm to those values in order to deliver a sequence of values with different randomness properties. An engine `b` of type `B` adapted in this way is termed a *base engine* in this context. The expression `a.base()` shall be valid and shall return a const reference to `a`'s base engine.

2 The requirements of a random number engine type shall be interpreted as follows with respect to a random number engine adaptor type.

```
A::A();
```

3 *Effects:* The base engine is initialized as if by its default constructor.

```
bool operator==(const A& a1, const A& a2);
```

4 *Returns:* `true` if `a1`'s base engine is equal to `a2`'s base engine. Otherwise returns `false`.

```
A::A(result_type s);
```

5 *Effects:* The base engine is initialized with `s`.

```
template<class Sseq> void A::A(Sseq& q);
```

6 *Effects:* The base engine is initialized with `q`.

```
void seed();
```

7 *Effects:* With `b` as the base engine, invokes `b.seed()`.

```
void seed(result_type s);
```

8 *Effects:* With `b` as the base engine, invokes `b.seed(s)`.

```
template<class Sseq> void seed(Sseq& q);
```

9 *Effects:* With `b` as the base engine, invokes `b.seed(q)`.

10 `A` shall also satisfy the following additional requirements:

a) The complexity of each function shall not exceed the complexity of the corresponding function applied to the base engine.

b) The state of `A` shall include the state of its base engine. The size of `A`'s state shall be no less than the size of the base engine.

c) Copying `A`'s state (*e.g.*, during copy construction or copy assignment) shall include copying the state of the base engine of `A`.

d) The textual representation of `A` shall include the textual representation of its base engine.

26.88.0.2 Random number distribution requirements [rand.req.dist]

1 A *random number distribution* (commonly shortened to *distribution*) `d` of type `D` is a function object returning values that are distributed according to an associated mathematical *probability density function* $p(z)$ or according to an associated *discrete probability function* $P(z_i)$. A distribution's specification identifies its associated probability function $p(z)$ or $P(z_i)$.

2 An associated probability function is typically expressed using certain externally-supplied quantities known as the *parameters of the distribution*. Such distribution parameters are identified in this context by writing, for example, $p(z \mid a, b)$ or $P(z_i \mid a, b)$, to name specific parameters, or by writing, for example, $p(z \mid \{\mathtt{p}\})$ or $P(z_i \mid \{\mathtt{p}\})$, to denote a distribution's parameters `p` taken as a whole.

3

A class `D` satisfies the requirements of a *random number distribution* if the expressions shown in Table 118 are valid and have the indicated semantics, and if `D` and its associated types also satisfy all other requirements of this section 26.88.0.2. In that Table and throughout this section,

a) `T` is the type named by `D`'s associated `result_type`;

b) `P` is the type named by `D`'s associated `param_type`;

c) `d` is a value of `D`, and `x` and `y` are (possibly `const`) values of `D`;

d) `glb` and `lub` are values of `T` respectively corresponding to the greatest lower bound and the least upper bound on the values potentially returned by `d`'s `operator()`, as determined by the current values of `d`'s parameters;

e) `p` is a (possibly `const`) value of `P`;

f) `g`, `g1`, and `g2` are lvalues of a type satisfying the requirements of a uniform random number generator [26.75.0.1];

g) `os` is an lvalue of the type of some class template specialization `basic_ostream<charT, traits>`; and

h) `is` is an lvalue of the type of some class template specialization `basic_istream<charT, traits>`;

where `charT` and `traits` are constrained according to Clauses 21 and 27.

Table 118 — Random number distribution requirements

Expression	Return type	Pre/post-condition	Complexity
`D::result_type`	`T`	`T` is an arithmetic type (3.3151.1).	compile-time
`D::param_type`	`P`		compile-time
`D()`		Creates a distribution whose behavior is indistinguishable from that of any other newly default-constructed distribution of type `D`.	constant
`D(p)`		Creates a distribution whose behavior is indistinguishable from that of a distribution newly constructed directly from the values used to construct `p`.	same as `p`'s construction
`d.reset()`	`void`	Subsequent uses of `d` do not depend on values produced by any engine prior to invoking `reset`.	constant
`x.param()`	`P`	Returns a value `p` such that `D(p).param() == p`.	no worse than the complexity of `D(p)`
`d.param(p)`	`void`	post: `d.param() == p`.	no worse than the complexity of `D(p)`
`d(g)`	`T`	With `p` = `d.param()`, the sequence of numbers returned by successive invocations with the same object `g` is randomly distributed according to the associated $p(z \mid \{\mathtt{p}\})$ or $P(z_i \mid \{\mathtt{p}\})$ function.	amortized constant number of invocations of `g`
`d(g,p)`	`T`	The sequence of numbers returned by successive invocations with the same objects `g` and `p` is randomly distributed according to the associated $p(z \mid \{\mathtt{p}\})$ or $P(z_i \mid \{\mathtt{p}\})$ function.	amortized constant number of invocations of `g`
`x.min()`	`T`	Returns `glb`.	constant
`x.max()`	`T`	Returns `lub`.	constant

Expression	Return type	Pre/post-condition	Complexity
`x == y`	`bool`	This operator is an equivalence relation. Returns `true` if `x.param() == y.param()` and $S_1 = S_2$, where S_1 and S_2 are the infinite sequences of values that would be generated, respectively, by repeated future calls to `x(g1)` and `y(g2)` whenever `g1 == g2`. Otherwise returns `false`.	constant
`x != y`	`bool`	`!(x == y)`.	same as `x == y`.
`os << x`	reference to the type of `os`	Writes to `os` a textual representation for the parameters and the additional internal data of `x`. post: The `os.`*fmtflags* and fill character are unchanged.	
`is >> d`	reference to the type of `is`	Restores from `is` the parameters and additional internal data of the lvalue `d`. If bad input is encountered, ensures that `d` is unchanged by the operation and calls `is.setstate(ios::failbit)` (which may throw `ios::failure` [27.84.0.1]). pre: `is` provides a textual representation that was previously written using an `os` whose imbued locale and whose type's template specialization arguments `charT` and `traits` were the same as those of `is`. post: The `is.`*fmtflags* are unchanged.	

1 `D` shall satisfy the requirements of `CopyConstructible` (Table 21) and `CopyAssignable` (Table 23) types.

2 The sequence of numbers produced by repeated invocations of `d(g)` shall be independent of any invocation of `os << d` or of any `const` member function of `D` between any of the invocations `d(g)`.

3 If a textual representation is written using `os << x` and that representation is restored into the same or a different object `y` of the same type using `is >> y`, repeated invocations of `y(g)` shall produce the same sequence of numbers as would repeated invocations of `x(g)`.

4

It is unspecified whether `D::param_type` is declared as a (nested) `class` or via a `typedef`. In this subclause 26.45, declarations of `D::param_type` are in the form of `typedef`s for convenience of exposition only.

1 `P` shall satisfy the requirements of `CopyConstructible` (Table 21), `CopyAssignable` (Table 23), and `EqualityComparable`

(Table 17) types.

2

For each of the constructors of `D` taking arguments corresponding to parameters of the distribution, `P` shall have a corresponding constructor subject to the same requirements and taking arguments identical in number, type, and default values. Moreover, for each of the member functions of `D` that return values corresponding to parameters of the distribution, `P` shall have a corresponding member function with the identical name, type, and semantics.

1 `P` shall have a declaration of the form

```
typedef  D  distribution_type;
```

26.97.2 Random number engine class templates [rand.eng]

1 Each type instantiated from a class template specified in this section 26.97.2 satisfies the requirements of a random number engine (26.81.0.1) type.

2 Except where specified otherwise, the complexity of each function specified in this section 26.97.2 is constant.

3 Except where specified otherwise, no function described in this section 26.97.2 throws an exception.

4 Descriptions are provided in this section 26.97.2 only for engine operations that are not described in 26.81.0.1 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

5 Each template specified in this section 26.97.2 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

6

For every random number engine and for every random number engine adaptor `X` defined in this subclause (26.97.2) and in sub-clause 26.101.1:

— if the constructor

```
template <class Sseq> explicit X(Sseq& q);
```

is called with a type `Sseq` that does not qualify as a seed sequence, then this constructor shall not participate in overload resolution;

— if the member function

```
template <class Sseq> void seed(Sseq& q);
```

is called with a type `Sseq` that does not qualify as a seed sequence, then this function shall not participate in overload resolution.

The extent to which an implementation determines that a type cannot be a seed sequence is unspecified, except that as a minimum a type shall not qualify as a seed sequence if it is implicitly convertible to `X::result_type`.

26.98.0.1 Class template `linear_congruential_engine` [rand.eng.lcong]

1 A `linear_congruential_engine` random number engine produces unsigned integer random numbers. The state $\mathtt{x}_i$ of a `linear_congruential_engine` object `x` is of size 1 and consists of a single integer. The transition algorithm is a modular linear function of the form $\mathsf{TA}(\mathtt{x}_i) = (a \cdot \mathtt{x}_i + c) \bmod m$; the generation algorithm is $\mathsf{GA}(\mathtt{x}_i) = \mathtt{x}_{i+1}$.

```
template<class UIntType, UIntType a, UIntType c, UIntType m>
 class linear_congruential_engine
{
public:
 // types
 typedef UIntType result_type;

 // engine characteristics
 static constexpr result_type multiplier = a;
 static constexpr result_type increment = c;
 static constexpr result_type modulus = m;
 static constexpr result_type min() { return c == 0u ? 1u: 0u; }
 static constexpr result_type max() { return m - 1u; }
 static constexpr result_type default_seed = 1u;

 // constructors and seeding functions
 explicit linear_congruential_engine(result_type s = default_seed);
 template<class Sseq> explicit linear_congruential_engine(Sseq& q);
 void seed(result_type s = default_seed);
 template<class Sseq> void seed(Sseq& q);

 // generating functions
 result_type operator()();
 void discard(unsigned long long z);
};
```

2 If the template parameter `m` is 0, the modulus m used throughout this section 26.98.0.1 is `numeric_limits<result_type>::max()` plus 1. [*Note:* m need not be representable as a value of type `result_type`. — *end note*]

3 If the template parameter `m` is not 0, the following relations shall hold: `a < m` and `c < m`.

4 The textual representation consists of the value of $\mathtt{x}_i$.

```
explicit linear_congruential_engine(result_type s = default_seed);
```

5 *Effects:* Constructs a `linear_congruential_engine` object. If $c \bmod m$ is 0 and `s` mod m is 0, sets the engine's state to 1, otherwise sets the engine's state to `s` mod m.

```
template<class Sseq> explicit linear_congruential_engine(Sseq& q);
```

1 *Effects:* Constructs a `linear_congruential_engine` object. With $k = \left\lceil \frac{\log_2 m}{32} \right\rceil$ and a an array (or equivalent) of length $k+3$, invokes `q.generate(`$a+0$`, `$a+k+3$`)` and then computes $S = \left(\sum_{j=0}^{k-1} a_{j+3} \cdot 2^{32j}\right) \bmod m$. If $c \bmod m$ is 0 and S is 0, sets the engine's state to 1, else sets the engine's state to S.

26.100.0.1 Class template `mersenne_twister_engine` [rand.eng.mers]

1

A `mersenne_twister_engine` random number engine[275] produces unsigned integer random numbers in the closed interval $[0, 2^w - 1]$. The state $\mathtt{x}_i$ of a `mersenne_twister_engine` object `x` is of size n and consists of a sequence X of n values of the type delivered by `x`; all subscripts applied to X are to be taken modulo n.

1 The transition algorithm employs a twisted generalized feedback shift register defined by shift values n and m, a twist value r, and a conditional xor-mask a. To improve the uniformity of the result, the bits of the raw shift register are additionally *tempered* (*i.e.*, scrambled) according to a bit-scrambling matrix defined by values u, d, s, b, t, c, and ℓ.

The state transition is performed as follows:

a) Concatenate the upper $w-r$ bits of X_{i-n} with the lower r bits of X_{i+1-n} to obtain an unsigned integer value Y.

b) With $\alpha = a \cdot (Y \,\mathsf{bitand}\, 1)$, set X_i to $X_{i+m-n} \,\mathsf{xor}\, (Y \,\mathsf{rshift}\, 1) \,\mathsf{xor}\, \alpha$.

The sequence X is initialized with the help of an initialization multiplier f.

2 The generation algorithm determines the unsigned integer values z_1, z_2, z_3, z_4 as follows, then delivers z_4 as its result:

a) Let $z_1 = X_i \,\mathsf{xor}\, \big((X_i \,\mathsf{rshift}\, u) \,\mathsf{bitand}\, d\big)$.

b) Let $z_2 = z_1 \,\mathsf{xor}\, \big((z_1 \,\mathsf{lshift}_w\, s) \,\mathsf{bitand}\, b\big)$.

c) Let $z_3 = z_2 \,\mathsf{xor}\, \big((z_2 \,\mathsf{lshift}_w\, t) \,\mathsf{bitand}\, c\big)$.

d) Let $z_4 = z_3 \,\mathsf{xor}\, (z_3 \,\mathsf{rshift}\, \ell)$.

```
template<class UIntType, size_t w, size_t n, size_t m, size_t r,
         UIntType a, size_t u, UIntType d, size_t s,
         UIntType b, size_t t,
         UIntType c, size_t l, UIntType f>
 class mersenne_twister_engine
{
```

275) The name of this engine refers, in part, to a property of its period: For properly-selected values of the parameters, the period is closely related to a large Mersenne prime number.

```
public:
 // types
 typedef UIntType result_type;

 // engine characteristics
 static constexpr size_t word_size = w;
 static constexpr size_t state_size = n;
 static constexpr size_t shift_size = m;
 static constexpr size_t mask_bits = r;
 static constexpr UIntType xor_mask = a;
 static constexpr size_t tempering_u = u;
 static constexpr UIntType tempering_d = d;
 static constexpr size_t tempering_s = s;
 static constexpr UIntType tempering_b = b;
 static constexpr size_t tempering_t = t;
 static constexpr UIntType tempering_c = c;
 static constexpr size_t tempering_l = l;
 static constexpr UIntType initialization_multiplier = f;
 static constexpr result_type min() { return 0; }
 static constexpr result_type max() { return  2^w - 1; }
 static constexpr result_type default_seed = 5489u;

 // constructors and seeding functions
 explicit mersenne_twister_engine(result_type value = default_seed);
 template<class Sseq> explicit mersenne_twister_engine(Sseq& q);
 void seed(result_type value = default_seed);
 template<class Sseq> void seed(Sseq& q);

 // generating functions
 result_type operator()();
 void discard(unsigned long long z);
};
```

3 The following relations shall hold: `0 < m`, `m <= n`, `2u < w`, `r <= w`, `u <= w`, `s <= w`, `t <= w`, `l <= w`, `w <= numeric_limits<UIntType>::digits`, `a <= (1u<<w) - 1u`, `b <= (1u<<w) - 1u`, `c <= (1u<<w) - 1u`, `d <= (1u<<w) - 1u`, and `f <= (1u<<w) - 1u`.

4 The textual representation of $\mathtt{x}_i$ consists of the values of $X_{i-n}, \ldots, X_{i-1}$, in that order.

`explicit mersenne_twister_engine(result_type value = default_seed);`

5 *Effects:* Constructs a `mersenne_twister_engine` object. Sets X_{-n} to `value` mod 2^w. Then, iteratively for $i = 1-n, \ldots, -1$, sets X_i to

$$\left[f \cdot \left(X_{i-1} \,\mathsf{xor}\, \left(X_{i-1} \,\mathsf{rshift}\, (w-2)\right)\right) + i \bmod n\right] \bmod 2^w \ .$$

6 *Complexity:* $\mathscr{O}(n)$.

`template<class Sseq> explicit mersenne_twister_engine(Sseq& q);`

7 *Effects:* Constructs a `mersenne_twister_engine` object. With $k = \lceil w/32 \rceil$ and a an array (or equivalent) of length $n \cdot k$, invokes `q.generate(`$a + 0$`, `$a + n \cdot k$`)` and then, iteratively for $i = -n, \ldots, -1$, sets X_i to $\left(\sum_{j=0}^{k-1} a_{k(i+n)+j} \cdot 2^{32j}\right) \bmod 2^w$. Finally, if the most significant $w - r$ bits of X_{-n} are zero, and if each of the other resulting X_i is 0, changes X_{-n} to 2^{w-1}.

26.101.0.1 Class template `subtract_with_carry_engine` [rand.eng.sub]

1 A `subtract_with_carry_engine` random number engine produces unsigned integer random numbers.

2 The state $\mathtt{x}_i$ of a `subtract_with_carry_engine` object `x` is of size $\mathscr{O}(r)$, and consists of a sequence X of r integer values $0 \leq X_i < m = 2^w$; all subscripts applied to X are to be taken modulo r. The state $\mathtt{x}_i$ additionally consists of an integer c (known as the *carry*) whose value is either 0 or 1.

3 The state transition is performed as follows:

a) Let $Y = X_{i-s} - X_{i-r} - c$.

b) Set X_i to $y = Y \bmod m$. Set c to 1 if $Y < 0$, otherwise set c to 0.

[*Note:* This algorithm corresponds to a modular linear function of the form $\mathsf{TA}(\mathtt{x}_i) = (a \cdot \mathtt{x}_i) \bmod b$, where b is of the form $m^r - m^s + 1$ and $a = b - (b-1)/m$. — *end note*]

4 The generation algorithm is given by $\mathsf{GA}(\mathtt{x}_i) = y$, where y is the value produced as a result of advancing the engine's state as described above.

```
template<class UIntType, size_t w, size_t s, size_t r>
 class subtract_with_carry_engine
{
public:
 // types
 typedef UIntType result_type;

 // engine characteristics
 static constexpr size_t word_size = w;
 static constexpr size_t short_lag = s;
 static constexpr size_t long_lag = r;
 static constexpr result_type min() { return 0; }
 static constexpr result_type max() { return m − 1; }
 static constexpr result_type default_seed = 19780503u;

 // constructors and seeding functions
 explicit subtract_with_carry_engine(result_type value = default_seed);
 template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
 void seed(result_type value = default_seed);
 template<class Sseq> void seed(Sseq& q);

 // generating functions
 result_type operator()();
 void discard(unsigned long long z);
};
```

5 The following relations shall hold: `0u < s`, `s < r`, `0 < w`, and `w <= numeric_limits<UIntType>::digits`.

6 The textual representation consists of the values of $X_{i-r}, \ldots, X_{i-1}$, in that order, followed by c.

`explicit subtract_with_carry_engine(result_type value = default_seed);`

7 *Effects:* Constructs a `subtract_with_carry_engine` object. Sets the values of $X_{-r}, \ldots, X_{-1}$, in that order, as specified below. If X_{-1} is then 0, sets c to 1; otherwise sets c to 0.

To set the values X_k, first construct `e`, a `linear_congruential_engine` object, as if by the following definition:

```
linear_congruential_engine<result_type,
                           40014u,0u,2147483563u> e(value == 0u ? default_seed : value);
```

Then, to set each X_k, obtain new values $z_0, \ldots, z_{n-1}$ from $n = \lceil w/32 \rceil$ successive invocations of `e` taken modulo 2^{32}. Set X_k to $\left(\sum_{j=0}^{n-1} z_j \cdot 2^{32j}\right) \bmod m$.

8 *Complexity:* Exactly $n \cdot$ `r` invocations of `e`.

```
template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
```

9 *Effects:* Constructs a `subtract_with_carry_engine` object. With $k = \lceil w/32 \rceil$ and a an array (or equivalent) of length $r \cdot k$, invokes `q.generate(`$a+0$`, `$a+r \cdot k$`)` and then, iteratively for $i = -r, \ldots, -1$, sets X_i to $\left(\sum_{j=0}^{k-1} a_{k(i+r)+j} \cdot 2^{32j}\right) \bmod m$. If X_{-1} is then 0, sets c to 1; otherwise sets c to 0.

26.101.1 Random number engine adaptor class templates [rand.adapt]

26.101.1.1 In general [rand.adapt.general]

1 Each type instantiated from a class template specified in this section 26.97.2 satisfies the requirements of a random number engine adaptor (26.88.0.1) type.

2 Except where specified otherwise, the complexity of each function specified in this section 26.101.1 is constant.

3 Except where specified otherwise, no function described in this section 26.101.1 throws an exception.

4 Descriptions are provided in this section 26.101.1 only for adaptor operations that are not described in section 26.88.0.1 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

5 Each template specified in this section 26.101.1 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

26.101.1.2 Class template `discard_block_engine` [rand.adapt.disc]

1 A `discard_block_engine` random number engine adaptor produces random numbers selected from those produced by some base engine e. The state $\mathtt{x}_i$ of a `discard_block_engine` engine adaptor object `x` consists of the state $\mathtt{e}_i$ of its base engine `e` and an additional integer n. The size of the state is the size of e's state plus 1.

2 The transition algorithm discards all but $r > 0$ values from each block of $p \geq r$ values delivered by e. The state transition is performed as follows: If $n \geq r$, advance the state of `e` from $\mathtt{e}_i$ to $\mathtt{e}_{i+p-r}$ and set n to 0. In any case, then increment n and advance `e`'s then-current state $\mathtt{e}_j$ to $\mathtt{e}_{j+1}$.

3 The generation algorithm yields the value returned by the last invocation of `e()` while advancing `e`'s state as described above.

```
template<class Engine, size_t p, size_t r>
 class discard_block_engine
{
public:
 // types
 typedef typename Engine::result_type result_type;

 // engine characteristics
 static constexpr size_t block_size = p;
 static constexpr size_t used_block = r;
 static constexpr result_type min() { return Engine::min(); }
 static constexpr result_type max() { return Engine::max(); }

 // constructors and seeding functions
 discard_block_engine();
```

```
  explicit discard_block_engine(const Engine& e);
  explicit discard_block_engine(Engine&& e);
  explicit discard_block_engine(result_type s);
  template<class Sseq> explicit discard_block_engine(Sseq& q);
  void seed();
  void seed(result_type s);
  template<class Sseq> void seed(Sseq& q);

  // generating functions
  result_type operator()();
  void discard(unsigned long long z);

  // property functions
  const Engine& base() const noexcept { return e; };

 private:
  Engine e;    // exposition only
  int n;       // exposition only
 };
```

4 The following relations shall hold: `0 < r` and `r <= p`.

5 The textual representation consists of the textual representation of `e` followed by the value of `n`.

6 In addition to its behavior pursuant to section 26.88.0.1, each constructor that is not a copy constructor sets `n` to 0.

26.101.1.3 Class template `independent_bits_engine` [rand.adapt.ibits]

1 An `independent_bits_engine` random number engine adaptor combines random numbers that are produced by some base engine e, so as to produce random numbers with a specified number of bits w. The state $\mathtt{x}_i$ of an `independent_bits_engine` engine adaptor object `x` consists of the state $\mathtt{e}_i$ of its base engine `e`; the size of the state is the size of e's state.

2 The transition and generation algorithms are described in terms of the following integral constants:

a) Let $R =$ `e.max() - e.min() + 1` and $m = \lfloor \log_2 R \rfloor$.

b) With n as determined below, let $w_0 = \lfloor w/n \rfloor$, $n_0 = n - w \bmod n$, $y_0 = 2^{w_0} \lfloor R/2^{w_0} \rfloor$, and $y_1 = 2^{w_0+1} \lfloor R/2^{w_0+1} \rfloor$.

c) Let $n = \lceil w/m \rceil$ if and only if the relation $R - y_0 \leq \lfloor y_0/n \rfloor$ holds as a result. Otherwise let $n = 1 + \lceil w/m \rceil$.

[*Note:* The relation $w = n_0 w_0 + (n - n_0)(w_0 + 1)$ always holds. — *end note*]

3 The transition algorithm is carried out by invoking `e()` as often as needed to obtain n_0 values less than y_0 +`e.min()` and $n - n_0$ values less than $y_1 +$ `e.min()`.

4 The generation algorithm uses the values produced while advancing the state as described above to yield a quantity S obtained as if by the following algorithm:

```
S = 0;
for (k = 0; k ≠ n0; k += 1)  {
 do u = e() - e.min(); while (u ≥ y0);
 S = 2^w0 · S + u mod 2^w0;
}
for (k = n0; k ≠ n; k += 1)  {
```

```
 do u = e() - e.min(); while (u ≥ y1);
 S = 2^(w0+1) · S + u mod 2^(w0+1);
}

template<class Engine, size_t w, class UIntType>
class independent_bits_engine
{
public:
 // types
 typedef UIntType result_type;

 // engine characteristics
 static constexpr result_type min() { return 0; }
 static constexpr result_type max() { return 2^w − 1; }

 // constructors and seeding functions
 independent_bits_engine();
 explicit independent_bits_engine(const Engine& e);
 explicit independent_bits_engine(Engine&& e);
 explicit independent_bits_engine(result_type s);
 template<class Sseq> explicit independent_bits_engine(Sseq& q);
 void seed();
 void seed(result_type s);
 template<class Sseq> void seed(Sseq& q);

 // generating functions
 result_type operator()();
 void discard(unsigned long long z);

 // property functions
 const Engine& base() const noexcept { return e; };

private:
 Engine e;    // exposition only
};
```

5 The following relations shall hold: `0 < w` and `w <= numeric_limits<result_type>::digits`.

6 The textual representation consists of the textual representation of `e`.

26.101.1.4 Class template `shuffle_order_engine` [rand.adapt.shuf]

1 A `shuffle_order_engine` random number engine adaptor produces the same random numbers that are produced by some base engine e, but delivers them in a different sequence. The state $\mathtt{x}_i$ of a `shuffle_order_engine` engine adaptor object `x` consists of the state $\mathtt{e}_i$ of its base engine `e`, an additional value Y of the type delivered by `e`, and an additional sequence V of k values also of the type delivered by `e`. The size of the state is the size of e's state plus $k + 1$.

2 The transition algorithm permutes the values produced by e. The state transition is performed as follows:

a) Calculate an integer $j = \left\lfloor \frac{k \cdot (Y - e_{\min})}{e_{\max} - e_{\min} + 1} \right\rfloor$.

b) Set Y to V_j and then set V_j to `e()`.

3 The generation algorithm yields the last value of `Y` produced while advancing `e`'s state as described above.

```
template<class Engine, size_t k>
 class shuffle_order_engine
{
public:
 // types
 typedef typename Engine::result_type result_type;

 // engine characteristics
 static constexpr size_t table_size = k;
 static constexpr result_type min() { return Engine::min(); }
 static constexpr result_type max() { return Engine::max(); }

 // constructors and seeding functions
 shuffle_order_engine();
 explicit shuffle_order_engine(const Engine& e);
 explicit shuffle_order_engine(Engine&& e);
 explicit shuffle_order_engine(result_type s);
 template<class Sseq> explicit shuffle_order_engine(Sseq& q);
 void seed();
 void seed(result_type s);
 template<class Sseq> void seed(Sseq& q);

 // generating functions
 result_type operator()();
 void discard(unsigned long long z);

 // property functions
 const Engine& base() const noexcept { return e; };

private:
 Engine e;           // exposition only
 result_type Y;      // exposition only
 result_type V[k];   // exposition only
};
```

4 The following relation shall hold: `0 < k`.

5 The textual representation consists of the textual representation of `e`, followed by the `k` values of V, followed by the value of Y.

6 In addition to its behavior pursuant to section 26.88.0.1, each constructor that is not a copy constructor initializes `V[0]`, . . . , `V[k-1]` and Y, in that order, with values returned by successive invocations of `e()`.

26.101.2 Engines and engine adaptors with predefined parameters [rand.predef]

```
typedef linear_congruential_engine<uint_fast32_t, 16807, 0, 2147483647>
      minstd_rand0;
```

1 *Required behavior:* The 10000 th consecutive invocation of a default-constructed object of type `minstd_rand0` shall produce the value 1043618065.

```
typedef linear_congruential_engine<uint_fast32_t, 48271, 0, 2147483647>
      minstd_rand;
```

2 *Required behavior:* The 10000 th consecutive invocation of a default-constructed object of type `minstd_rand` shall produce the value 399268537.

```
typedef mersenne_twister_engine<uint_fast32_t,
        32,624,397,31,0x9908b0df,11,0xffffffff,7,0x9d2c5680,15,0xefc60000,18,1812433253>
        mt19937;
```

3 *Required behavior:* The 10000 th consecutive invocation of a default-constructed object of type `mt19937` shall produce the value 4123659995.

```
typedef mersenne_twister_engine<uint_fast64_t,
        64,312,156,31,0xb5026f5aa96619e9,29,
        0x5555555555555555,17,
        0x71d67fffeda60000,37,
        0xfff7eee000000000,43,
        6364136223846793005>
        mt19937_64;
```

1 *Required behavior:* The 10000 th consecutive invocation of a default-constructed object of type `mt19937_64` shall produce the value 9981545732273789042.

```
typedef subtract_with_carry_engine<uint_fast32_t, 24, 10, 24>
        ranlux24_base;
```

2 *Required behavior:* The 10000 th consecutive invocation of a default-constructed object of type `ranlux24_base` shall produce the value 7937952.

```
typedef subtract_with_carry_engine<uint_fast64_t, 48, 5, 12>
        ranlux48_base;
```

3 *Required behavior:* The 10000 th consecutive invocation of a default-constructed object of type `ranlux48_base` shall produce the value 61839128582725.

```
typedef discard_block_engine<ranlux24_base, 223, 23>
        ranlux24;
```

4 *Required behavior:* The 10000 th consecutive invocation of a default-constructed object of type `ranlux24` shall produce the value 9901578.

```
typedef discard_block_engine<ranlux48_base, 389, 11>
        ranlux48;
```

5 *Required behavior:* The 10000 th consecutive invocation of a default-constructed object of type `ranlux48` shall produce the value 249142670248501.

```
typedef shuffle_order_engine<minstd_rand0,256>
        knuth_b;
```

6 *Required behavior:* The 10000 th consecutive invocation of a default-constructed object of type `knuth_b` shall produce the value 1112339016.

```
typedef implementation-defined
        default_random_engine;
```

7 *Remark:* The choice of engine type named by this `typedef` is implementation-defined. [*Note:* The implementation may select this type on the basis of performance, size, quality, or any combination of such factors, so as to provide at least acceptable engine behavior for relatively casual, inexpert, and/or lightweight use. Because different implementations may select different underlying engine types, code that uses this `typedef` need not generate identical sequences across implementations. — *end note*]

26.105.1 Class random_device [rand.device]

1

A random_device uniform random number generator produces non-deterministic random numbers.

1

If implementation limitations prevent generating non-deterministic random numbers, the implementation may employ a random number engine.

```
class random_device
{
public:
 // types
 typedef unsigned int result_type;

 // generator characteristics
 static constexpr result_type min() { return numeric_limits<result_type>::min(); }
 static constexpr result_type max() { return numeric_limits<result_type>::max(); }

 // constructors
 explicit random_device(const string& token = implementation-defined);

 // generating functions
 result_type operator()();

 // property functions
 double entropy() const noexcept;

 // no copy functions
 random_device(const random_device& ) = delete;
 void operator=(const random_device& ) = delete;
};
```

`explicit random_device(const string& token = implementation-defined);`

1 *Effects:* Constructs a random_device non-deterministic uniform random number generator object. The semantics and default value of the token parameter are implementation-defined.[276]

2

Throws: A value of an implementation-defined type derived from exception if the random_device could not be initialized.

`double entropy() const noexcept;`

1 *Returns:* If the implementation employs a random number engine, returns 0.0. Otherwise, returns an entropy estimate[277] for the random numbers returned by operator(), in the range min() to $\log_2(\texttt{max()} + 1)$.

`result_type operator()();`

2 *Returns:* A non-deterministic random value, uniformly distributed between min() and max(), inclusive. It is implementation-defined how these values are generated.

1 *Throws:* A value of an implementation-defined type derived from exception if a random number could not be obtained.

276) The parameter is intended to allow an implementation to differentiate between different sources of randomness.

277) If a device has n states whose respective probabilities are $P_0, \ldots, P_{n-1}$, the device entropy S is defined as $S = -\sum_{i=0}^{n-1} P_i \cdot \log P_i$.

26.111.1 Utilities [rand.util]

26.111.1.1 Class seed_seq [rand.util.seedseq]

```
class seed_seq
{
public:
 // types
 typedef uint_least32_t result_type;

 // constructors
 seed_seq();
 template<class T>
   seed_seq(initializer_list<T> il);
 template<class InputIterator>
   seed_seq(InputIterator begin, InputIterator end);

 // generating functions
 template<class RandomAccessIterator>
   void generate(RandomAccessIterator begin, RandomAccessIterator end);

 // property functions
 size_t size() const;
 template<class OutputIterator>
   void param(OutputIterator dest) const;

 // no copy functions
 seed_seq(const seed_seq& ) = delete;
 void operator=(const seed_seq& ) = delete;

private:
 vector<result_type> v;    // exposition only
};
```

`seed_seq();`

1 *Effects:* Constructs a `seed_seq` object as if by default-constructing its member `v`.

2 *Throws:* Nothing.

`template<class T>`
`seed_seq(initializer_list<T> il);`

3 *Requires:* `T` shall be an integer type.

4 *Effects:* Same as `seed_seq(il.begin(), il.end())`.

`template<class InputIterator>`
`seed_seq(InputIterator begin, InputIterator end);`

5 *Requires:* `InputIterator` shall satisfy the requirements of an input iterator (Table 107) type. Moreover, `iterator_traits<InputIterator>::value_type` shall denote an integer type.

6 *Effects:* Constructs a `seed_seq` object by the following algorithm:

```
for( InputIterator s = begin; s != end; ++s)
 v.push_back((*s) mod 2^32);
```

`template<class RandomAccessIterator>`
`void generate(RandomAccessIterator begin, RandomAccessIterator end);`

7 *Requires:* `RandomAccessIterator` shall meet the requirements of a mutable random access iterator (Table 111) type. Moreover, `iterator_traits<RandomAccessIterator>::value_type` shall denote an unsigned integer type capable of accommodating 32-bit quantities.

8 *Effects:* Does nothing if `begin == end`. Otherwise, with $s =$ `v.size()` and $n =$ `end` $-$ `begin`, fills the supplied range [`begin`, `end`) according to the following algorithm in which each operation is to be carried out modulo 2^{32}, each indexing operator applied to `begin` is to be taken modulo n, and $T(x)$ is defined as x xor (x rshift 27):

a) By way of initialization, set each element of the range to the value `0x8b8b8b8b`. Additionally, for use in subsequent steps, let $p = (n-t)/2$ and let $q = p + t$, where

$$t = (n \geq 623)\ ?\ 11 : (n \geq 68)\ ?\ 7 : (n \geq 39)\ ?\ 5 : (n \geq 7)\ ?\ 3 : (n-1)/2;$$

b) With m as the larger of $s+1$ and n, transform the elements of the range: iteratively for $k = 0, \ldots, m-1$, calculate values

$$\begin{aligned} r_1 &= 1664525 \cdot \mathtt{T}\,(\mathtt{begin}[k] \text{ xor } \mathtt{begin}[k+p] \text{ xor } \mathtt{begin}[k-1]) \\ r_2 &= r_1 + \begin{cases} s & , k = 0 \\ k \bmod n + \mathtt{v}[k-1] & , 0 < k \leq s \\ k \bmod n & , s < k \end{cases} \end{aligned}$$

and, in order, increment `begin`$[k+p]$ by r_1, increment `begin`$[k+q]$ by r_2, and set `begin[k]` to r_2.

c) Transform the elements of the range again, beginning where the previous step ended: iteratively for $k = m, \ldots, m+n-1$, calculate values

$$\begin{aligned} r_3 &= 1566083941 \cdot \mathtt{T}\,(\mathtt{begin}[k] + \mathtt{begin}[k+p] + \mathtt{begin}[k-1]) \\ r_4 &= r_3 - (k \bmod n) \end{aligned}$$

and, in order, update `begin`$[k+p]$ by xoring it with r_3, update `begin`$[k+q]$ by xoring it with r_4, and set `begin`$[k]$ to r_4.

9 *Throws:* What and when `RandomAccessIterator` operations of `begin` and `end` throw.

```
size_t size() const;
```

10 *Returns:* The number of 32-bit units that would be returned by a call to `param()`.

11 *Throws:* Nothing.

12 *Complexity:* Constant time.

```
template<class OutputIterator>
  void param(OutputIterator dest) const;
```

13 *Requires:* `OutputIterator` shall satisfy the requirements of an output iterator (Table 108) type. Moreover, the expression `*dest = rt` shall be valid for a value `rt` of type `result_type`.

14 *Effects:* Copies the sequence of prepared 32-bit units to the given destination, as if by executing the following statement:

```
copy(v.begin(), v.end(), dest);
```

15 *Throws:* What and when `OutputIterator` operations of `dest` throw.

26.111.1.2 Function template `generate_canonical` [rand.util.canonical]

1

Each function instantiated from the template described in this section 26.111.1.2 maps the result of one or more invocations of a supplied uniform random number generator `g` to one member of the specified `RealType` such that, if the values g_i produced by `g` are uniformly distributed, the instantiation's results t_j, $0 \le t_j < 1$, are distributed as uniformly as possible as specified below.

1 [*Note:* Obtaining a value in this way can be a useful step in the process of transforming a value generated by a uniform random number generator into a value that can be delivered by a random number distribution. — *end note*]

```
template<class RealType, size_t bits, class URNG>
 RealType generate_canonical(URNG& g);
```

2 *Complexity:* Exactly $k = \max(1, \lceil b/\log_2 R \rceil)$ invocations of `g`, where b[278] is the lesser of `numeric_limits<RealType>::digits` and `bits`, and R is the value of `g.max()` − `g.min()` + 1.

3 *Effects:* Invokes `g()` k times to obtain values $g_0, \ldots, g_{k-1}$, respectively. Calculates a quantity

$$S = \sum_{i=0}^{k-1} (g_i - \texttt{g.min()}) \cdot R^i$$

using arithmetic of type `RealType`.

4 *Returns:* S/R^k.

5 *Throws:* What and when `g` throws.

26.113.1 Random number distribution class templates [rand.dist]

26.113.1.1 In general [rand.dist.general]

1 Each type instantiated from a class template specified in this section 26.113.1 satisfies the requirements of a random number distribution (26.88.0.2) type.

2 Descriptions are provided in this section 26.113.1 only for distribution operations that are not described in 26.88.0.2 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

3

The algorithms for producing each of the specified distributions are implementation-defined.

1 The value of each probability density function $p(z)$ and of each discrete probability function $P(z_i)$ specified in this section is 0 everywhere outside its stated domain.

26.118.0.1 Uniform distributions [rand.dist.uni]

26.118.0.1.1 Class template `uniform_int_distribution` [rand.dist.uni.int]

1

A `uniform_int_distribution` random number distribution produces random integers i, $a \le i \le b$, distributed according to the constant discrete probability function

$$P(i \mid a, b) = 1/(b - a + 1) \ .$$

278) b is introduced to avoid any attempt to produce more bits of randomness than can be held in `RealType`.

```
template<class IntType = int>
 class uniform_int_distribution
{
public:
 // types
 typedef IntType result_type;
 typedef unspecified param_type;

 // constructors and reset functions
 explicit uniform_int_distribution(IntType a = 0, IntType b = numeric_limits<IntType>::max());
 explicit uniform_int_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 result_type a() const;
 result_type b() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
};
```

`explicit uniform_int_distribution(IntType a = 0, IntType b = numeric_limits<IntType>::max());`

1 *Requires:* `a` $\leq$ `b`.

2 *Effects:* Constructs a `uniform_int_distribution` object; `a` and `b` correspond to the respective parameters of the distribution.

`result_type a() const;`

3 *Returns:* The value of the `a` parameter with which the object was constructed.

`result_type b() const;`

4 *Returns:* The value of the `b` parameter with which the object was constructed.

26.120.0.0.1 Class template `uniform_real_distribution` [rand.dist.uni.real]

1

A `uniform_real_distribution` random number distribution produces random numbers x, $a \leq x < b$, distributed according to the constant probability density function

$$p(x \mid a, b) = 1/(b - a) \ .$$

```
template<class RealType = double>
 class uniform_real_distribution
{
public:
 // types
 typedef RealType result_type;
```

```
  typedef unspecified param_type;

  // constructors and reset functions
  explicit uniform_real_distribution(RealType a = 0.0, RealType b = 1.0);
  explicit uniform_real_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URNG>
    result_type operator()(URNG& g);
  template<class URNG>
    result_type operator()(URNG& g, const param_type& parm);

  // property functions
  result_type a() const;
  result_type b() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
 };
```

`explicit uniform_real_distribution(RealType a = 0.0, RealType b = 1.0);`

1 *Requires:* `a` $\leq$ `b` and `b` $-$ `a` $\leq$ `numeric_limits<RealType>::max()`.

2 *Effects:* Constructs a `uniform_real_distribution` object; `a` and `b` correspond to the respective parameters of the distribution.

`result_type a() const;`

3 *Returns:* The value of the `a` parameter with which the object was constructed.

`result_type b() const;`

4 *Returns:* The value of the `b` parameter with which the object was constructed.

26.122.0.1 Bernoulli distributions [rand.dist.bern]

26.122.0.1.1 Class `bernoulli_distribution` [rand.dist.bern.bernoulli]

1 A `bernoulli_distribution` random number distribution produces `bool` values b distributed according to the discrete probability function

$$P(b \mid p) = \begin{cases} p & \text{if} \quad b = \texttt{true} \\ 1 - p & \text{if} \quad b = \texttt{false} \end{cases} .$$

```
 class bernoulli_distribution
 {
 public:
  // types
  typedef bool result_type;
  typedef unspecified param_type;

  // constructors and reset functions
  explicit bernoulli_distribution(double p = 0.5);
  explicit bernoulli_distribution(const param_type& parm);
```

```
  void reset();

  // generating functions
  template<class URNG>
    result_type operator()(URNG& g);
  template<class URNG>
    result_type operator()(URNG& g, const param_type& parm);

  // property functions
  double p() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
 };
```

`explicit bernoulli_distribution(double p = 0.5);`

2 *Requires:* $0 \leq \mathtt{p} \leq 1$.

3 *Effects:* Constructs a `bernoulli_distribution` object; `p` corresponds to the parameter of the distribution.

`double p() const;`

4 *Returns:* The value of the `p` parameter with which the object was constructed.

26.122.0.1.2 Class template `binomial_distribution` [rand.dist.bern.bin]

1 A `binomial_distribution` random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function

$$P(i \mid t, p) = \binom{t}{i} \cdot p^i \cdot (1-p)^{t-i} \ .$$

```
template<class IntType = int>
 class binomial_distribution
{
public:
 // types
 typedef IntType result_type;
 typedef unspecified param_type;

 // constructors and reset functions
 explicit binomial_distribution(IntType t = 1, double p = 0.5);
 explicit binomial_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 IntType t() const;
 double p() const;
```

```
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
 };
```

```
explicit binomial_distribution(IntType t = 1, double p = 0.5);
```

2 *Requires:* $0 \leq \mathtt{p} \leq 1$ and $0 \leq \mathtt{t}$.

3 *Effects:* Constructs a `binomial_distribution` object; `t` and `p` correspond to the respective parameters of the distribution.

```
IntType t() const;
```

4 *Returns:* The value of the `t` parameter with which the object was constructed.

```
double p() const;
```

5 *Returns:* The value of the `p` parameter with which the object was constructed.

26.122.0.1.3 Class template `geometric_distribution` [rand.dist.bern.geo]

1 A `geometric_distribution` random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function

$$P(i \mid p) = p \cdot (1 - p)^i \ .$$

```
template<class IntType = int>
 class geometric_distribution
{
public:
 // types
 typedef IntType result_type;
 typedef unspecified param_type;

 // constructors and reset functions
 explicit geometric_distribution(double p = 0.5);
 explicit geometric_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 double p() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
 };
```

```
explicit geometric_distribution(double p = 0.5);
```

2 *Requires:* $0 < \mathtt{p} < 1$.

3 *Effects:* Constructs a `geometric_distribution` object; `p` corresponds to the parameter of the distribution.

```
double p() const;
```

4 *Returns:* The value of the `p` parameter with which the object was constructed.

26.122.0.1.4 Class template `negative_binomial_distribution` [rand.dist.bern.negbin]

1 A `negative_binomial_distribution` random number distribution produces random integers $i \geq 0$ distributed according to the discrete probability function

$$P(i \mid k, p) = \binom{k+i-1}{i} \cdot p^k \cdot (1-p)^i \ .$$

```
template<class IntType = int>
 class negative_binomial_distribution
{
public:
 // types
 typedef IntType  result_type;
 typedef unspecified param_type;

 // constructor and reset functions
 explicit negative_binomial_distribution(IntType k = 1, double p = 0.5);
 explicit negative_binomial_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 IntType k() const;
 double p() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
};
```

```
explicit negative_binomial_distribution(IntType k = 1, double p = 0.5);
```

2 *Requires:* $0 < \mathtt{p} \leq 1$ and $0 < \mathtt{k}$.

3 *Effects:* Constructs a `negative_binomial_distribution` object; `k` and `p` correspond to the respective parameters of the distribution.

```
IntType k() const;
```

4 *Returns:* The value of the `k` parameter with which the object was constructed.

```
double p() const;
```

5 *Returns:* The value of the `p` parameter with which the object was constructed.

26.122.0.2 Poisson distributions [rand.dist.pois]

26.122.0.2.1 Class template `poisson_distribution` [rand.dist.pois.poisson]

1 A `poisson_distribution` random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function

$$P(i \mid \mu) = \frac{e^{-\mu}\mu^i}{i\,!} \ .$$

The distribution parameter μ is also known as this distribution's *mean* .

```
template<class IntType = int>
 class poisson_distribution
{
public:
 // types
 typedef IntType result_type;
 typedef unspecified param_type;

 // constructors and reset functions
 explicit poisson_distribution(double mean = 1.0);
 explicit poisson_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 double mean() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
};
```

`explicit poisson_distribution(double mean = 1.0);`

2 *Requires:* $0 <$ `mean`.

3 *Effects:* Constructs a `poisson_distribution` object; `mean` corresponds to the parameter of the distribution.

`double mean() const;`

4 *Returns:* The value of the `mean` parameter with which the object was constructed.

26.122.0.2.2 Class template `exponential_distribution` [rand.dist.pois.exp]

1 An `exponential_distribution` random number distribution produces random numbers $x > 0$ distributed according to the probability density function

$$p(x \mid \lambda) = \lambda e^{-\lambda x} \ .$$

```
template<class RealType = double>
 class exponential_distribution
{
```

```
public:
 // types
 typedef RealType result_type;
 typedef unspecified param_type;

 // constructors and reset functions
 explicit exponential_distribution(RealType lambda = 1.0);
 explicit exponential_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 RealType lambda() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
};
```

`explicit exponential_distribution(RealType lambda = 1.0);`

2 *Requires:* $0 <$ `lambda`.

3 *Effects:* Constructs a `exponential_distribution` object; `lambda` corresponds to the parameter of the distribution.

`RealType lambda() const;`

4 *Returns:* The value of the `lambda` parameter with which the object was constructed.

26.122.0.2.3 Class template `gamma_distribution` [rand.dist.pois.gamma]

1 A `gamma_distribution` random number distribution produces random numbers $x > 0$ distributed according to the probability density function

$$p(x \mid \alpha, \beta) = \frac{e^{-x/\beta}}{\beta^\alpha \cdot \Gamma(\alpha)} \cdot x^{\alpha-1} .$$

```
template<class RealType = double>
 class gamma_distribution
{
public:
 // types
 typedef RealType result_type;
 typedef unspecified param_type;

 // constructors and reset functions
 explicit gamma_distribution(RealType alpha = 1.0, RealType beta = 1.0);
 explicit gamma_distribution(const param_type& parm);
 void reset();
```

```
  // generating functions
  template<class URNG>
    result_type operator()(URNG& g);
  template<class URNG>
    result_type operator()(URNG& g, const param_type& parm);

  // property functions
  RealType alpha() const;
  RealType beta() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
};
```

```
explicit gamma_distribution(RealType alpha = 1.0, RealType beta = 1.0);
```

2 *Requires:* $0 <$ `alpha` and $0 <$ `beta`.

3 *Effects:* Constructs a `gamma_distribution` object; `alpha` and `beta` correspond to the parameters of the distribution.

```
RealType alpha() const;
```

4 *Returns:* The value of the `alpha` parameter with which the object was constructed.

```
RealType beta() const;
```

5 *Returns:* The value of the `beta` parameter with which the object was constructed.

26.122.0.2.4 Class template `weibull_distribution` [rand.dist.pois.weibull]

1 A `weibull_distribution` random number distribution produces random numbers $x \geq 0$ distributed according to the probability density function

$$p(x \mid a, b) = \frac{a}{b} \cdot \left(\frac{x}{b}\right)^{a-1} \cdot \exp\left(-\left(\frac{x}{b}\right)^{a}\right) .$$

```
template<class RealType = double>
 class weibull_distribution
{
public:
 // types
 typedef RealType result_type;
 typedef unspecified param_type;

 // constructor and reset functions
 explicit weibull_distribution(RealType a = 1.0, RealType b = 1.0);
 explicit weibull_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);
```

```
  // property functions
  RealType a() const;
  RealType b() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
 };
```

```
explicit weibull_distribution(RealType a = 1.0, RealType b = 1.0);
```

2 *Requires:* $0 <$ `a` and $0 <$ `b`.

3 *Effects:* Constructs a `weibull_distribution` object; `a` and `b` correspond to the respective parameters of the distribution.

```
RealType a() const;
```

4 *Returns:* The value of the `a` parameter with which the object was constructed.

```
RealType b() const;
```

5 *Returns:* The value of the `b` parameter with which the object was constructed.

26.122.0.2.5 Class template `extreme_value_distribution` [rand.dist.pois.extreme]

1 An `extreme_value_distribution` random number distribution produces random numbers x distributed according to the probability density function[279]

$$p(x \mid a, b) = \frac{1}{b} \cdot \exp\left(\frac{a-x}{b} - \exp\left(\frac{a-x}{b}\right)\right) .$$

```
 template<class RealType = double>
  class extreme_value_distribution
 {
 public:
  // types
  typedef RealType result_type;
  typedef unspecified param_type;

  // constructor and reset functions
  explicit extreme_value_distribution(RealType a = 0.0, RealType b = 1.0);
  explicit extreme_value_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URNG>
    result_type operator()(URNG& g);
  template<class URNG>
    result_type operator()(URNG& g, const param_type& parm);

  // property functions
  RealType a() const;
  RealType b() const;
```

279) The distribution corresponding to this probability density function is also known (with a possible change of variable) as the Gumbel Type I, the log-Weibull, or the Fisher-Tippett Type I distribution.

```
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
 };
```

```
explicit extreme_value_distribution(RealType a = 0.0, RealType b = 1.0);
```

2 *Requires:* $0 < \texttt{b}$.

3 *Effects:* Constructs an `extreme_value_distribution` object; `a` and `b` correspond to the respective parameters of the distribution.

```
RealType a() const;
```

4 *Returns:* The value of the `a` parameter with which the object was constructed.

```
RealType b() const;
```

5 *Returns:* The value of the `b` parameter with which the object was constructed.

26.122.0.3 Normal distributions [rand.dist.norm]

26.122.0.3.1 Class template `normal_distribution` [rand.dist.norm.normal]

1

A `normal_distribution` random number distribution produces random numbers x distributed according to the probability density function

$$p(x \mid \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \cdot \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right).$$

The distribution parameters μ and σ are also known as this distribution's *mean* and *standard deviation* .

```
template<class RealType = double>
 class normal_distribution
{
public:
 // types
 typedef RealType result_type;
 typedef unspecified param_type;

 // constructors and reset functions
 explicit normal_distribution(RealType mean = 0.0, RealType stddev = 1.0);
 explicit normal_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 RealType mean() const;
 RealType stddev() const;
 param_type param() const;
 void param(const param_type& parm);
```

```
  result_type min() const;
  result_type max() const;
 };
```

```
explicit normal_distribution(RealType mean = 0.0, RealType stddev = 1.0);
```

1 *Requires:* $0 <$ `stddev`.

2 *Effects:* Constructs a `normal_distribution` object; `mean` and `stddev` correspond to the respective parameters of the distribution.

```
RealType mean() const;
```

3 *Returns:* The value of the `mean` parameter with which the object was constructed.

```
RealType stddev() const;
```

4 *Returns:* The value of the `stddev` parameter with which the object was constructed.

26.128.0.0.1 Class template `lognormal_distribution` [rand.dist.norm.lognormal]

1 A `lognormal_distribution` random number distribution produces random numbers $x > 0$ distributed according to the probability density function

$$p(x \mid m, s) = \frac{1}{sx\sqrt{2\pi}} \cdot \exp\left(-\frac{(\ln x - m)^2}{2s^2}\right).$$

```
template<class RealType = double>
 class lognormal_distribution
{
public:
 // types
 typedef RealType result_type;
 typedef unspecified param_type;

 // constructor and reset functions
 explicit lognormal_distribution(RealType m = 0.0, RealType s = 1.0);
 explicit lognormal_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 RealType m() const;
 RealType s() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
};
```

```
explicit lognormal_distribution(RealType m = 0.0, RealType s = 1.0);
```

2 *Requires:* $0 <$ `s`.

3 *Effects:* Constructs a `lognormal_distribution` object; `m` and `s` correspond to the respective parameters of the distribution.

```
RealType m() const;
```

4 *Returns:* The value of the `m` parameter with which the object was constructed.

```
RealType s() const;
```

5 *Returns:* The value of the `s` parameter with which the object was constructed.

26.128.0.0.2 Class template `chi_squared_distribution` [rand.dist.norm.chisq]

1 A `chi_squared_distribution` random number distribution produces random numbers $x > 0$ distributed according to the probability density function

$$p(x \mid n) = \frac{x^{(n/2)-1} \cdot e^{-x/2}}{\Gamma(n/2) \cdot 2^{n/2}} \ .$$

```
template<class RealType = double>
 class chi_squared_distribution
{
public:
 // types
 typedef RealType result_type;
 typedef unspecified param_type;

 // constructor and reset functions
 explicit chi_squared_distribution(RealType n = 1);
 explicit chi_squared_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 RealType n() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
};
```

```
explicit chi_squared_distribution(RealType n = 1);
```

2 *Requires:* $0 <$ `n`.

3 *Effects:* Constructs a `chi_squared_distribution` object; `n` corresponds to the parameter of the distribution.

```
RealType n() const;
```

4 *Returns:* The value of the `n` parameter with which the object was constructed.

26.128.0.0.3 Class template `cauchy_distribution` [rand.dist.norm.cauchy]

1 A `cauchy_distribution` random number distribution produces random numbers x distributed according to the probability density function

$$p(x \mid a, b) = \left(\pi b \left(1 + \left(\frac{x-a}{b}\right)^2\right)\right)^{-1} .$$

```
template<class RealType = double>
 class cauchy_distribution
{
public:
 // types
 typedef RealType result_type;
 typedef unspecified param_type;

 // constructor and reset functions
 explicit cauchy_distribution(RealType a = 0.0, RealType b = 1.0);
 explicit cauchy_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 RealType a() const;
 RealType b() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
};
```

`explicit cauchy_distribution(RealType a = 0.0, RealType b = 1.0);`

2 *Requires:* $0 <$ `b`.

3 *Effects:* Constructs a `cauchy_distribution` object; `a` and `b` correspond to the respective parameters of the distribution.

`RealType a() const;`

4 *Returns:* The value of the `a` parameter with which the object was constructed.

`RealType b() const;`

5 *Returns:* The value of the `b` parameter with which the object was constructed.

26.128.0.0.4 Class template `fisher_f_distribution` [rand.dist.norm.f]

1 A `fisher_f_distribution` random number distribution produces random numbers $x \geq 0$ distributed according to the probability density function

$$p(x \mid m, n) = \frac{\Gamma\big((m+n)/2\big)}{\Gamma(m/2)\,\Gamma(n/2)} \cdot \left(\frac{m}{n}\right)^{m/2} \cdot x^{(m/2)-1} \cdot \left(1 + \frac{mx}{n}\right)^{-(m+n)/2} .$$

```
template<class RealType = double>
 class fisher_f_distribution
{
public:
 // types
 typedef RealType result_type;
 typedef unspecified param_type;

 // constructor and reset functions
 explicit fisher_f_distribution(RealType m = 1, RealType n = 1);
 explicit fisher_f_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 RealType m() const;
 RealType n() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
};
```

`explicit fisher_f_distribution(RealType m = 1, RealType n = 1);`

2 *Requires:* $0 <$ `m` and $0 <$ `n`.

3 *Effects:* Constructs a `fisher_f_distribution` object; `m` and `n` correspond to the respective parameters of the distribution.

`RealType m() const;`

4 *Returns:* The value of the `m` parameter with which the object was constructed.

`RealType n() const;`

5 *Returns:* The value of the `n` parameter with which the object was constructed.

26.128.0.0.5 Class template `student_t_distribution` [rand.dist.norm.t]

1 A `student_t_distribution` random number distribution produces random numbers x distributed according to the probability density function

$$p(x \mid n) = \frac{1}{\sqrt{n\pi}} \cdot \frac{\Gamma\big((n+1)/2\big)}{\Gamma(n/2)} \cdot \left(1 + \frac{x^2}{n}\right)^{-(n+1)/2} .$$

```
template<class RealType = double>
 class student_t_distribution
{
public:
 // types
 typedef RealType result_type;
```

```
  typedef unspecified param_type;

  // constructor and reset functions
  explicit student_t_distribution(RealType n = 1);
  explicit student_t_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URNG>
    result_type operator()(URNG& g);
  template<class URNG>
    result_type operator()(URNG& g, const param_type& parm);

  // property functions
  RealType n() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
 };
```

`explicit student_t_distribution(RealType n = 1);`

2 *Requires:* $0 <$ `n`.

3 *Effects:* Constructs a `student_t_distribution` object; `n` corresponds to the parameter of the distribution.

`RealType n() const;`

4 *Returns:* The value of the `n` parameter with which the object was constructed.

26.128.0.1 Sampling distributions [rand.dist.samp]

26.128.0.1.1 Class template `discrete_distribution` [rand.dist.samp.discrete]

1 A `discrete_distribution` random number distribution produces random integers i, $0 \le i < n$, distributed according to the discrete probability function

$$P(i \,|\, p_0, \ldots, p_{n-1}) = p_i \ .$$

2 Unless specified otherwise, the distribution parameters are calculated as: $p_k = w_k/S$ for $k = 0, \ldots, n-1$, in which the values w_k, commonly known as the *weights* , shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: $0 < S = w_0 + \cdots + w_{n-1}$.

```
 template<class IntType = int>
  class discrete_distribution
 {
 public:
  // types
  typedef IntType result_type;
  typedef unspecified param_type;

  // constructor and reset functions
  discrete_distribution();
  template<class InputIterator>
    discrete_distribution(InputIterator firstW, InputIterator lastW);
```

```
  discrete_distribution(initializer_list<double> wl);
  template<class UnaryOperation>
    discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);
  explicit discrete_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URNG>
    result_type operator()(URNG& g);
  template<class URNG>
    result_type operator()(URNG& g, const param_type& parm);

  // property functions
  vector<double> probabilities() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
 };
```

`discrete_distribution();`

3 *Effects:* Constructs a `discrete_distribution` object with $n = 1$ and $p_0 = 1$. [*Note:* Such an object will always deliver the value 0. — *end note*]

```
template<class InputIterator>
  discrete_distribution(InputIterator firstW, InputIterator lastW);
```

4 *Requires:* `InputIterator` shall satisfy the requirements of an input iterator (Table 107) type. Moreover, `iterator_traits<InputIterator>::value_type` shall denote a type that is convertible to `double`. If `firstW == lastW`, let $n = 1$ and $w_0 = 1$. Otherwise, $\big[$`firstW`, `lastW`$\big)$ shall form a sequence w of length $n > 0$.

5 *Effects:* Constructs a `discrete_distribution` object with probabilities given by the formula above.

`discrete_distribution(initializer_list<double> wl);`

6 *Effects:* Same as `discrete_distribution(wl.begin(), wl.end())`.

```
template<class UnaryOperation>
  discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);
```

7 *Requires:* Each instance of type `UnaryOperation` shall be a function object (20.283) whose return type shall be convertible to `double`. Moreover, `double` shall be convertible to the type of `UnaryOperation`'s sole parameter. If `nw` $= 0$, let $n = 1$, otherwise let $n =$ `nw`. The relation $0 < \delta = (\texttt{xmax} - \texttt{xmin})/n$ shall hold.

8 *Effects:* Constructs a `discrete_distribution` object with probabilities given by the formula above, using the following values: If `nw` $= 0$, let $w_0 = 1$. Otherwise, let $w_k = \texttt{fw}(\texttt{xmin} + k \cdot \delta + \delta/2)$ for $k = 0, \ldots, n-1$.

9 *Complexity:* The number of invocations of `fw` shall not exceed n.

`vector<double> probabilities() const;`

10 *Returns:* A `vector<double>` whose `size` member returns n and whose `operator[]` member returns p_k when invoked with argument k for $k = 0, \ldots, n-1$.

26.128.0.1.2 Class template `piecewise_constant_distribution` [rand.dist.samp.pconst]

1 A `piecewise_constant_distribution` random number distribution produces random numbers x, $b_0 \le x < b_n$, uniformly distributed over each subinterval $[b_i, b_{i+1})$ according to the probability density function

$$p(x \mid b_0, \ldots, b_n,\ \rho_0, \ldots, \rho_{n-1}) = \rho_i \text{ , for } b_i \le x < b_{i+1} \text{ .}$$

2 The $n+1$ distribution parameters b_i, also known as this distribution's *interval boundaries* , shall satisfy the relation $b_i < b_{i+1}$ for $i = 0, \ldots, n-1$. Unless specified otherwise, the remaining n distribution parameters are calculated as:

$$\rho_k = \frac{w_k}{S \cdot (b_{k+1} - b_k)} \text{ for } k = 0, \ldots, n-1,$$

in which the values w_k, commonly known as the *weights* , shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: $0 < S = w_0 + \cdots + w_{n-1}$.

```
template<class RealType = double>
 class piecewise_constant_distribution
{
public:
 // types
 typedef RealType result_type;
 typedef unspecified param_type;

 // constructor and reset functions
 piecewise_constant_distribution();
 template<class InputIteratorB, class InputIteratorW>
   piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                   InputIteratorW firstW);
 template<class UnaryOperation>
   piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);
 template<class UnaryOperation>
   piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
 explicit piecewise_constant_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 vector<result_type> intervals() const;
 vector<result_type> densities() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
};
```

`piecewise_constant_distribution();`

3 *Effects:* Constructs a `piecewise_constant_distribution` object with $n = 1$, $\rho_0 = 1$, $b_0 = 0$, and $b_1 = 1$.

```
template<class InputIteratorB, class InputIteratorW>
 piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                 InputIteratorW firstW);
```

4 *Requires:* `InputIteratorB` and `InputIteratorW` shall each satisfy the requirements of an input iterator (Table 107) type. Moreover, `iterator_traits<InputIteratorB>::value_type` and `iterator_traits<InputIteratorW>::value_type` shall each denote a type that is convertible to `double`. If `firstB == lastB` or `++firstB == lastB`, let $n = 1$, $w_0 = 1$, $b_0 = 0$, and $b_1 = 1$. Otherwise, $\big[$`firstB`, `lastB`$\big)$ shall form a sequence b of length $n+1$, the length of the sequence w starting from `firstW` shall be at least n, and any w_k for $k \geq n$ shall be ignored by the distribution.

5 *Effects:* Constructs a `piecewise_constant_distribution` object with parameters as specified above.

```
template<class UnaryOperation>
 piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);
```

6 *Requires:* Each instance of type `UnaryOperation` shall be a function object (20.283) whose return type shall be convertible to `double`. Moreover, `double` shall be convertible to the type of `UnaryOperation`'s sole parameter.

7 *Effects:* Constructs a `piecewise_constant_distribution` object with parameters taken or calculated from the following values: If `bl.size()` < 2, let $n = 1$, $w_0 = 1$, $b_0 = 0$, and $b_1 = 1$. Otherwise, let $\big[$`bl.begin()`, `bl.end()`$\big)$ form a sequence $b_0, \ldots, b_n$, and let $w_k =$ `fw`$\big((b_{k+1}+b_k)/2\big)$ for $k = 0, \ldots, n–1$.

8 *Complexity:* The number of invocations of `fw` shall not exceed n.

```
template<class UnaryOperation>
 piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
```

9 *Requires:* Each instance of type `UnaryOperation` shall be a function object (20.283) whose return type shall be convertible to `double`. Moreover, `double` shall be convertible to the type of `UnaryOperation`'s sole parameter. If `nw` $= 0$, let $n = 1$, otherwise let $n =$ `nw`. The relation $0 < \delta = (\texttt{xmax} - \texttt{xmin})/n$ shall hold.

10 *Effects:* Constructs a `piecewise_constant_distribution` object with parameters taken or calculated from the following values: Let $b_k =$ `xmin`$+k\cdot\delta$ for $k = 0, \ldots, n$, and $w_k =$ `fw`$(b_k+\delta/2)$ for $k = 0, \ldots, n–1$.

11 *Complexity:* The number of invocations of `fw` shall not exceed n.

```
vector<result_type> intervals() const;
```

12 *Returns:* A `vector<result_type>` whose `size` member returns $n+1$ and whose `operator[]` member returns b_k when invoked with argument k for $k = 0, \ldots, n$.

```
vector<result_type> densities() const;
```

13 *Returns:* A `vector<result_type>` whose `size` member returns n and whose `operator[]` member returns ρ_k when invoked with argument k for $k = 0, \ldots, n-1$.

26.128.0.1.3 Class template `piecewise_linear_distribution` [rand.dist.samp.plinear]

1 A `piecewise_linear_distribution` random number distribution produces random numbers x, $b_0 \leq x < b_n$, distributed over each subinterval $[b_i, b_{i+1})$ according to the probability density function

$$p(x \mid b_0, \ldots, b_n,\ \rho_0, \ldots, \rho_n) = \rho_i \cdot \frac{b_{i+1} - x}{b_{i+1} - b_i} + \rho_{i+1} \cdot \frac{x - b_i}{b_{i+1} - b_i}\ , \text{ for } b_i \leq x < b_{i+1}\ .$$

2 The $n+1$ distribution parameters b_i, also known as this distribution's *interval boundaries* , shall satisfy the relation $b_i < b_{i+1}$ for $i = 0, \ldots, n-1$. Unless specified otherwise, the remaining $n+1$ distribution parameters

are calculated as $\rho_k = w_k/S$ for $k = 0, \ldots, n$, in which the values w_k, commonly known as the *weights at boundaries* , shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold:

$$0 < S = \frac{1}{2} \cdot \sum_{k=0}^{n-1} (w_k + w_{k+1}) \cdot (b_{k+1} - b_k) \ .$$

```
template<class RealType = double>
 class piecewise_linear_distribution
{
public:
 // types
 typedef RealType result_type;
 typedef unspecified param_type;

 // constructor and reset functions
 piecewise_linear_distribution();
 template<class InputIteratorB, class InputIteratorW>
   piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                 InputIteratorW firstW);
 template<class UnaryOperation>
   piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);
 template<class UnaryOperation>
   piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
 explicit piecewise_linear_distribution(const param_type& parm);
 void reset();

 // generating functions
 template<class URNG>
   result_type operator()(URNG& g);
 template<class URNG>
   result_type operator()(URNG& g, const param_type& parm);

 // property functions
 vector<result_type> intervals() const;
 vector<result_type> densities() const;
 param_type param() const;
 void param(const param_type& parm);
 result_type min() const;
 result_type max() const;
};
```

`piecewise_linear_distribution();`

3 *Effects:* Constructs a `piecewise_linear_distribution` object with $n = 1$, $\rho_0 = \rho_1 = 1$, $b_0 = 0$, and $b_1 = 1$.

```
template<class InputIteratorB, class InputIteratorW>
 piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
                               InputIteratorW firstW);
```

4 *Requires:* `InputIteratorB` and `InputIteratorW` shall each satisfy the requirements of an input iterator (Table 107) type. Moreover, `iterator_traits<InputIteratorB>::value_type` and `iterator_traits<InputIteratorW>::value_type` shall each denote a type that is convertible to `double`. If `firstB == lastB` or `++firstB == lastB`, let $n = 1$, $\rho_0 = \rho_1 = 1$, $b_0 = 0$, and $b_1 = 1$. Otherwise,

$\big[$`firstB`, `lastB`$\big)$ shall form a sequence b of length $n+1$, the length of the sequence w starting from `firstW` shall be at least $n+1$, and any w_k for $k \geq n+1$ shall be ignored by the distribution.

5 *Effects:* Constructs a `piecewise_linear_distribution` object with parameters as specified above.

```
template<class UnaryOperation>
 piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);
```

6 *Requires:* Each instance of type `UnaryOperation` shall be a function object (20.283) whose return type shall be convertible to `double`. Moreover, `double` shall be convertible to the type of `UnaryOperation`'s sole parameter.

7 *Effects:* Constructs a `piecewise_linear_distribution` object with parameters taken or calculated from the following values: If `bl.size()` < 2, let $n = 1$, $\rho_0 = \rho_1 = 1$, $b_0 = 0$, and $b_1 = 1$. Otherwise, let $\big[$`bl.begin()`,`bl.end()`$\big)$ form a sequence $b_0, \ldots, b_n$, and let $w_k =$ `fw`(b_k) for $k = 0, \ldots, n$.

8 *Complexity:* The number of invocations of `fw` shall not exceed $n+1$.

```
template<class UnaryOperation>
 piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
```

9 *Requires:* Each instance of type `UnaryOperation` shall be a function object (20.283) whose return type shall be convertible to `double`. Moreover, `double` shall be convertible to the type of `UnaryOperation`'s sole parameter. If `nw` $= 0$, let $n = 1$, otherwise let $n =$ `nw`. The relation $0 < \delta = (\texttt{xmax} - \texttt{xmin})/n$ shall hold.

10 *Effects:* Constructs a `piecewise_linear_distribution` object with parameters taken or calculated from the following values: Let $b_k = \texttt{xmin} + k \cdot \delta$ for $k = 0, \ldots, n$, and $w_k =$ `fw`(b_k) for $k = 0, \ldots, n$.

11 *Complexity:* The number of invocations of `fw` shall not exceed $n+1$.

```
vector<result_type> intervals() const;
```

12 *Returns:* A `vector<result_type>` whose `size` member returns $n+1$ and whose `operator[]` member returns b_k when invoked with argument k for $k = 0, \ldots, n$.

```
vector<result_type> densities() const;
```

13 *Returns:* A `vector<result_type>` whose `size` member returns n and whose `operator[]` member returns ρ_k when invoked with argument k for $k = 0, \ldots, n$.

}
```

1 The header `<valarray>` defines five class templates (`valarray`, `slice_array`, `gslice_array`, `mask_array`, and `indirect_array`), two classes (`slice` and `gslice`), and a series of related function templates for representing and manipulating arrays of values.

2

The `valarray` array classes are defined to be free of certain forms of aliasing, thus allowing operations on

these classes to be optimized.

1

Any function returning a `valarray<T>` is permitted to return an object of another type, provided all the const member functions of `valarray<T>` are also applicable to this type. This return type shall not add more than two levels of template nesting over the most deeply nested argument type.[280]

1

Implementations introducing such replacement types shall provide additional functions and operators as follows:

— for every function taking a `const valarray<T>&` other than `begin` and `end` (26.142.7), identical functions taking the replacement types shall be added;

— for every function taking two `const valarray<T>&` arguments, identical functions taking every combination of `const valarray<T>&` and replacement types shall be added.

1

In particular, an implementation shall allow a `valarray<T>` to be constructed from such replacement types and shall allow assignments and computed assignments of such types to `valarray<T>`, `slice_array<T>`, `gslice_array<T>`, `mask_array<T>` and `indirect_array<T>` objects.

1 These library functions are permitted to throw a `bad_alloc` (18.223.1.1) exception if there are not sufficient resources available to carry out the operation. Note that the exception is not mandated.

26.134.1 Class template `valarray` [template.valarray]

26.134.1.1 Class template `valarray` overview [template.valarray.overview]

```
namespace std {
  template<class T> class valarray {
  public:
    typedef T value_type;

    // 26.136.0.1 construct/destroy:
    valarray();
    explicit valarray(size_t);
    valarray(const T&, size_t);
    valarray(const T*, size_t);
    valarray(const valarray&);
    valarray(valarray&&) noexcept;
    valarray(const slice_array<T>&);
    valarray(const gslice_array<T>&);
    valarray(const mask_array<T>&);
    valarray(const indirect_array<T>&);
    valarray(initializer_list<T>);
    ~valarray();

    // 26.137.0.1 assignment:
    valarray<T>& operator=(const valarray<T>&);
    valarray<T>& operator=(valarray<T>&&) noexcept;
    valarray& operator=(initializer_list<T>);
    valarray<T>& operator=(const T&);
    valarray<T>& operator=(const slice_array<T>&);
```

280) Clause 18.41.2 recommends a minimum number of recursively nested template instantiations. This requirement thus indirectly suggests a minimum allowable complexity for valarray expressions.

```
valarray<T>& operator=(const gslice_array<T>&);
valarray<T>& operator=(const mask_array<T>&);
valarray<T>& operator=(const indirect_array<T>&);

// 26.139.0.1 element access:
const T&          operator[](size_t) const;
T&                operator[](size_t);

// 26.141.0.1 subset operations:
valarray<T>       operator[](slice) const;
slice_array<T>    operator[](slice);
valarray<T>       operator[](const gslice&) const;
gslice_array<T>   operator[](const gslice&);
valarray<T>       operator[](const valarray<bool>&) const;
mask_array<T>     operator[](const valarray<bool>&);
valarray<T>       operator[](const valarray<size_t>&) const;
indirect_array<T> operator[](const valarray<size_t>&);

// 26.141.0.2 unary operators:
valarray<T> operator+() const;
valarray<T> operator-() const;
valarray<T> operator~() const;
valarray<bool> operator!() const;

// 26.141.0.3 computed assignment:
valarray<T>& operator*= (const T&);
valarray<T>& operator/= (const T&);
valarray<T>& operator%= (const T&);
valarray<T>& operator+= (const T&);
valarray<T>& operator-= (const T&);
valarray<T>& operator^= (const T&);
valarray<T>& operator&= (const T&);
valarray<T>& operator|= (const T&);
valarray<T>& operator<<=(const T&);
valarray<T>& operator>>=(const T&);

valarray<T>& operator*= (const valarray<T>&);
valarray<T>& operator/= (const valarray<T>&);
valarray<T>& operator%= (const valarray<T>&);
valarray<T>& operator+= (const valarray<T>&);
valarray<T>& operator-= (const valarray<T>&);
valarray<T>& operator^= (const valarray<T>&);
valarray<T>& operator|= (const valarray<T>&);
valarray<T>& operator&= (const valarray<T>&);
valarray<T>& operator<<=(const valarray<T>&);
valarray<T>& operator>>=(const valarray<T>&);

// 26.141.0.4 member functions:
void swap(valarray&) noexcept;

size_t size() const;

T sum() const;
T min() const;
T max() const;
```

```
    valarray<T> shift (int) const;
    valarray<T> cshift(int) const;
    valarray<T> apply(T func(T)) const;
    valarray<T> apply(T func(const T&)) const;
    void resize(size_t sz, T c = T());
  };
}
```

1

The class template `valarray<T>` is a one-dimensional smart array, with elements numbered sequentially from zero. It is a representation of the mathematical concept of an ordered set of values. The illusion of higher dimensionality may be produced by the familiar idiom of computed indices, together with the powerful subsetting capabilities provided by the generalized subscript operators.[281]

1 An implementation is permitted to qualify any of the functions declared in `<valarray>` as `inline`.

26.136.0.1 `valarray` constructors [valarray.cons]

`valarray();`

1 *Effects:* Constructs an object of class `valarray<T>`[282] which has zero length.[283]

`explicit valarray(size_t);`

2 The array created by this constructor has a length equal to the value of the argument. The elements of the array are value-initialized (8.821).

`valarray(const T&, size_t);`

3 The array created by this constructor has a length equal to the second argument. The elements of the array are initialized with the value of the first argument.

`valarray(const T*, size_t);`

4

The array created by this constructor has a length equal to the second argument `n`. The values of the elements of the array are initialized with the first `n` values pointed to by the first argument.[284] If the value of the second argument is greater than the number of values pointed to by the first argument, the behavior is undefined.

`valarray(const valarray<T>&);`

1 The array created by this constructor has the same length as the argument array. The elements are initialized with the values of the corresponding elements of the argument array.[285]

`valarray(valarray<T>&& v) noexcept;`

281) The intent is to specify an array template that has the minimum functionality necessary to address aliasing ambiguities and the proliferation of temporaries. Thus, the `valarray` template is neither a matrix class nor a field class. However, it is a very useful building block for designing such classes.
282) For convenience, such objects are referred to as "arrays" throughout the remainder of 26.129.
283) This default constructor is essential, since arrays of `valarray` may be useful. After initialization, the length of an empty array can be increased with the `resize` member function.
284) This constructor is the preferred method for converting a C array to a `valarray` object.
285) This copy constructor creates a distinct array rather than an alias. Implementations in which arrays share storage are permitted, but they shall implement a copy-on-reference mechanism to ensure that arrays are conceptually distinct.

2 The array created by this constructor has the same length as the argument array. The elements are initialized with the values of the corresponding elements of the argument array.

3 *Complexity:* Constant.

```
valarray(initializer_list<T> il);
```

4 *Effects:* Same as `valarray(il.begin(), il.size())`.

```
valarray(const slice_array<T>&);
valarray(const gslice_array<T>&);
valarray(const mask_array<T>&);
valarray(const indirect_array<T>&);
```

5 These conversion constructors convert one of the four reference templates to a `valarray`.

```
~valarray();
```

6 The destructor is applied to every element of `*this`; an implementation may return all allocated memory.

26.137.0.1 `valarray` assignment [valarray.assign]

```
valarray<T>& operator=(const valarray<T>& v);
```

1

Each element of the `*this` array is assigned the value of the corresponding element of the argument array. If the length of `v` is not equal to the length of `*this` , resizes `*this` to make the two arrays the same length, as if by calling `resize(v.size())`, before performing the assignment.

1 *Postcondition:* `size() == v.size()`.

```
valarray<T>& operator=(valarray<T>&& v) noexcept;
```

2 *Effects:* `*this` obtains the value of `v`. The value of `v` after the assignment is not specified.

3 *Complexity:* Linear.

```
valarray& operator=(initializer_list<T> il);
```

4 *Effects:* `*this = valarray(il)`.

5 *Returns:* `*this`.

```
valarray<T>& operator=(const T&);
```

6 The scalar assignment operator causes each element of the `*this` array to be assigned the value of the argument.

```
valarray<T>& operator=(const slice_array<T>&);
valarray<T>& operator=(const gslice_array<T>&);
valarray<T>& operator=(const mask_array<T>&);
valarray<T>& operator=(const indirect_array<T>&);
```

7 *Requires:* The length of the array to which the argument refers equals `size()`.

8 These operators allow the results of a generalized subscripting operation to be assigned directly to a `valarray`.

9 If the value of an element in the left-hand side of a valarray assignment operator depends on the value of another element in that left-hand side, the resulting behavior is undefined.

26.139.0.1 `valarray` element access [valarray.access]

```
const T&  operator[](size_t) const;
T& operator[](size_t);
```

1 The subscript operator returns a reference to the corresponding element of the array.

2 Thus, the expression `(a[i] = q, a[i]) == q` evaluates as true for any non-constant `valarray<T> a`, any `T q`, and for any `size_t i` such that the value of `i` is less than the length of `a`.

3 The expression `&a[i+j] == &a[i] + j` evaluates as true for all `size_t i` and `size_t j` such that `i+j` is less than the length of the array `a`.

1 Likewise, the expression `&a[i] != &b[j]` evaluates as `true` for any two arrays `a` and `b` and for any `size_t i` and `size_t j` such that `i` is less than the length of `a` and `j` is less than the length of `b`. This property indicates an absence of aliasing and may be used to advantage by optimizing compilers.[286]

1 The reference returned by the subscript operator for an array shall be valid until the member function `resize(size_t, T)` (26.141.0.4) is called for that array or until the lifetime of that array ends, whichever happens first.

2 If the subscript operator is invoked with a `size_t` argument whose value is not less than the length of the array, the behavior is undefined.

26.141.0.1 `valarray` subset operations [valarray.sub]

1 The member `operator[]` is overloaded to provide several ways to select sequences of elements from among those controlled by `*this`. Each of these operations returns a subset of the array. The const-qualified versions return this subset as a new `valarray` object. The non-const versions return a class template object which has reference semantics to the original array, working in conjunction with various overloads of `operator=` and other assigning operators to allow selective replacement (slicing) of the controlled sequence. In each case the selected element(s) must exist.

```
valarray<T> operator[](slice slicearr) const;
```

2 *Returns:* An object of class `valarray<T>` containing those elements of the controlled sequence designated by `slicearr`. [*Example:*

```
const valarray<char> v0("abcdefghijklmnop", 16);
// v0[slice(2, 5, 3)] returns valarray<char>("cfilo", 5)
```

— *end example*]

```
slice_array<T> operator[](slice slicearr);
```

3 *Returns:* An object that holds references to elements of the controlled sequence selected by `slicearr`. [*Example:*

```
valarray<char> v0("abcdefghijklmnop", 16);
valarray<char> v1("ABCDE", 5);
v0[slice(2, 5, 3)] = v1;
// v0 == valarray<char>("abAdeBghCjkDmnEp", 16);
```

— *end example*]

286) Compilers may take advantage of inlining, constant propagation, loop fusion, tracking of pointers obtained from `operator new`, and other techniques to generate efficient `valarrays`.

```
valarray<T> operator[](const gslice& gslicearr) const;
```

4 *Returns:* An object of class `valarray<T>` containing those elements of the controlled sequence designated by `gslicearr`. [*Example:*

```
const valarray<char> v0("abcdefghijklmnop", 16);
const size_t lv[] = { 2, 3 };
const size_t dv[] = { 7, 2 };
const valarray<size_t> len(lv, 2), str(dv, 2);
// v0[gslice(3, len, str)] returns
// valarray<char>("dfhkmo", 6)
```

— *end example*]

```
gslice_array<T> operator[](const gslice& gslicearr);
```

5 *Returns:* An object that holds references to elements of the controlled sequence selected by `gslicearr`. [*Example:*

```
valarray<char> v0("abcdefghijklmnop", 16);
valarray<char> v1("ABCDE", 5);
const size_t lv[] = { 2, 3 };
const size_t dv[] = { 7, 2 };
const valarray<size_t> len(lv, 2), str(dv, 2);
v0[gslice(3, len, str)] = v1;
// v0 == valarray<char>("abcAeBgCijDlEnFp", 16)
```

— *end example*]

```
valarray<T> operator[](const valarray<bool>& boolarr) const;
```

6 *Returns:* An object of class `valarray<T>` containing those elements of the controlled sequence designated by `boolarr`. [*Example:*

```
const valarray<char> v0("abcdefghijklmnop", 16);
const bool vb[] = { false, false, true, true, false, true };
// v0[valarray<bool>(vb, 6)] returns
// valarray<char>("cdf", 3)
```

— *end example*]

```
mask_array<T> operator[](const valarray<bool>& boolarr);
```

7 *Returns:* An object that holds references to elements of the controlled sequence selected by `boolarr`. [*Example:*

```
valarray<char> v0("abcdefghijklmnop", 16);
valarray<char> v1("ABC", 3);
const bool vb[] = { false, false, true, true, false, true };
v0[valarray<bool>(vb, 6)] = v1;
// v0 == valarray<char>("abABeCghijklmnop", 16)
```

— *end example*]

```
valarray<T> operator[](const valarray<size_t>& indarr) const;
```

8 *Returns:* An object of class `valarray<T>` containing those elements of the controlled sequence designated by `indarr`. [*Example:*

```
const valarray<char> v0("abcdefghijklmnop", 16);
const size_t vi[] = { 7, 5, 2, 3, 8 };
// v0[valarray<size_t>(vi, 5)] returns
// valarray<char>("hfcdi", 5)
```

— *end example*]

```
indirect_array<T> operator[](const valarray<size_t>& indarr);
```

9 *Returns:* An object that holds references to elements of the controlled sequence selected by `indarr`. [*Example:*

```
valarray<char> v0("abcdefghijklmnop", 16);
valarray<char> v1("ABCDE", 5);
const size_t vi[] = { 7, 5, 2, 3, 8 };
v0[valarray<size_t>(vi, 5)] = v1;
// v0 == valarray<char>("abCDeBgAEjklmnop", 16)
```

— *end example*]

26.141.0.2 `valarray` unary operators [valarray.unary]

```
valarray<T> operator+() const;
valarray<T> operator-() const;
valarray<T> operator~() const;
valarray<bool> operator!() const;
```

1 Each of these operators may only be instantiated for a type `T` to which the indicated operator can be applied and for which the indicated operator returns a value which is of type `T` (`bool` for `operator!`) or which may be unambiguously implicitly converted to type `T` (`bool` for `operator!`).

2 Each of these operators returns an array whose length is equal to the length of the array. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array.

26.141.0.3 `valarray` computed assignment [valarray.cassign]

```
valarray<T>& operator*= (const valarray<T>&);
valarray<T>& operator/= (const valarray<T>&);
valarray<T>& operator%= (const valarray<T>&);
valarray<T>& operator+= (const valarray<T>&);
valarray<T>& operator-= (const valarray<T>&);
valarray<T>& operator^= (const valarray<T>&);
valarray<T>& operator&= (const valarray<T>&);
valarray<T>& operator|= (const valarray<T>&);
valarray<T>& operator<<=(const valarray<T>&);
valarray<T>& operator>>=(const valarray<T>&);
```

1 Each of these operators may only be instantiated for a type `T` to which the indicated operator can be applied. Each of these operators performs the indicated operation on each of its elements and the corresponding element of the argument array.

2 The array is then returned by reference.

3 If the array and the argument array do not have the same length, the behavior is undefined. The appearance of an array on the left-hand side of a computed assignment does `not` invalidate references or pointers.

4 If the value of an element in the left-hand side of a valarray computed assignment operator depends on the value of another element in that left hand side, the resulting behavior is undefined.

```
valarray<T>& operator*= (const T&);
valarray<T>& operator/= (const T&);
valarray<T>& operator%= (const T&);
valarray<T>& operator+= (const T&);
valarray<T>& operator-= (const T&);
valarray<T>& operator^= (const T&);
valarray<T>& operator&= (const T&);
valarray<T>& operator|= (const T&);
valarray<T>& operator<<=(const T&);
valarray<T>& operator>>=(const T&);
```

5 Each of these operators may only be instantiated for a type `T` to which the indicated operator can be applied.

6 Each of these operators applies the indicated operation to each element of the array and the non-array argument.

7 The array is then returned by reference.

8 The appearance of an array on the left-hand side of a computed assignment does *not* invalidate references or pointers to the elements of the array.

26.141.0.4 `valarray` member functions [valarray.members]

```
void swap(valarray& v) noexcept;
```

1 *Effects:* `*this` obtains the value of `v`. `v` obtains the value of `*this`.

2 *Complexity:* Constant.

```
size_t size() const;
```

3 *Returns:* The number of elements in the array.

4 *Complexity:* Constant time.

```
T sum() const;
```

This function may only be instantiated for a type `T` to which `operator+=` can be applied. This function returns the sum of all the elements of the array.

5 If the array has length 0, the behavior is undefined. If the array has length 1, `sum()` returns the value of element 0. Otherwise, the returned value is calculated by applying `operator+=` to a copy of an element of the array and all other elements of the array in an unspecified order.

```
T min() const;
```

6 This function returns the minimum value contained in `*this`. The value returned for an array of length 0 is undefined. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using `operator<`.

```
T max() const;
```

7 This function returns the maximum value contained in `*this`. The value returned for an array of length 0 is undefined. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using `operator<`.

```
valarray<T> shift(int n) const;
```

8 This function returns an object of class `valarray<T>` of length `size()`, each of whose elements I is `(*this)[I + n]` if `I + n` is non-negative and less than `size()`, otherwise `T()`. Thus if element zero is taken as the leftmost element, a positive value of `n` shifts the elements left `n` places, with zero fill.

9 [*Example:* If the argument has the value -2, the first two elements of the result will be value-initialized (8.821); the third element of the result will be assigned the value of the first element of the argument; etc. — *end example*]

```
valarray<T> cshift(int n) const;
```

10 This function returns an object of class `valarray<T>` of length `size()` that is a circular shift of `*this`. If element zero is taken as the leftmost element, a non-negative value of n shifts the elements circularly left n places and a negative value of n shifts the elements circularly right -n places.

```
valarray<T> apply(T func(T)) const;
valarray<T> apply(T func(const T&)) const;
```

11 These functions return an array whose length is equal to the array. Each element of the returned array is assigned the value returned by applying the argument function to the corresponding element of the array.

```
void resize(size_t sz, T c = T());
```

12 This member function changes the length of the `*this` array to `sz` and then assigns to each element the value of the second argument. Resizing invalidates all pointers and references to elements in the array.

26.141.1 `valarray` non-member operations [valarray.nonmembers]

26.141.1.1 `valarray` binary operators [valarray.binary]

```
template<class T> valarray<T> operator*
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator/
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator%
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator+
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator-
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator^
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator&
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator|
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator<<
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator>>
    (const valarray<T>&, const valarray<T>&);
```

1 Each of these operators may only be instantiated for a type `T` to which the indicated operator can be applied and for which the indicated operator returns a value which is of type `T` or which can be unambiguously implicitly converted to type `T`.

2 Each of these operators returns an array whose length is equal to the lengths of the argument arrays. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.

3 If the argument arrays do not have the same length, the behavior is undefined.

```
template<class T> valarray<T> operator* (const valarray<T>&, const T&);
template<class T> valarray<T> operator* (const T&, const valarray<T>&);
template<class T> valarray<T> operator/ (const valarray<T>&, const T&);
template<class T> valarray<T> operator/ (const T&, const valarray<T>&);
template<class T> valarray<T> operator% (const valarray<T>&, const T&);
template<class T> valarray<T> operator% (const T&, const valarray<T>&);
template<class T> valarray<T> operator+ (const valarray<T>&, const T&);
template<class T> valarray<T> operator+ (const T&, const valarray<T>&);
template<class T> valarray<T> operator- (const valarray<T>&, const T&);
template<class T> valarray<T> operator- (const T&, const valarray<T>&);
template<class T> valarray<T> operator^ (const valarray<T>&, const T&);
template<class T> valarray<T> operator^ (const T&, const valarray<T>&);
template<class T> valarray<T> operator& (const valarray<T>&, const T&);
template<class T> valarray<T> operator& (const T&, const valarray<T>&);
template<class T> valarray<T> operator| (const valarray<T>&, const T&);
template<class T> valarray<T> operator| (const T&, const valarray<T>&);
template<class T> valarray<T> operator<<(const valarray<T>&, const T&);
template<class T> valarray<T> operator<<(const T&, const valarray<T>&);
template<class T> valarray<T> operator>>(const valarray<T>&, const T&);
template<class T> valarray<T> operator>>(const T&, const valarray<T>&);
```

4 Each of these operators may only be instantiated for a type `T` to which the indicated operator can be applied and for which the indicated operator returns a value which is of type `T` or which can be unambiguously implicitly converted to type `T`.

5 Each of these operators returns an array whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array argument and the non-array argument.

26.141.1.2 `valarray` logical operators [valarray.comparison]

```
template<class T> valarray<bool> operator==
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator!=
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator<
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator>
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator<=
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator>=
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator&&
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator||
    (const valarray<T>&, const valarray<T>&);
```

1 Each of these operators may only be instantiated for a type `T` to which the indicated operator can be applied and for which the indicated operator returns a value which is of type `bool` or which can be unambiguously implicitly converted to type `bool`.

2 Each of these operators returns a `bool` array whose length is equal to the length of the array arguments. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.

3 If the two array arguments do not have the same length, the behavior is undefined.

```
template<class T> valarray<bool> operator==(const valarray<T>&, const T&);
template<class T> valarray<bool> operator==(const T&, const valarray<T>&);
template<class T> valarray<bool> operator!=(const valarray<T>&, const T&);
template<class T> valarray<bool> operator!=(const T&, const valarray<T>&);
template<class T> valarray<bool> operator< (const valarray<T>&, const T&);
template<class T> valarray<bool> operator< (const T&, const valarray<T>&);
template<class T> valarray<bool> operator> (const valarray<T>&, const T&);
template<class T> valarray<bool> operator> (const T&, const valarray<T>&);
template<class T> valarray<bool> operator<=(const valarray<T>&, const T&);
template<class T> valarray<bool> operator<=(const T&, const valarray<T>&);
template<class T> valarray<bool> operator>=(const valarray<T>&, const T&);
template<class T> valarray<bool> operator>=(const T&, const valarray<T>&);
template<class T> valarray<bool> operator&&(const valarray<T>&, const T&);
template<class T> valarray<bool> operator&&(const T&, const valarray<T>&);
template<class T> valarray<bool> operator||(const valarray<T>&, const T&);
template<class T> valarray<bool> operator||(const T&, const valarray<T>&);
```

4 Each of these operators may only be instantiated for a type `T` to which the indicated operator can be applied and for which the indicated operator returns a value which is of type `bool` or which can be unambiguously implicitly converted to type `bool`.

5 Each of these operators returns a `bool` array whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array and the non-array argument.

26.141.1.3 `valarray` transcendentals [valarray.transcend]

```
template<class T> valarray<T> abs  (const valarray<T>&);
template<class T> valarray<T> acos (const valarray<T>&);
template<class T> valarray<T> asin (const valarray<T>&);
template<class T> valarray<T> atan (const valarray<T>&);
template<class T> valarray<T> atan2
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const T&);
template<class T> valarray<T> atan2(const T&, const valarray<T>&);
template<class T> valarray<T> cos  (const valarray<T>&);
template<class T> valarray<T> cosh (const valarray<T>&);
template<class T> valarray<T> exp  (const valarray<T>&);
template<class T> valarray<T> log  (const valarray<T>&);
template<class T> valarray<T> log10(const valarray<T>&);
template<class T> valarray<T> pow
    (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> pow  (const valarray<T>&, const T&);
template<class T> valarray<T> pow  (const T&, const valarray<T>&);
template<class T> valarray<T> sin  (const valarray<T>&);
template<class T> valarray<T> sinh (const valarray<T>&);
template<class T> valarray<T> sqrt (const valarray<T>&);
template<class T> valarray<T> tan  (const valarray<T>&);
template<class T> valarray<T> tanh (const valarray<T>&);
```

1

Each of these functions may only be instantiated for a type `T` to which a unique function with the indicated name can be applied (unqualified). This function shall return a value which is of type `T` or which can be unambiguously implicitly converted to type `T`.

26.142.0.1 `valarray` specialized algorithms [valarray.special]

```
template <class T> void swap(valarray<T>& x, valarray<T>& y) noexcept;
```

1 *Effects:* `x.swap(y)`.

26.142.1 Class `slice` [class.slice]

26.142.1.1 Class `slice` overview [class.slice.overview]

```
namespace std {
  class slice {
  public:
    slice();
    slice(size_t, size_t, size_t);

    size_t start() const;
    size_t size() const;
    size_t stride() const;
  };
}
```

1 The `slice` class represents a BLAS-like slice from an array. Such a slice is specified by a starting index, a length, and a stride.[287]

26.142.1.2 `slice` constructors [cons.slice]

```
slice();
slice(size_t start, size_t length, size_t stride);
slice(const slice&);
```

1 The default constructor is equivalent to `slice(0, 0, 0)`. A default constructor is provided only to permit the declaration of arrays of slices. The constructor with arguments for a slice takes a start, length, and stride parameter.

2 [*Example:* `slice(3, 8, 2)` constructs a slice which selects elements 3, 5, 7, ... 17 from an array. — *end example*]

26.142.1.3 `slice` access functions [slice.access]

```
size_t start() const;
size_t size() const;
size_t stride() const;
```

1 *Returns:* The start, length, or stride specified by a `slice` object.

2 *Complexity:* Constant time.

26.142.2 Class template `slice_array` [template.slice.array]

26.142.2.1 Class template `slice_array` overview [template.slice.array.overview]

```
namespace std {
  template <class T> class slice_array {
  public:
    typedef T value_type;

    void operator=  (const valarray<T>&) const;
```

287) BLAS stands for *Basic Linear Algebra Subprograms.* C++ programs may instantiate this class. See, for example, Dongarra, Du Croz, Duff, and Hammerling: *A set of Level 3 Basic Linear Algebra Subprograms*; Technical Report MCS-P1-0888, Argonne National Laboratory (USA), Mathematics and Computer Science Division, August, 1988.

```
    void operator*= (const valarray<T>&) const;
    void operator/= (const valarray<T>&) const;
    void operator%= (const valarray<T>&) const;
    void operator+= (const valarray<T>&) const;
    void operator-= (const valarray<T>&) const;
    void operator^= (const valarray<T>&) const;
    void operator&= (const valarray<T>&) const;
    void operator|= (const valarray<T>&) const;
    void operator<<=(const valarray<T>&) const;
    void operator>>=(const valarray<T>&) const;

    slice_array(const slice_array&);
    ~slice_array();
    const slice_array& operator=(const slice_array&) const;
  void operator=(const T&) const;

    slice_array() = delete;        // as implied by declaring copy constructor above
  };
}
```

1 The `slice_array` template is a helper template used by the `slice` subscript operator

```
slice_array<T> valarray<T>::operator[](slice);
```

It has reference semantics to a subset of an array specified by a `slice` object.

2 [*Example:* The expression `a[slice(1, 5, 3)] = b;` has the effect of assigning the elements of `b` to a slice of the elements in `a`. For the slice shown, the elements selected from `a` are 1, 4, ..., 13. — *end example*]

26.142.2.2 `slice_array` assignment [slice.arr.assign]

```
void operator=(const valarray<T>&) const;
const slice_array& operator=(const slice_array&) const;
```

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which the `slice_array` object refers.

26.142.2.3 `slice_array` computed assignment [slice.arr.comp.assign]

```
void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;
```

1 These computed assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `slice_array` object refers.

26.142.2.4 `slice_array` fill function [slice.arr.fill]

```
void operator=(const T&) const;
```

1 This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `slice_array` object refers.

26.142.3 The `gslice` class [class.gslice]

26.142.3.1 The `gslice` class overview [class.gslice.overview]

```
namespace std {
  class gslice {
  public:
    gslice();
    gslice(size_t s, const valarray<size_t>& l, const valarray<size_t>& d);

    size_t           start() const;
    valarray<size_t> size() const;
    valarray<size_t> stride() const;
  };
}
```

1 This class represents a generalized slice out of an array. A `gslice` is defined by a starting offset (s), a set of lengths (l_j), and a set of strides (d_j). The number of lengths shall equal the number of strides.

2 A `gslice` represents a mapping from a set of indices (i_j), equal in number to the number of strides, to a single index k. It is useful for building multidimensional array classes using the `valarray` template, which is one-dimensional. The set of one-dimensional index values specified by a `gslice` are

$$k = s + \sum_j i_j d_j$$

where the multidimensional indices i_j range in value from 0 to $l_{ij} - 1$.

3 [*Example:* The `gslice` specification

```
start  = 3
length = {2, 4, 3}
stride = {19, 4, 1}
```

yields the sequence of one-dimensional indices

$$k = 3 + (0,1) \times 19 + (0,1,2,3) \times 4 + (0,1,2) \times 1$$

which are ordered as shown in the following table:

$(i_0,$	$i_1,$	$i_2,$	$k)$	$=$
	(0,	0,	0,	3),
	(0,	0,	1,	4),
	(0,	0,	2,	5),
	(0,	1,	0,	7),
	(0,	1,	1,	8),
	(0,	1,	2,	9),
	(0,	2,	0,	11),
	(0,	2,	1,	12),
	(0,	2,	2,	13),
	(0,	3,	0,	15),
	(0,	3,	1,	16),
	(0,	3,	2,	17),

(1, 0, 0, 22),
(1, 0, 1, 23),
...
(1, 3, 2, 36)

That is, the highest-ordered index turns fastest. — *end example*]

4 It is possible to have degenerate generalized slices in which an address is repeated.

5 [*Example:* If the stride parameters in the previous example are changed to {1, 1, 1}, the first few elements of the resulting sequence of indices will be

(0, 0, 0, 3),
(0, 0, 1, 4),
(0, 0, 2, 5),
(0, 1, 0, 4),
(0, 1, 1, 5),
(0, 1, 2, 6),
...

— *end example*]

6 If a degenerate slice is used as the argument to the non-`const` version of `operator[](const gslice&)`, the resulting behavior is undefined.

26.142.3.2 `gslice` constructors [gslice.cons]

```
gslice();
gslice(size_t start, const valarray<size_t>& lengths,
         const valarray<size_t>& strides);
gslice(const gslice&);
```

1 The default constructor is equivalent to `gslice(0, valarray<size_t>(), valarray<size_t>())`. The constructor with arguments builds a `gslice` based on a specification of start, lengths, and strides, as explained in the previous section.

26.142.3.3 `gslice` access functions [gslice.access]

```
size_t           start()  const;
valarray<size_t> size() const;
valarray<size_t> stride() const;
```

1 *Returns:* The representation of the start, lengths, or strides specified for the `gslice`.

2 *Complexity:* `start()` is constant time. `size()` and `stride()` are linear in the number of strides.

26.142.4 Class template `gslice_array` [template.gslice.array]

26.142.4.1 Class template `gslice_array` overview [template.gslice.array.overview]

```
namespace std {
  template <class T> class gslice_array {
  public:
    typedef T value_type;

    void operator=  (const valarray<T>&) const;
    void operator*= (const valarray<T>&) const;
    void operator/= (const valarray<T>&) const;
    void operator%= (const valarray<T>&) const;
    void operator+= (const valarray<T>&) const;
```

```
    void operator-= (const valarray<T>&) const;
    void operator^= (const valarray<T>&) const;
    void operator&= (const valarray<T>&) const;
    void operator|= (const valarray<T>&) const;
    void operator<<=(const valarray<T>&) const;
    void operator>>=(const valarray<T>&) const;

    gslice_array(const gslice_array&);
    ~gslice_array();
    const gslice_array& operator=(const gslice_array&) const;
    void operator=(const T&) const;

    gslice_array() = delete;       // as implied by declaring copy constructor above
  };
}
```

1 This template is a helper template used by the `slice` subscript operator

```
gslice_array<T> valarray<T>::operator[](const gslice&);
```

2 It has reference semantics to a subset of an array specified by a `gslice` object.

3 Thus, the expression `a[gslice(1, length, stride)] = b` has the effect of assigning the elements of `b` to a generalized slice of the elements in `a`.

26.142.4.2 `gslice_array` assignment [gslice.array.assign]

```
void operator=(const valarray<T>&) const;
const gslice_array& operator=(const gslice_array&) const;
```

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which the `gslice_array` refers.

26.142.4.3 `gslice_array` [gslice.array.comp.assign]

```
void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;
```

1 These computed assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `gslice_array` object refers.

26.142.4.4 `gslice_array` fill function [gslice.array.fill]

```
void operator=(const T&) const;
```

1 This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `gslice_array` object refers.

26.142.5 Class template `mask_array` [template.mask.array]

26.142.5.1 Class template `mask_array` overview [template.mask.array.overview]

```
namespace std {
  template <class T> class mask_array {
  public:
    typedef T value_type;

    void operator=  (const valarray<T>&) const;
    void operator*= (const valarray<T>&) const;
    void operator/= (const valarray<T>&) const;
    void operator%= (const valarray<T>&) const;
    void operator+= (const valarray<T>&) const;
    void operator-= (const valarray<T>&) const;
    void operator^= (const valarray<T>&) const;
    void operator&= (const valarray<T>&) const;
    void operator|= (const valarray<T>&) const;
    void operator<<=(const valarray<T>&) const;
    void operator>>=(const valarray<T>&) const;

    mask_array(const mask_array&);
   ~mask_array();
    const mask_array& operator=(const mask_array&) const;
    void operator=(const T&) const;

    mask_array() = delete;        // as implied by declaring copy constructor above
  };
}
```

1 This template is a helper template used by the mask subscript operator:

`mask_array<T> valarray<T>::operator[](const valarray<bool>&).`

2 It has reference semantics to a subset of an array specified by a boolean mask. Thus, the expression `a[mask] = b;` has the effect of assigning the elements of `b` to the masked elements in `a` (those for which the corresponding element in `mask` is `true`.)

26.142.5.2 `mask_array` assignment [mask.array.assign]

```
void operator=(const valarray<T>&) const;
const mask_array& operator=(const mask_array&) const;
```

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which it refers.

26.142.5.3 `mask_array` computed assignment [mask.array.comp.assign]

```
void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;
```

1 These computed assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the mask object refers.

26.142.5.4 `mask_array` fill function [mask.array.fill]

```
void operator=(const T&) const;
```

1 This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `mask_array` object refers.

26.142.6 Class template `indirect_array` [template.indirect.array]

26.142.6.1 Class template `indirect_array` overview [template.indirect.array.overview]

```
namespace std {
  template <class T> class indirect_array {
  public:
    typedef T value_type;

    void operator=  (const valarray<T>&) const;
    void operator*= (const valarray<T>&) const;
    void operator/= (const valarray<T>&) const;
    void operator%= (const valarray<T>&) const;
    void operator+= (const valarray<T>&) const;
    void operator-= (const valarray<T>&) const;
    void operator^= (const valarray<T>&) const;
    void operator&= (const valarray<T>&) const;
    void operator|= (const valarray<T>&) const;
    void operator<<=(const valarray<T>&) const;
    void operator>>=(const valarray<T>&) const;

    indirect_array(const indirect_array&);
   ~indirect_array();
    const indirect_array& operator=(const indirect_array&) const;
    void operator=(const T&) const;

    indirect_array() = delete;        // as implied by declaring copy constructor above
  };
}
```

1 This template is a helper template used by the indirect subscript operator

`indirect_array<T> valarray<T>::operator[](const valarray<size_t>&).`

2 It has reference semantics to a subset of an array specified by an `indirect_array`. Thus the expression `a[indirect] = b;` has the effect of assigning the elements of `b` to the elements in `a` whose indices appear in `indirect`.

26.142.6.2 `indirect_array` assignment [indirect.array.assign]

```
void operator=(const valarray<T>&) const;
const indirect_array& operator=(const indirect_array&) const;
```

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which it refers.

2 If the `indirect_array` specifies an element in the `valarray<T>` object to which it refers more than once, the behavior is undefined.

3 [*Example:*

```
int addr[] = {2, 3, 1, 4, 4};
valarray<size_t> indirect(addr, 5);
```

```
valarray<double> a(0., 10), b(1., 5);
a[indirect] = b;
```

results in undefined behavior since element 4 is specified twice in the indirection. — *end example*]

26.142.6.3 `indirect_array` computed assignment [indirect.array.comp.assign]

```
void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;
```

1 These computed assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `indirect_array` object refers.

2 If the `indirect_array` specifies an element in the `valarray<T>` object to which it refers more than once, the behavior is undefined.

26.142.6.4 `indirect_array` fill function [indirect.array.fill]

```
void operator=(const T&) const;
```

1 This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `indirect_array` object refers.

26.142.7 valarray range access [valarray.range]

1

In the `begin` and `end` function templates that follow, *`unspecified`*1 is a type that meets the requirements of a mutable random access iterator (24.167.1) whose `value_type` is the template parameter `T` and whose `reference` type is `T&`. *`unspecified`*2 is a type that meets the requirements of a constant random access iterator (24.167.1) whose `value_type` is the template parameter `T` and whose `reference` type is `const T&`.

1 The iterators returned by `begin` and `end` for an array are guaranteed to be valid until the member function `resize(size_t, T)` (26.141.0.4) is called for that array or until the lifetime of that array ends, whichever happens first.

```
template <class T> unspecified1 begin(valarray<T>& v);
template <class T> unspecified2 begin(const valarray<T>& v);
```

2 *Returns:* An iterator referencing the first value in the numeric array.

```
template <class T> unspecified1 end(valarray<T>& v);
template <class T> unspecified2 end(const valarray<T>& v);
```

3 *Returns:* An iterator referencing one past the last value in the numeric array.

26.144 Generalized numeric operations [numeric.ops]

26.144.1 Header `<numeric>` synopsis [numeric.ops.overview]

```
namespace std {
  template <class InputIterator, class T>
    T accumulate(InputIterator first, InputIterator last, T init);
  template <class InputIterator, class T, class BinaryOperation>
    T accumulate(InputIterator first, InputIterator last, T init,
                 BinaryOperation binary_op);

  template <class InputIterator1, class InputIterator2, class T>
    T inner_product(InputIterator1 first1, InputIterator1 last1,
                    InputIterator2 first2, T init);
  template <class InputIterator1, class InputIterator2, class T,
            class BinaryOperation1, class BinaryOperation2>
    T inner_product(InputIterator1 first1, InputIterator1 last1,
                    InputIterator2 first2, T init,
                    BinaryOperation1 binary_op1,
                    BinaryOperation2 binary_op2);

  template <class InputIterator, class OutputIterator>
    OutputIterator partial_sum(InputIterator first,
                               InputIterator last,
                               OutputIterator result);
  template <class InputIterator, class OutputIterator,
            class BinaryOperation>
    OutputIterator partial_sum(InputIterator first,
                               InputIterator last,
                               OutputIterator result,
                               BinaryOperation binary_op);

  template <class InputIterator, class OutputIterator>
    OutputIterator adjacent_difference(InputIterator first,
                                       InputIterator last,
                                       OutputIterator result);
  template <class InputIterator, class OutputIterator,
            class BinaryOperation>
    OutputIterator adjacent_difference(InputIterator first,
                                       InputIterator last,
                                       OutputIterator result,
                                       BinaryOperation binary_op);

  template <class ForwardIterator, class T>
    void iota(ForwardIterator first, ForwardIterator last, T value);
}
```

1 The requirements on the types of algorithms' arguments that are described in the introduction to Clause 25 also apply to the following algorithms.

26.144.2 Accumulate [accumulate]

```
template <class InputIterator, class T>
  T accumulate(InputIterator first, InputIterator last, T init);
template <class InputIterator, class T, class BinaryOperation>
  T accumulate(InputIterator first, InputIterator last, T init,
               BinaryOperation binary_op);
```

1

Effects: Computes its result by initializing the accumulator `acc` with the initial value `init` and then

modifies it with `acc = acc + *i` or `acc = binary_op(acc, *i)` for every iterator `i` in the range `[first,last)` in order.[288]

1

Requires: `T` shall meet the requirements of `CopyConstructible` (Table 21) and `CopyAssignable` (Table 23) types. In the range `[first,last]`, `binary_op` shall neither modify elements nor invalidate iterators or subranges.[289]

26.147.1 Inner product [inner.product]

```
template <class InputIterator1, class InputIterator2, class T>
  T inner_product(InputIterator1 first1, InputIterator1 last1,
                  InputIterator2 first2, T init);
template <class InputIterator1, class InputIterator2, class T,
    class BinaryOperation1, class BinaryOperation2>
  T inner_product(InputIterator1 first1, InputIterator1 last1,
                  InputIterator2 first2, T init,
                  BinaryOperation1 binary_op1,
                  BinaryOperation2 binary_op2);
```

1 *Effects:* Computes its result by initializing the accumulator `acc` with the initial value `init` and then modifying it with `acc = acc + (*i1) * (*i2)` or `acc = binary_op1(acc, binary_op2(*i1, *i2))` for every iterator `i1` in the range `[first1,last1)` and iterator `i2` in the range `[first2,first2 + (last1 - first1))` in order.

2 *Requires:* `T` shall meet the requirements of `CopyConstructible` (Table 21) and `CopyAssignable` (Table 23) types. In the ranges `[first1,last1]` and `[first2,first2 + (last1 - first1)]` `binary_op1` and `binary_op2` shall neither modify elements nor invalidate iterators or subranges.[290]

26.147.2 Partial sum [partial.sum]

```
template <class InputIterator, class OutputIterator>
  OutputIterator partial_sum(
    InputIterator first, InputIterator last,
    OutputIterator result);
template
  <class InputIterator, class OutputIterator, class BinaryOperation>
    OutputIterator partial_sum(
      InputIterator first, InputIterator last,
      OutputIterator result, BinaryOperation binary_op);
```

1

Effects: For a non-empty range, the function creates an accumulator `acc` whose type is `InputIterator`'s value type, initializes it with `*first`, and assigns the result to `*result`. For every iterator `i` in `[first + 1,last)` in order, `acc` is then modified by `acc = acc + *i` or `acc = binary_op(acc, *i)` and the result is assigned to `*(result + (i - first))`.

1 *Returns:* `result + (last - first)`.

2 *Complexity:* Exactly `(last - first) - 1` applications of the binary operation.

3 *Requires:* `InputIterator`'s value type shall be constructible from the type of `*first`. The result of the expression `acc + *i` or `binary_op(acc, *i)` shall be implicitly convertible to `InputIterator`'s

288) `accumulate` is similar to the APL reduction operator and Common Lisp reduce function, but it avoids the difficulty of defining the result of reduction on an empty sequence by always requiring an initial value.
289) The use of fully closed ranges is intentional
290) The use of fully closed ranges is intentional

value type. `acc` shall be writable to the `result` output iterator. In the ranges `[first,last]` and `[result,result + (last - first)]` `binary_op` shall neither modify elements nor invalidate iterators or subranges.[291]

4 *Remarks:* `result` may be equal to `first`.

26.148.1 Adjacent difference [adjacent.difference]

```
template <class InputIterator, class OutputIterator>
  OutputIterator adjacent_difference(
    InputIterator first, InputIterator last,
    OutputIterator result);
template <class InputIterator, class OutputIterator, class BinaryOperation>
  OutputIterator adjacent_difference(
    InputIterator first, InputIterator last,
    OutputIterator result,
    BinaryOperation binary_op);
```

1 *Effects:* For a non-empty range, the function creates an accumulator `acc` whose type is `InputIterator`'s value type, initializes it with `*first`, and assigns the result to `*result`. For every iterator `i` in `[first + 1,last)` in order, creates an object `val` whose type is `InputIterator`'s value type, initializes it with `*i`, computes `val - acc` or `binary_op(val, acc)`, assigns the result to `*(result + (i - first))`, and move assigns from `val` to `acc`.

2 *Requires:* `InputIterator`'s value type shall be `MoveAssignable` (Table 22) and shall be constructible from the type of `*first`. `acc` shall be writable to the `result` output iterator. The result of the expression `val - acc` or `binary_op(val, acc)` shall be writable to the `result` output iterator. In the ranges `[first,last]` and `[result,result + (last - first)]`, `binary_op` shall neither modify elements nor invalidate iterators or subranges.[292]

3 *Remarks:* `result` may be equal to `first`.

4 *Returns:* `result + (last - first)`.

5 *Complexity:* Exactly `(last - first) - 1` applications of the binary operation.

26.148.2 Iota [numeric.iota]

```
template <class ForwardIterator, class T>
  void iota(ForwardIterator first, ForwardIterator last, T value);
```

1 *Requires:* `T` shall be convertible to `ForwardIterator`'s value type. The expression `++val`, where `val` has type `T`, shall be well formed.

2 *Effects:* For each element referred to by the iterator `i` in the range `[first,last)`, assigns `*i = value` and increments `value` as if by `++value`.

3 *Complexity:* Exactly `last - first` increments and assignments.

26.149 C library [c.math]

1 The header `<ctgmath>` simply includes the headers `<ccomplex>` and `<cmath>`.

2 [*Note:* The overloads provided in C by type-generic macros are already provided in `<ccomplex>` and `<cmath>` by "sufficient" additional overloads. — *end note*]

3 Tables 119 and 120 describe headers `<cmath>` and `<cstdlib>`, respectively.

4

291) The use of fully closed ranges is intentional.
292) The use of fully closed ranges is intentional.

Table 119 — Header `<cmath>` synopsis

Type	Name(s)			
Macros:				
FP_FAST_FMA	FP_ILOGBNAN	FP_SUBNORMAL	HUGE_VALL	MATH_ERRNO
FP_FAST_FMAF	FP_INFINITE	FP_ZERO	INFINITY	MATH_ERREXCEPT
FP_FAST_FMAL	FP_NAN	HUGE_VAL	NAN	math_errhandling
FP_ILOGB0	FP_NORMAL	HUGE_VALF		
Types:	double_t	float_t		
Math Functions:				
abs	cosh	fmod	logb	remquo
acos	erf	frexp	lrint	rint
acosh	erfc	hypot	lround	round
asin	exp2	ilogb	modf	scalbln
asinh	exp	ldexp	nan	scalbn
atan	expm1	lgamma	nanf	sin
atan2	fabs	llrint	nanl	sinh
atanh	fdim	llround	nearbyint	sqrt
cbrt	floor	log	nextafter	tan
ceil	fma	log10	nexttoward	tanh
copysign	fmax	log1p	pow	tgamma
cos	fmin	log2	remainder	trunc
Classification/comparison Functions:				
fpclassify	isgreaterequal	islessequal	isnan	isunordered
isfinite	isinf	islessgreater	isnormal	signbit
isgreater	isless			

Table 120 — Header `<cstdlib>` synopsis

Type	Name(s)	
Macro:	RAND_MAX	
Types:		
div_t	ldiv_t	lldiv_t
Functions:		
abs	ldiv	rand
div	llabs	srand
labs	lldiv	

The contents of these headers are the same as the Standard C library headers `<math.h>` and `<stdlib.h>` respectively, with the following changes:

1

The `rand` function has the semantics specified in the C standard, except that the implementation may specify that particular library functions may call `rand`. It is implementation-defined whether the `rand` function may introduce data races (17.607.0.1). [*Note:* The random number generation (26.45) facilities in this standard are often preferable to `rand`, because `rand`'s underlying algorithm is unspecified. Use of `rand` therefore continues to be nonportable, with unpredictable and oft-questionable quality and performance. — *end note*]

1

In addition to the `int` versions of certain math functions in `<cstdlib>`, C++ adds `long` and `long long` overloaded versions of these functions, with the same semantics.

1 The added signatures are:

```
long abs(long);                     // labs()
long long abs(long long);           // llabs()
ldiv_t div(long, long);             // ldiv()
lldiv_t div(long long, long long);  // lldiv()
```

2

In addition to the `double` versions of the math functions in `<cmath>`, C++ adds `float` and `long double` overloaded versions of these functions, with the same semantics.

1 The added signatures are:

```
float abs(float);
float acos(float);
float acosh(float);
float asin(float);
float asinh(float);
float atan(float);
float atan2(float, float);
float atanh(float);
float cbrt(float);
float ceil(float);
float copysign(float, float);
float cos(float);
float cosh(float);
float erf(float);
float erfc(float);
float exp(float);
float exp2(float);
float expm1(float);
float fabs(float);
float fdim(float, float);
float floor(float);
float fma(float, float, float);
float fmax(float, float);
float fmin(float, float);
float fmod(float, float);
float frexp(float, int*);
float hypot(float, float);
int ilogb(float);
```

```
float ldexp(float, int);
float lgamma(float);
long long llrint(float);
long long llround(float);
float log(float);
float log10(float);
float log1p(float);
float log2(float);
float logb(float);
long lrint(float);
long lround(float);
float modf(float, float*);
float nearbyint(float);

```

2

The classification/comparison functions behave the same as the C macros with the corresponding names defined in 7.12.3, Classification macros, and 7.12.14, Comparison macros in the C Standard. Each function is overloaded for the three floating-point types, as follows:

```
int fpclassify(float x);
bool isfinite(float x);
bool isinf(float x);
bool isnan(float x);
bool isnormal(float x);
bool signbit(float x);

bool isgreater(float x, float y);
bool isgreaterequal(float x, float y);
bool isless(float x, float y);
bool islessequal(float x, float y);
bool islessgreater(float x, float y);
bool isunordered(float x, float y);

int fpclassify(double x);
```

```
bool isfinite(double x);
bool isinf(double x);
bool isnan(double x);
bool isnormal(double x);
bool signbit(double x);

bool isgreater(double x, double y);
bool isgreaterequal(double x, double y);
bool isless(double x, double y);
bool islessequal(double x, double y);
bool islessgreater(double x, double y);
bool isunordered(double x, double y);

int fpclassify(long double x);
bool isfinite(long double x);
bool isinf(long double x);
bool isnan(long double x);
bool isnormal(long double x);
bool signbit(long double x);

bool isgreater(long double x, long double y);
bool isgreaterequal(long double x, long double y);
bool isless(long double x, long double y);
bool islessequal(long double x, long double y);
bool islessgreater(long double x, long double y);
bool isunordered(long double x, long double y);
```

1

Moreover, there shall be additional overloads sufficient to ensure:

1. If any arithmetic argument corresponding to a `double` parameter has type `long double`, then all arithmetic arguments corresponding to `double` parameters are effectively cast to `long double`.
2. Otherwise, if any arithmetic argument corresponding to a `double` parameter has type `double` or an integer type, then all arithmetic arguments corresponding to `double` parameters are effectively cast to `double`.
3. Otherwise, all arithmetic arguments corresponding to `double` parameters have type `float`.

See also: ISO C 7.5, 7.10.2, 7.10.6.

27 Input/output library [input.output]

27.1 General [input.output.general]

1 This Clause describes components that C++ programs may use to perform input/output operations.

2 The following subclauses describe requirements for stream parameters, and components for forward declarations of iostreams, predefined iostreams objects, base iostreams classes, stream buffering, stream formatting and manipulators, string streams, and file streams, as summarized in Table 121.

Table 121 — Input/output library summary

Subclause		Header(s)
27.2	Requirements	
27.16	Forward declarations	`<iosfwd>`
27.17	Standard iostream objects	`<iostream>`
27.56	Iostreams base classes	`<ios>`
27.92	Stream buffers	`<streambuf>`

27.109	Formatting and manipulators	`<istream>`
		`<ostream>`
		`<iomanip>`

27.243	String streams	`<sstream>`

27.248	File streams	`<fstream>`
		`<cstdio>`
		`<cinttypes>`

3 Figure 7 illustrates relationships among various types described in this clause. A line from **A** to **B** indicates that **A** is an alias (e.g. a typedef) for **B** or that **A** is defined in terms of **B**.

Figure 7 — Stream position, offset, and size types [non-normative]

27.2 Iostreams requirements [iostreams.requirements]

27.2.1 Imbue limitations [iostream.limits.imbue]

1 No function described in Clause 27 except for `ios_base::imbue` and `basic_filebuf::pubimbue` causes any instance of `basic_ios::imbue` or `basic_streambuf::imbue` to be called. If any user function called from a function declared in Clause 27 or as an overriding virtual function of any class declared in Clause 27 calls `imbue`, the behavior is undefined.

27.2.2 Positioning type limitations [iostreams.limits.pos]

1 The classes of Clause 27 with template arguments `charT` and `traits` behave as described if `traits::pos_type` and `traits::off_type` are `streampos` and `streamoff` respectively. Except as noted explicitly below, their behavior when `traits::pos_type` and `traits::off_type` are other types is implementation-defined.

2

In the classes of Clause 27, a template parameter with name `charT` represents a member of the set of types containing `char`, `wchar_t`, and any other implementation-defined character types that satisfy the requirements for a character on which any of the iostream components can be instantiated.

27.6.1 Thread safety [iostreams.threadsafety]

1

Concurrent access to a stream object (27.243, 27.248), stream buffer object (27.92), or C Library stream (27.310.1) by multiple threads may result in a data race (1.859) unless otherwise specified (27.17). [*Note:* Data races result in undefined behavior (1.859). — *end note*]

1

If one thread makes a library call a that writes a value to a stream and, as a result, another thread reads this value from the stream through a library call b such that this does not result in a data race, then a's write synchronizes with b's read.

27.16 Forward declarations [iostream.forward]

Header `<iosfwd>` synopsis

```
namespace std {
  template<class charT> class char_traits;
  template<> class char_traits<char>;
  template<> class char_traits<char16_t>;
  template<> class char_traits<char32_t>;
  template<> class char_traits<wchar_t>;

  template<class T> class allocator;

  template <class charT, class traits = char_traits<charT> >
    class basic_ios;
  template <class charT, class traits = char_traits<charT> >
    class basic_streambuf;
  template <class charT, class traits = char_traits<charT> >
    class basic_istream;
  template <class charT, class traits = char_traits<charT> >
    class basic_ostream;
  template <class charT, class traits = char_traits<charT> >
    class basic_iostream;

  template <class charT, class traits = char_traits<charT>,
```

```
    class Allocator = allocator<charT> >
  class basic_stringbuf;
template <class charT, class traits = char_traits<charT>,
    class Allocator = allocator<charT> >
  class basic_istringstream;
template <class charT, class traits = char_traits<charT>,
    class Allocator = allocator<charT> >
  class basic_ostringstream;
template <class charT, class traits = char_traits<charT>,
    class Allocator = allocator<charT> >
  class basic_stringstream;

template <class charT, class traits = char_traits<charT> >
  class basic_filebuf;
template <class charT, class traits = char_traits<charT> >
  class basic_ifstream;
template <class charT, class traits = char_traits<charT> >
  class basic_ofstream;
template <class charT, class traits = char_traits<charT> >
  class basic_fstream;

template <class charT, class traits = char_traits<charT> >
  class istreambuf_iterator;
template <class charT, class traits = char_traits<charT> >
  class ostreambuf_iterator;

typedef basic_ios<char>       ios;
typedef basic_ios<wchar_t>    wios;

typedef basic_streambuf<char> streambuf;
typedef basic_istream<char>   istream;
typedef basic_ostream<char>   ostream;
typedef basic_iostream<char>  iostream;

typedef basic_stringbuf<char>     stringbuf;
typedef basic_istringstream<char> istringstream;
typedef basic_ostringstream<char> ostringstream;
typedef basic_stringstream<char>  stringstream;

typedef basic_filebuf<char>  filebuf;
typedef basic_ifstream<char> ifstream;
typedef basic_ofstream<char> ofstream;
typedef basic_fstream<char>  fstream;

typedef basic_streambuf<wchar_t> wstreambuf;
typedef basic_istream<wchar_t>   wistream;
typedef basic_ostream<wchar_t>   wostream;
typedef basic_iostream<wchar_t>  wiostream;

typedef basic_stringbuf<wchar_t>     wstringbuf;
typedef basic_istringstream<wchar_t> wistringstream;
typedef basic_ostringstream<wchar_t> wostringstream;
typedef basic_stringstream<wchar_t>  wstringstream;

typedef basic_filebuf<wchar_t>  wfilebuf;
```

```
  typedef basic_ifstream<wchar_t> wifstream;
  typedef basic_ofstream<wchar_t> wofstream;
  typedef basic_fstream<wchar_t>  wfstream;

  template <class state> class fpos;
  typedef fpos<char_traits<char>::state_type>    streampos;
  typedef fpos<char_traits<wchar_t>::state_type> wstreampos;
}
```

1 Default template arguments are described as appearing both in `<iosfwd>` and in the synopsis of other headers but it is well-formed to include both `<iosfwd>` and one or more of the other headers.[293]

2 [*Note:* The class template specialization `basic_ios<charT,traits>` serves as a virtual base class for the class templates `basic_istream`, `basic_ostream`, and class templates derived from them. `basic_iostream` is a class template derived from both `basic_istream<charT,traits>` and `basic_ostream<charT,traits>`.

3 The class template specialization `basic_streambuf<charT,traits>` serves as a base class for class templates `basic_stringbuf` and `basic_filebuf`.

4 The class template specialization `basic_istream<charT,traits>` serves as a base class for class templates `basic_istringstream` and `basic_ifstream`.

5 The class template specialization `basic_ostream<charT,traits>` serves as a base class for class templates `basic_ostringstream` and `basic_ofstream`.

6 The class template specialization `basic_iostream<charT,traits>` serves as a base class for class templates `basic_stringstream` and `basic_fstream`.

7 Other typedefs define instances of class templates specialized for `char` or `wchar_t` types.

8 Specializations of the class template `fpos` are used for specifying file position information.

9 The types `streampos` and `wstreampos` are used for positioning streams specialized on `char` and `wchar_t` respectively.

10 This synopsis suggests a circularity between `streampos` and `char_traits<char>`. An implementation can avoid this circularity by substituting equivalent types. One way to do this might be

```
template<class stateT> class fpos { ... };       // depends on nothing
typedef ... _STATE;              // implementation private declaration of stateT

typedef fpos<_STATE> streampos;

template<> struct char_traits<char> {
  typedef streampos
  pos_type;
}
```

— *end note*]

27.17 Standard iostream objects [iostream.objects]

27.17.1 Overview [iostream.objects.overview]

Header `<iostream>` synopsis

```
#include <ios>
#include <streambuf>
```

293) It is the implementation's responsibility to implement headers so that including `<iosfwd>` and other headers does not violate the rules about multiple occurrences of default arguments.

```
#include <istream>
#include <ostream>

namespace std {
  extern istream cin;
  extern ostream cout;
  extern ostream cerr;
  extern ostream clog;

  extern wistream wcin;
  extern wostream wcout;
  extern wostream wcerr;
  extern wostream wclog;
}
```

1

The header `<iostream>` declares objects that associate objects with the standard C streams provided for by the functions declared in `<cstdio>` (27.310.1), and includes all the headers necessary to use these objects.

1

The objects are constructed and the associations are established at some time prior to or during the first time an object of class `ios_base::Init` is constructed, and in any case before the body of `main` begins execution.[294] The objects are not destroyed during program execution.[295] The results of including `<iostream>` in a translation unit shall be as if `<iostream>` defined an instance of `ios_base::Init` with static storage duration. Similarly, the entire program shall behave as if there were at least one instance of `ios_base::Init` with static storage duration.

1

Mixing operations on corresponding wide- and narrow-character streams follows the same semantics as mixing such operations on `FILE`s, as specified in Amendment 1 of the ISO C standard.

1

Concurrent access to a synchronized (27.76.0.1) standard iostream object's formatted and unformatted input (27.109.2.1) and output (27.187.1.1) functions or a standard C stream by multiple threads shall not result in a data race (1.859). [*Note:* Users must still synchronize concurrent use of these objects and streams by multiple threads if they wish to avoid interleaved characters. — *end note*]

27.48.1 Narrow stream objects [narrow.stream.objects]

`istream cin;`

1

The object `cin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>`.

1

After the object `cin` is initialized, `cin.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (27.78.2.2).

`ostream cout;`

294) If it is possible for them to do so, implementations are encouraged to initialize the objects earlier than required.
295) Constructors and destructors for static objects can access these objects to read input from `stdin` or write output to `stdout` or `stderr`.

1 The object `cout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (27.310.1).

`ostream cerr;`

1 The object `cerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (27.310.1).

2 After the object `cerr` is initialized, `cerr.flags() & unitbuf` is nonzero and `cerr.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (27.78.2.2).

`ostream clog;`

3 The object `clog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (27.310.1).

27.53.1 Wide stream objects [wide.stream.objects]

`wistream wcin;`

1 The object `wcin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>`.

2 After the object `wcin` is initialized, `wcin.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (27.78.2.2).

`wostream wcout;`

1 The object `wcout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (27.310.1).

`wostream wcerr;`

1 The object `wcerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (27.310.1).

2 After the object `wcerr` is initialized, `wcerr.flags() & unitbuf` is nonzero and `wcerr.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (27.78.2.2).

`wostream wclog;`

3 The object `wclog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (27.310.1).

27.56 Iostreams base classes [iostreams.base]

27.56.1 Overview [iostreams.base.overview]

Header `<ios>` synopsis

```
#include <iosfwd>

namespace std {
  typedef implementation-defined streamoff;
  typedef implementation-defined streamsize;
  template <class stateT> class fpos;
```

```
  class ios_base;
  template <class charT, class traits = char_traits<charT> >
    class basic_ios;

  // 27.91.1, manipulators:
  ios_base& boolalpha  (ios_base& str);
  ios_base& noboolalpha(ios_base& str);

  ios_base& showbase   (ios_base& str);
  ios_base& noshowbase (ios_base& str);

  ios_base& showpoint  (ios_base& str);
  ios_base& noshowpoint(ios_base& str);

  ios_base& showpos    (ios_base& str);
  ios_base& noshowpos  (ios_base& str);

  ios_base& skipws     (ios_base& str);
  ios_base& noskipws   (ios_base& str);

  ios_base& uppercase  (ios_base& str);
  ios_base& nouppercase(ios_base& str);

  ios_base& unitbuf    (ios_base& str);
  ios_base& nounitbuf  (ios_base& str);

  // 27.91.1.2 adjustfield:
  ios_base& internal   (ios_base& str);
  ios_base& left       (ios_base& str);
  ios_base& right      (ios_base& str);

  // 27.91.1.3 basefield:
  ios_base& dec        (ios_base& str);
  ios_base& hex        (ios_base& str);
  ios_base& oct        (ios_base& str);

  // 27.91.1.4 floatfield:
  ios_base& fixed      (ios_base& str);
  ios_base& scientific (ios_base& str);
  ios_base& hexfloat   (ios_base& str);
  ios_base& defaultfloat(ios_base& str);

  // 27.91.1.5 error reporting:
  enum class io_errc {
    stream = 1
  };

  template <> struct is_error_code_enum<io_errc> : public true_type { };
  error_code make_error_code(io_errc e) noexcept;
  error_condition make_error_condition(io_errc e) noexcept;
  const error_category& iostream_category() noexcept;
}
```

27.56.2 Types [stream.types]

```
typedef implementation-defined streamoff;
```

1 The type `streamoff` is a synonym for one of the signed basic integral types of sufficient size to represent the maximum possible file size for the operating system.[296]

```
typedef implementation-defined streamsize;
```

2 The type `streamsize` is a synonym for one of the signed basic integral types. It is used to represent the number of characters transferred in an I/O operation, or the size of I/O buffers.[297]

27.58.1 Class ios_base [ios.base]

```
namespace std {
  class ios_base {
  public:
    class failure;

    // 27.61.0.0.1 fmtflags
    typedef T1 fmtflags;
    static constexpr fmtflags boolalpha = unspecified ;
    static constexpr fmtflags dec = unspecified ;
    static constexpr fmtflags fixed = unspecified ;
    static constexpr fmtflags hex = unspecified ;
    static constexpr fmtflags internal = unspecified ;
    static constexpr fmtflags left = unspecified ;
    static constexpr fmtflags oct = unspecified ;
    static constexpr fmtflags right = unspecified ;
    static constexpr fmtflags scientific = unspecified ;
    static constexpr fmtflags showbase = unspecified ;
    static constexpr fmtflags showpoint = unspecified ;
    static constexpr fmtflags showpos = unspecified ;
    static constexpr fmtflags skipws = unspecified ;
    static constexpr fmtflags unitbuf = unspecified ;
    static constexpr fmtflags uppercase = unspecified ;
    static constexpr fmtflags adjustfield = see below;
    static constexpr fmtflags basefield = see below;
    static constexpr fmtflags floatfield = see below;

    // 27.61.0.0.2 iostate
    typedef T2 iostate;
    static constexpr iostate badbit = unspecified ;
    static constexpr iostate eofbit = unspecified ;
    static constexpr iostate failbit = unspecified ;
    static constexpr iostate goodbit = see below;

    // 27.66.0.0.1 openmode
    typedef T3 openmode;
    static constexpr openmode app = unspecified ;
    static constexpr openmode ate = unspecified ;
    static constexpr openmode binary = unspecified ;
    static constexpr openmode in = unspecified ;
```

296) Typically `long long`.

297) `streamsize` is used in most places where ISO C would use `size_t`. Most of the uses of `streamsize` could use `size_t`, except for the `strstreambuf` constructors, which require negative values. It should probably be the signed type corresponding to `size_t` (which is what Posix.2 calls `ssize_t`).

```
    static constexpr openmode out = unspecified ;
    static constexpr openmode trunc = unspecified ;

    // 27.69.0.0.1 seekdir
    typedef T4 seekdir;
    static constexpr seekdir beg = unspecified ;
    static constexpr seekdir cur = unspecified ;
    static constexpr seekdir end = unspecified ;

    class Init;

    // 27.72.0.1 fmtflags state:
    fmtflags flags() const;
    fmtflags flags(fmtflags fmtfl);
    fmtflags setf(fmtflags fmtfl);
    fmtflags setf(fmtflags fmtfl, fmtflags mask);
    void unsetf(fmtflags mask);

    streamsize precision() const;
    streamsize precision(streamsize prec);
    streamsize width() const;
    streamsize width(streamsize wide);

    // 27.74.0.1 locales:
    locale imbue(const locale& loc);
    locale getloc() const;

    // 27.77.0.1 storage:
    static int xalloc();
    long&  iword(int index);
    void*& pword(int index);

    // destructor
    virtual ~ios_base();

    // 27.78.0.1 callbacks;
    enum event { erase_event, imbue_event, copyfmt_event };
    typedef void (*event_callback)(event, ios_base&, int index);
    void register_callback(event_callback fn, int index);

    ios_base(const ios_base&) = delete;
    ios_base& operator=(const ios_base&) = delete;

    static bool sync_with_stdio(bool sync = true);

  protected:
    ios_base();

  private:
    static int index;  // exposition only
    long* iarray;      // exposition only
    void** parray;     // exposition only
  };
}
```

1 `ios_base` defines several member types:

(1.1) — a class `failure` derived from `system_error`;

(1.2) — a class `Init`;

(1.3) — three bitmask types, `fmtflags`, `iostate`, and `openmode`;

(1.4) — an enumerated type, `seekdir`.

2

It maintains several kinds of data:

— state information that reflects the integrity of the stream buffer;

— control information that influences how to interpret (format) input sequences and how to generate (format) output sequences;

— additional information that is stored by the program for its private use.

1 [*Note:* For the sake of exposition, the maintained data is presented here as:

(1.1) — `static int index`, specifies the next available unique index for the integer or pointer arrays maintained for the private use of the program, initialized to an unspecified value;

(1.2) — `long* iarray`, points to the first element of an arbitrary-length `long` array maintained for the private use of the program;

(1.3) — `void** parray`, points to the first element of an arbitrary-length pointer array maintained for the private use of the program. — *end note*]

27.59.0.1 Types [ios.types]

27.59.0.1.1 Class `ios_base::failure` [ios::failure]

```
namespace std {
  class ios_base::failure : public system_error {
  public:
    explicit failure(const string& msg, const error_code& ec = io_errc::stream);
    explicit failure(const char* msg, const error_code& ec = io_errc::stream);
  };
}
```

1

The class `failure` defines the base class for the types of all objects thrown as exceptions, by functions in the iostreams library, to report errors detected during stream buffer operations.

1 When throwing `ios_base::failure` exceptions, implementations should provide values of `ec` that identify the specific reason for the failure. [*Note:* Errors arising from the operating system would typically be reported as `system_category()` errors with an error value of the error number reported by the operating system. Errors arising from within the stream library would typically be reported as `error_code(io_errc::stream, iostream_category())`. — *end note*]

`explicit failure(const string& msg, const error_code& ec = io_errc::stream);`

2 *Effects:* Constructs an object of class `failure` by constructing the base class with `msg` and `ec`.

`explicit failure(const char* msg, const error_code& ec = io_errc::stream);`

3 *Effects:* Constructs an object of class `failure` by constructing the base class with `msg` and `ec`.

27.61.0.0.1 Type `ios_base::fmtflags` [ios::fmtflags]

```
typedef T1 fmtflags;
```

1 The type `fmtflags` is a bitmask type (17.20.0.0.1). Setting its elements has the effects indicated in Table 122.

Table 122 — `fmtflags` effects

Element	Effect(s) if set
`boolalpha`	insert and extract `bool` type in alphabetic format
`dec`	converts integer input or generates integer output in decimal base
`fixed`	generate floating-point output in fixed-point notation
`hex`	converts integer input or generates integer output in hexadecimal base
`internal`	adds fill characters at a designated internal point in certain generated output, or identical to `right` if no such point is designated
`left`	adds fill characters on the right (final positions) of certain generated output
`oct`	converts integer input or generates integer output in octal base
`right`	adds fill characters on the left (initial positions) of certain generated output
`scientific`	generates floating-point output in scientific notation
`showbase`	generates a prefix indicating the numeric base of generated integer output
`showpoint`	generates a decimal-point character unconditionally in generated floating-point output
`showpos`	generates a `+` sign in non-negative generated numeric output
`skipws`	skips leading whitespace before certain input operations
`unitbuf`	flushes output after each output operation
`uppercase`	replaces certain lowercase letters with their uppercase equivalents in generated output

2 Type `fmtflags` also defines the constants indicated in Table 123.

Table 123 — `fmtflags` constants

Constant	Allowable values
`adjustfield`	`left | right | internal`
`basefield`	`dec | oct | hex`
`floatfield`	`scientific | fixed`

27.61.0.0.2 Type `ios_base::iostate` [ios::iostate]

```
typedef T2 iostate;
```

1

The type `iostate` is a bitmask type (17.20.0.0.1) that contains the elements indicated in Table 124.

1 Type `iostate` also defines the constant:

(1.1) — `goodbit`, the value zero.

27.66.0.0.1 Type `ios_base::openmode` [ios::openmode]

```
typedef T3 openmode;
```

1

The type `openmode` is a bitmask type (17.20.0.0.1). It contains the elements indicated in Table 125.

Table 124 — `iostate` effects

Element	Effect(s) if set
`badbit`	indicates a loss of integrity in an input or output sequence (such as an irrecoverable read error from a file);
`eofbit`	indicates that an input operation reached the end of an input sequence;
`failbit`	indicates that an input operation failed to read the expected characters, or that an output operation failed to generate the desired characters.

Table 125 — `openmode` effects

Element	Effect(s) if set
`app`	seek to end before each write
`ate`	open and seek to end immediately after opening
`binary`	perform input and output in binary mode (as opposed to text mode)
`in`	open for input
`out`	open for output
`trunc`	truncate an existing stream when opening

27.69.0.0.1 Type `ios_base::seekdir` [ios::seekdir]

```
typedef T4 seekdir;
```

1

The type `seekdir` is an enumerated type (17.17.1.1.2) that contains the elements indicated in Table 126.

Table 126 — `seekdir` effects

Element	Meaning
`beg`	request a seek (for subsequent input or output) relative to the beginning of the stream
`cur`	request a seek relative to the current position within the sequence
`end`	request a seek relative to the current end of the sequence

27.70.0.0.1 Class `ios_base::Init` [ios::Init]

```
namespace std {
  class ios_base::Init {
  public:
    Init();
   ~Init();
  private:
    static int init_cnt; // exposition only
  };
}
```

1 The class `Init` describes an object whose construction ensures the construction of the eight objects declared in `<iostream>` (27.17) that associate file stream buffers with the standard C streams provided for by the functions declared in `<cstdio>` (27.310.1).

2

For the sake of exposition, the maintained data is presented here as:

— `static int init_cnt`, counts the number of constructor and destructor calls for class `Init`, initialized to zero.

`Init();`

1 *Effects:* Constructs an object of class `Init`. Constructs and initializes the objects `cin`, `cout`, `cerr`, `clog`, `wcin`, `wcout`, `wcerr`, and `wclog` if they have not already been constructed and initialized.

`~Init();`

2 *Effects:* Destroys an object of class `Init`. If there are no other instances of the class still in existence, calls `cout.flush()`, `cerr.flush()`, `clog.flush()`, `wcout.flush()`, `wcerr.flush()`, `wclog.flush()`.

27.72.0.1 `ios_base` state functions [fmtflags.state]

`fmtflags flags() const;`

1 *Returns:* The format control information for both input and output.

`fmtflags flags(fmtflags fmtfl);`

2 *Postcondition:* `fmtfl == flags()`.

3 *Returns:* The previous value of `flags()`.

`fmtflags setf(fmtflags fmtfl);`

4 *Effects:* Sets `fmtfl` in `flags()`.

5 *Returns:* The previous value of `flags()`.

`fmtflags setf(fmtflags fmtfl, fmtflags mask);`

6 *Effects:* Clears `mask` in `flags()`, sets `fmtfl & mask` in `flags()`.

1 *Returns:* The previous value of `flags()`.

`void unsetf(fmtflags mask);`

2 *Effects:* Clears `mask` in `flags()`.

`streamsize precision() const;`

3 *Returns:* The precision to generate on certain output conversions.

`streamsize precision(streamsize prec);`

4 *Postcondition:* `prec == precision()`.

5 *Returns:* The previous value of `precision()`.

`streamsize width() const;`

6 *Returns:* The minimum field width (number of characters) to generate on certain output conversions.

`streamsize width(streamsize wide);`

1 *Postcondition:* `wide == width()`.

2 *Returns:* The previous value of `width()`.

27.74.0.1 `ios_base` functions [ios.base.locales]

`locale imbue(const locale& loc);`

1 *Effects:* Calls each registered callback pair `(fn,index)` (27.78.0.1) as `(*fn)(imbue_event,*this,index)` at such a time that a call to `ios_base::getloc()` from within `fn` returns the new locale value `loc`.

2 *Returns:* The previous value of `getloc()`.

3 *Postcondition:* `loc == getloc()`.

`locale getloc() const;`

4

Returns: If no locale has been imbued, a copy of the global C++ locale, `locale()`, in effect at the time of construction. Otherwise, returns the imbued locale, to be used to perform locale-dependent input and output operations.

27.76.0.1 `ios_base` static members [ios.members.static]

`bool sync_with_stdio(bool sync = true);`

1 *Returns:* `true` if the previous state of the standard iostream objects (27.17) was synchronized and otherwise returns `false`. The first time it is called, the function returns `true`.

2

Effects: If any input or output operation has occurred using the standard streams prior to the call, the effect is implementation-defined. Otherwise, called with a false argument, it allows the standard streams to operate independently of the standard C streams.

1 When a standard iostream object `str` is *synchronized* with a standard stdio stream `f`, the effect of inserting a character `c` by

```
fputc(f, c);
```

is the same as the effect of

```
str.rdbuf()->sputc(c);
```

for any sequences of characters; the effect of extracting a character `c` by

```
c = fgetc(f);
```

is the same as the effect of

```
c = str.rdbuf()->sbumpc();
```

for any sequences of characters; and the effect of pushing back a character `c` by

```
ungetc(c, f);
```

is the same as the effect of

```
str.rdbuf()->sputbackc(c);
```

for any sequence of characters.[298]

298) This implies that operations on a standard iostream object can be mixed arbitrarily with operations on the corresponding stdio stream. In practical terms, synchronization usually means that a standard iostream object and a standard stdio object share a buffer.

27.77.0.1 `ios_base` storage functions [ios.base.storage]

```
static int xalloc();
```

1 *Returns:* `index ++`.

2 *Remarks:* Concurrent access to this function by multiple threads shall not result in a data race (1.859).

```
long& iword(int idx);
```

3

Effects: If `iarray` is a null pointer, allocates an array of `long` of unspecified size and stores a pointer to its first element in `iarray`. The function then extends the array pointed at by `iarray` as necessary to include the element `iarray[idx]`. Each newly allocated element of the array is initialized to zero. The reference returned is invalid after any other operations on the object.[299] However, the value of the storage referred to is retained, so that until the next call to `copyfmt`, calling `iword` with the same index yields another reference to the same value. If the function fails[300] and `*this` is a base subobject of a `basic_ios<>` object or subobject, the effect is equivalent to calling `basic_ios<>::setstate(badbit)` on the derived object (which may throw `failure`).

1 *Returns:* On success `iarray[idx]`. On failure, a valid `long&` initialized to 0.

```
void*& pword(int idx);
```

2 *Effects:* If `parray` is a null pointer, allocates an array of pointers to `void` of unspecified size and stores a pointer to its first element in `parray`. The function then extends the array pointed at by `parray` as necessary to include the element `parray[idx]`. Each newly allocated element of the array is initialized to a null pointer. The reference returned is invalid after any other operations on the object. However, the value of the storage referred to is retained, so that until the next call to `copyfmt`, calling `pword` with the same index yields another reference to the same value. If the function fails[301] and `*this` is a base subobject of a `basic_ios<>` object or subobject, the effect is equivalent to calling `basic_ios<>::setstate(badbit)` on the derived object (which may throw `failure`).

3 *Returns:* On success `parray[idx]`. On failure a valid `void*&` initialized to 0.

4 *Remarks:* After a subsequent call to `pword(int)` for the same object, the earlier return value may no longer be valid.

27.78.0.1 `ios_base` callbacks [ios.base.callback]

```
void register_callback(event_callback fn, int index);
```

1 *Effects:* Registers the pair `(fn,index)` such that during calls to `imbue()` (27.74.0.1), `copyfmt()`, or `~ios_base()` (27.78.0.2), the function `fn` is called with argument `index`. Functions registered are called when an event occurs, in opposite order of registration. Functions registered while a callback function is active are not called until the next event.

2 *Requires:* The function `fn` shall not throw exceptions.

Remarks: Identical pairs are not merged. A function registered twice will be called twice.

27.78.0.2 `ios_base` constructors/destructor [ios.base.cons]

```
ios_base();
```

299) An implementation is free to implement both the integer array pointed at by `iarray` and the pointer array pointed at by `parray` as sparse data structures, possibly with a one-element cache for each.
300) for example, because it cannot allocate space.
301) for example, because it cannot allocate space.

1 *Effects:* Each `ios_base` member has an indeterminate value after construction. The object's members shall be initialized by calling `basic_ios::init` before the object's first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

`~ios_base();`

2 *Effects:* Destroys an object of class `ios_base`. Calls each registered callback pair `(fn, index)` (27.78.0.1) as `(*fn)(erase_event, *this, index)` at such time that any `ios_base` member function called from within `fn` has well defined results.

27.78.1 Class template `fpos` [fpos]

```
namespace std {
  template <class stateT> class fpos {
  public:
    // 27.78.1.1 Members
    stateT state() const;
    void state(stateT);
  private;
    stateT st; // exposition only
  };
}
```

27.78.1.1 `fpos` members [fpos.members]

`void state(stateT s);`

1 *Effects:* Assign `s` to `st`.

`stateT state() const;`

2 *Returns:* Current value of `st`.

27.78.1.2 `fpos` requirements [fpos.operations]

1 Operations specified in Table 127 are permitted. In that table,

(1.1) — `P` refers to an instance of `fpos`,

(1.2) — `p` and `q` refer to values of type `P`,

(1.3) — `O` refers to type `streamoff`,

(1.4) — `o` refers to a value of type `streamoff`,

(1.5) — `sz` refers to a value of type `streamsize` and

(1.6) — `i` refers to a value of type `int`.

Table 127 — Position type requirements

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`P(i)`			`p == P(i)` note: a destructor is assumed.
`P p(i);` `P p = i;`			post: `p == P(i)`.

Table 127 — Position type requirements (continued)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`P(o)`	`fpos`	converts from `offset`	
`O(p)`	streamoff	converts to `offset`	`P(O(p)) == p`
`p == q`	convertible to `bool`		`==` is an equivalence relation
`p != q`	convertible to `bool`	`!(p == q)`	
`q = p + o` `p += o`	`fpos`	`+` offset	`q - o == p`
`q = p - o` `p -= o`	`fpos`	`-` offset	`q + o == p`
`o = p - q`	streamoff	distance	`q + o == p`
`streamsize(o)`	`streamsize`	converts	`streamsize(O(sz)) == sz`
`O(sz)`	streamoff	converts	`streamsize(O(sz)) == sz`

2 [*Note:* Every implementation is required to supply overloaded operators on `fpos` objects to satisfy the requirements of 27.78.1.2. It is unspecified whether these operators are members of `fpos`, global operators, or provided in some other way. — *end note*]

3 Stream operations that return a value of type `traits::pos_type` return `P(O(-1))` as an invalid value to signal an error. If this value is used as an argument to any `istream`, `ostream`, or `streambuf` member that accepts a value of type `traits::pos_type` then the behavior of that function is undefined.

27.78.2 Class template `basic_ios` [ios]

27.78.2.1 Overview [ios.overview]

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
  class basic_ios : public ios_base {
  public:

    // types:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;

    explicit operator bool() const;
    bool operator!() const;
    iostate rdstate() const;
    void clear(iostate state = goodbit);
    void setstate(iostate state);
    bool good() const;
    bool eof()  const;
    bool fail() const;
    bool bad()  const;

    iostate exceptions() const;
    void exceptions(iostate except);

    // 27.78.2.2 Constructor/destructor:
```

```
    explicit basic_ios(basic_streambuf<charT,traits>* sb);
    virtual ~basic_ios();

    // 27.83.0.1 Members:
    basic_ostream<charT,traits>* tie() const;
    basic_ostream<charT,traits>* tie(basic_ostream<charT,traits>* tiestr);

    basic_streambuf<charT,traits>* rdbuf() const;
    basic_streambuf<charT,traits>* rdbuf(basic_streambuf<charT,traits>* sb);

    basic_ios& copyfmt(const basic_ios& rhs);

    char_type fill() const;
    char_type fill(char_type ch);

    locale imbue(const locale& loc);

    char     narrow(char_type c, char dfault) const;
    char_type widen(char c) const;

    basic_ios(const basic_ios&) = delete;
    basic_ios& operator=(const basic_ios&) = delete;

  protected:
    basic_ios();
    void init(basic_streambuf<charT,traits>* sb);
    void move(basic_ios& rhs);
    void move(basic_ios&& rhs);
    void swap(basic_ios& rhs) noexcept;
    void set_rdbuf(basic_streambuf<charT, traits>* sb);

  };
}
```

27.78.2.2 `basic_ios` constructors [basic.ios.cons]

`explicit basic_ios(basic_streambuf<charT,traits>* sb);`

1 *Effects:* Constructs an object of class `basic_ios`, assigning initial values to its member objects by calling `init(sb)`.

`basic_ios();`

1 *Effects:* Constructs an object of class `basic_ios` (27.78.0.2) leaving its member objects uninitialized. The object shall be initialized by calling `basic_ios::init` before its first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

`~basic_ios();`

1 *Remarks:* The destructor does not destroy `rdbuf()`.

`void init(basic_streambuf<charT,traits>* sb);`

Postconditions: The postconditions of this function are indicated in Table 128.

Table 128 — `basic_ios::init()` effects

Element	Value
`rdbuf()`	`sb`
`tie()`	`0`
`rdstate()`	`goodbit` if `sb` is not a null pointer, otherwise `badbit`.
`exceptions()`	`goodbit`
`flags()`	`skipws | dec`
`width()`	`0`
`precision()`	`6`
`fill()`	`widen(' ');`
`getloc()`	a copy of the value returned by `locale()`
`iarray`	a null pointer
`parray`	a null pointer

27.83.0.1 Member functions [basic.ios.members]

`basic_ostream<charT,traits>* tie() const;`

1 *Returns:* An output sequence that is *tied* to (synchronized with) the sequence controlled by the stream buffer.

`basic_ostream<charT,traits>* tie(basic_ostream<charT,traits>* tiestr);`

2 *Requires:* If `tiestr` is not null, `tiestr` must not be reachable by traversing the linked list of tied stream objects starting from `tiestr->tie()`.

3 *Postcondition:* `tiestr == tie()`.

4 *Returns:* The previous value of `tie()`.

`basic_streambuf<charT,traits>* rdbuf() const;`

5 *Returns:* A pointer to the `streambuf` associated with the stream.

`basic_streambuf<charT,traits>* rdbuf(basic_streambuf<charT,traits>* sb);`

6 *Postcondition:* `sb == rdbuf()`.

7 *Effects:* Calls `clear()`.

8 *Returns:* The previous value of `rdbuf()`.

`locale imbue(const locale& loc);`

9 *Effects:* Calls `ios_base::imbue(loc)` (27.74.0.1) and if `rdbuf()!=0` then `rdbuf()->pubimbue(loc)` (27.96.0.2.1).

10 *Returns:* The prior value of `ios_base::imbue()`.

`char narrow(char_type c, char dfault) const;`

11 *Returns:* `use_facet< ctype<char_type> >(getloc()).narrow(c,dfault)`

`char_type widen(char c) const;`

12 *Returns:* `use_facet< ctype<char_type> >(getloc()).widen(c)`

`char_type fill() const;`

13 *Returns:* The character used to pad (fill) an output conversion to the specified field width.

```
char_type fill(char_type fillch);
```

14 *Postcondition:* `traits::eq(fillch, fill())`

15 *Returns:* The previous value of `fill()`.

```
basic_ios& copyfmt(const basic_ios& rhs);
```

16 *Effects:* If `(this == &rhs)` does nothing. Otherwise assigns to the member objects of `*this` the corresponding member objects of `rhs` as follows:

1. calls each registered callback pair `(fn, index)` as `(*fn)(erase_event, *this, index)`;
2. assigns to the member objects of `*this` the corresponding member objects of `rhs`, except that
   - (16.1) — `rdstate()`, `rdbuf()`, and `exceptions()` are left unchanged;
   - (16.2) — the contents of arrays pointed at by `pword` and `iword` are copied, not the pointers themselves;[302] and
   - (16.3) — if any newly stored pointer values in `*this` point at objects stored outside the object `rhs` and those objects are destroyed when `rhs` is destroyed, the newly stored pointer values are altered to point at newly constructed copies of the objects;
3. calls each callback pair that was copied from `rhs` as `(*fn)(copyfmt_event, *this, index)`;
4. calls `exceptions(rhs.except())`.

17 *Note:* The second pass through the callback pairs permits a copied `pword` value to be zeroed, or to have its referent deep copied or reference counted, or to have other special action taken.

18 *Postconditions:* The postconditions of this function are indicated in Table 129.

Table 129 — `basic_ios::copyfmt()` effects

Element	Value
`rdbuf()`	*unchanged*
`tie()`	`rhs.tie()`
`rdstate()`	*unchanged*
`exceptions()`	`rhs.exceptions()`
`flags()`	`rhs.flags()`
`width()`	`rhs.width()`
`precision()`	`rhs.precision()`
`fill()`	`rhs.fill()`
`getloc()`	`rhs.getloc()`

19 *Returns:* `*this`.

```
void move(basic_ios& rhs);
void move(basic_ios&& rhs);
```

20 *Postconditions:* `*this` shall have the state that `rhs` had before the function call, except that `rdbuf()` shall return 0. `rhs` shall be in a valid but unspecified state, except that `rhs.rdbuf()` shall return the same value as it returned before the function call, and `rhs.tie()` shall return 0.

```
void swap(basic_ios& rhs) noexcept;
```

302) This suggests an infinite amount of copying, but the implementation can keep track of the maximum element of the arrays that is non-zero.

21

Effects: The states of `*this` and `rhs` shall be exchanged, except that `rdbuf()` shall return the same value as it returned before the function call, and `rhs.rdbuf()` shall return the same value as it returned before the function call.

```
void set_rdbuf(basic_streambuf<charT, traits>* sb);
```

1 *Requires:* `sb != nullptr`.

2 *Effects:* Associates the `basic_streambuf` object pointed to by `sb` with this stream without calling `clear()`.

3 *Postconditions:* `rdbuf() == sb`.

4 *Throws:* Nothing.

27.84.0.1 `basic_ios` flags functions [iostate.flags]

```
explicit operator bool() const;
```

1 *Returns:* `!fail()`.

```
bool operator!() const;
```

2 *Returns:* `fail()`.

```
iostate rdstate() const;
```

3

Returns: The error state of the stream buffer.

```
void clear(iostate state = goodbit);
```

1

Postcondition: If `rdbuf()!=0` then `state == rdstate()`; otherwise `rdstate()==(state | ios_base::badbit)`.

1

Effects: If `((state | (rdbuf() ? goodbit : badbit)) & exceptions()) == 0`, returns. Otherwise, the function throws an object `fail` of class `basic_ios::failure` (27.59.0.1.1), constructed with implementation-defined argument values.

```
void setstate(iostate state);
```

1

Effects: Calls `clear(rdstate() | state)` (which may throw `basic_ios::failure` (27.59.0.1.1)).

```
bool good() const;
```

1 *Returns:* `rdstate() == 0`

```
bool eof() const;
```

2 *Returns:* `true` if `eofbit` is set in `rdstate()`.

```
bool fail() const;
```

3 *Returns:* `true` if `failbit` or `badbit` is set in `rdstate()`.[303]

```
bool bad() const;
```

1 *Returns:* `true` if `badbit` is set in `rdstate()`.

```
iostate exceptions() const;
```

2 *Returns:* A mask that determines what elements set in `rdstate()` cause exceptions to be thrown.

```
void exceptions(iostate except);
```

1 *Postcondition:* `except == exceptions()`.

2 *Effects:* Calls `clear(rdstate())`.

27.91.1 `ios_base` manipulators [std.ios.manip]

27.91.1.1 `fmtflags` manipulators [fmtflags.manip]

```
ios_base& boolalpha(ios_base& str);
```

1 *Effects:* Calls `str.setf(ios_base::boolalpha)`.

2 *Returns:* `str`.

```
ios_base& noboolalpha(ios_base& str);
```

3 *Effects:* Calls `str.unsetf(ios_base::boolalpha)`.

4 *Returns:* `str`.

```
ios_base& showbase(ios_base& str);
```

5 *Effects:* Calls `str.setf(ios_base::showbase)`.

6 *Returns:* `str`.

```
ios_base& noshowbase(ios_base& str);
```

7 *Effects:* Calls `str.unsetf(ios_base::showbase)`.

8 *Returns:* `str`.

```
ios_base& showpoint(ios_base& str);
```

9 *Effects:* Calls `str.setf(ios_base::showpoint)`.

10 *Returns:* `str`.

```
ios_base& noshowpoint(ios_base& str);
```

11 *Effects:* Calls `str.unsetf(ios_base::showpoint)`.

12 *Returns:* `str`.

```
ios_base& showpos(ios_base& str);
```

13 *Effects:* Calls `str.setf(ios_base::showpos)`.

14 *Returns:* `str`.

303) Checking `badbit` also for `fail()` is historical practice.

`ios_base& noshowpos(ios_base& str);`

15 *Effects:* Calls `str.unsetf(ios_base::showpos)`.

16 *Returns:* `str`.

`ios_base& skipws(ios_base& str);`

17 *Effects:* Calls `str.setf(ios_base::skipws)`.

18 *Returns:* `str`.

`ios_base& noskipws(ios_base& str);`

19 *Effects:* Calls `str.unsetf(ios_base::skipws)`.

20 *Returns:* `str`.

`ios_base& uppercase(ios_base& str);`

21 *Effects:* Calls `str.setf(ios_base::uppercase)`.

22 *Returns:* `str`.

`ios_base& nouppercase(ios_base& str);`

23 *Effects:* Calls `str.unsetf(ios_base::uppercase)`.

24 *Returns:* `str`.

`ios_base& unitbuf(ios_base& str);`

25 *Effects:* Calls `str.setf(ios_base::unitbuf)`.

26 *Returns:* `str`.

`ios_base& nounitbuf(ios_base& str);`

27 *Effects:* Calls `str.unsetf(ios_base::unitbuf)`.

28 *Returns:* `str`.

27.91.1.2 `adjustfield` manipulators [adjustfield.manip]

`ios_base& internal(ios_base& str);`

1 *Effects:* Calls `str.setf(ios_base::internal, ios_base::adjustfield)`.

2 *Returns:* `str`.

`ios_base& left(ios_base& str);`

3 *Effects:* Calls `str.setf(ios_base::left, ios_base::adjustfield)`.

4 *Returns:* `str`.

`ios_base& right(ios_base& str);`

5 *Effects:* Calls `str.setf(ios_base::right, ios_base::adjustfield)`.

6 *Returns:* `str`.

27.91.1.3 `basefield` manipulators [basefield.manip]

`ios_base& dec(ios_base& str);`

1 *Effects:* Calls `str.setf(ios_base::dec, ios_base::basefield)`.

2 *Returns:* `str`[304].

`ios_base& hex(ios_base& str);`

3 *Effects:* Calls `str.setf(ios_base::hex, ios_base::basefield)`.

4 *Returns:* `str`.

`ios_base& oct(ios_base& str);`

5 *Effects:* Calls `str.setf(ios_base::oct, ios_base::basefield)`.

6 *Returns:* `str`.

27.91.1.4 `floatfield` manipulators [floatfield.manip]

`ios_base& fixed(ios_base& str);`

1 *Effects:* Calls `str.setf(ios_base::fixed, ios_base::floatfield)`.

2 *Returns:* `str`.

`ios_base& scientific(ios_base& str);`

3 *Effects:* Calls `str.setf(ios_base::scientific, ios_base::floatfield)`.

4 *Returns:* `str`.

`ios_base& hexfloat(ios_base& str);`

5 *Effects:* Calls `str.setf(ios_base::fixed | ios_base::scientific, ios_base::floatfield)`.

6 *Returns:* `str`.

7 [*Note:* The more obvious use of `ios_base::hex` to specify hexadecimal floating-point format would change the meaning of existing well defined programs. C++2003 gives no meaning to the combination of `fixed` and `scientific`. — *end note*]

`ios_base& defaultfloat(ios_base& str);`

8 *Effects:* Calls `str.unsetf(ios_base::floatfield)`.

9 *Returns:* `str`.

27.91.1.5 Error reporting [error.reporting]

`error_code make_error_code(io_errc e) noexcept;`

1 *Returns:* `error_code(static_cast<int>(e), iostream_category())`.

`error_condition make_error_condition(io_errc e) noexcept;`

2 *Returns:* `error_condition(static_cast<int>(e), iostream_category())`.

`const error_category& iostream_category() noexcept;`

304) The function signature `dec(ios_base&)` can be called by the function signature `basic_ostream& stream::operator<<(ios_base& (*)(ios_base&))` to permit expressions of the form `cout <<dec` to change the format flags stored in `cout`.

3 *Returns:* A reference to an object of a type derived from class `error_category`.

4 The object's `default_error_condition` and `equivalent` virtual functions shall behave as specified for the class `error_category`. The object's `name` virtual function shall return a pointer to the string `"iostream"`.

27.92 Stream buffers [stream.buffers]

27.92.1 Overview [stream.buffers.overview]

Header `<streambuf>` synopsis

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
    class basic_streambuf;
  typedef basic_streambuf<char>     streambuf;
  typedef basic_streambuf<wchar_t> wstreambuf;
}
```

1 The header `<streambuf>` defines types that control input from and output to *character* sequences.

27.92.2 Stream buffer requirements [streambuf.reqts]

1

Stream buffers can impose various constraints on the sequences they control. Some constraints are:

— The controlled input sequence can be not readable.

— The controlled output sequence can be not writable.

— The controlled sequences can be associated with the contents of other representations for character sequences, such as external files.

— The controlled sequences can support operations *directly* to or from associated sequences.

— The controlled sequences can impose limitations on how the program can read characters from a sequence, write characters to a sequence, put characters back into an input sequence, or alter the stream position.

1

Each sequence is characterized by three pointers which, if non-null, all point into the same `charT` array object. The array object represents, at any moment, a (sub)sequence of characters from the sequence. Operations performed on a sequence alter the values stored in these pointers, perform reads and writes directly to or from associated sequences, and alter "the stream position" and conversion state as needed to maintain this subsequence relationship. The three pointers are:

— the *beginning pointer*, or lowest element address in the array (called `xbeg` here);

— the *next pointer*, or next element address that is a current candidate for reading or writing (called `xnext` here);

— the *end pointer*, or first element address beyond the end of the array (called `xend` here).

1 The following semantic constraints shall always apply for any set of three pointers for a sequence, using the pointer names given immediately above:

(1.1) — If `xnext` is not a null pointer, then `xbeg` and `xend` shall also be non-null pointers into the same `charT` array, as described above; otherwise, `xbeg` and `xend` shall also be null.

(1.2) — If `xnext` is not a null pointer and `xnext < xend` for an output sequence, then a *write position* is available. In this case, `*xnext` shall be assignable as the next element to write (to put, or to store a character value, into the sequence).

(1.3) — If `xnext` is not a null pointer and `xbeg < xnext` for an input sequence, then a *putback position* is available. In this case, `xnext[-1]` shall have a defined value and is the next (preceding) element to store a character that is put back into the input sequence.

(1.4) — If `xnext` is not a null pointer and `xnext < xend` for an input sequence, then a *read position* is available. In this case, `*xnext` shall have a defined value and is the next element to read (to get, or to obtain a character value, from the sequence).

27.95.1 Class template `basic_streambuf<charT,traits>` [streambuf]

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
  class basic_streambuf {
  public:

    // types:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;

    virtual ~basic_streambuf();

    // 27.96.0.2.1 locales:
    locale   pubimbue(const locale& loc);
    locale   getloc() const;

    // 27.96.0.2.2 buffer and positioning:
    basic_streambuf<char_type,traits>*
       pubsetbuf(char_type* s, streamsize n);
    pos_type pubseekoff(off_type off, ios_base::seekdir way,
      ios_base::openmode which =
          ios_base::in | ios_base::out);
    pos_type pubseekpos(pos_type sp,
      ios_base::openmode which =
          ios_base::in | ios_base::out);
    int      pubsync();

    // Get and put areas:
    // 27.96.0.2.3 Get area:
    streamsize in_avail();
    int_type snextc();
    int_type sbumpc();
    int_type sgetc();
    streamsize sgetn(char_type* s, streamsize n);

    // 27.96.0.2.4 Putback:
    int_type sputbackc(char_type c);
```

```
    int_type sungetc();

    // 27.97.0.0.1 Put area:
    int_type   sputc(char_type c);
    streamsize sputn(const char_type* s, streamsize n);

  protected:
    basic_streambuf();
    basic_streambuf(const basic_streambuf& rhs);
    basic_streambuf& operator=(const basic_streambuf& rhs);

    void swap(basic_streambuf& rhs);

    // 27.99.0.1.2 Get area:
    char_type* eback() const;
    char_type* gptr()  const;
    char_type* egptr() const;
    void       gbump(int n);
    void       setg(char_type* gbeg, char_type* gnext, char_type* gend);

    // 27.99.0.1.3 Put area:
    char_type* pbase() const;
    char_type* pptr() const;
    char_type* epptr() const;
    void       pbump(int n);
    void       setp(char_type* pbeg, char_type* pend);

    // 27.99.0.2 virtual functions:
    // 27.99.0.2.1 Locales:
    virtual void imbue(const locale& loc);

    // 27.99.0.2.2 Buffer management and positioning:
    virtual basic_streambuf<char_type,traits>*
         setbuf(char_type* s, streamsize n);
    virtual pos_type seekoff(off_type off, ios_base::seekdir way,
        ios_base::openmode which = ios_base::in | ios_base::out);
    virtual pos_type seekpos(pos_type sp,
        ios_base::openmode which = ios_base::in | ios_base::out);
    virtual int      sync();

    // 27.101.0.0.1 Get area:
    virtual streamsize showmanyc();
    virtual streamsize xsgetn(char_type* s, streamsize n);
    virtual int_type   underflow();
    virtual int_type   uflow();

    // 27.102.0.0.1 Putback:
    virtual int_type   pbackfail(int_type c = traits::eof());

    // 27.103.0.0.1 Put area:
    virtual streamsize xsputn(const char_type* s, streamsize n);
    virtual int_type   overflow (int_type c = traits::eof());
  };
}
```

1

The class template `basic_streambuf<charT,traits>` serves as an abstract base class for deriving various *stream buffers* whose objects each control two *character sequences*:

— a character *input sequence*;

— a character *output sequence*.

27.96.0.1 `basic_streambuf` constructors [streambuf.cons]

`basic_streambuf();`

1 *Effects:* Constructs an object of class `basic_streambuf<charT,traits>` and initializes:[305]

(1.1) — all its pointer member objects to null pointers,

(1.2) — the `getloc()` member to a copy the global locale, `locale()`, at the time of construction.

2 *Remarks:* Once the `getloc()` member is initialized, results of calling locale member functions, and of members of facets so obtained, can safely be cached until the next time the member `imbue` is called.

`basic_streambuf(const basic_streambuf& rhs);`

3 *Effects:* Constructs a copy of `rhs`.

4 *Postconditions:*

(4.1) — `eback() == rhs.eback()`

(4.2) — `gptr() == rhs.gptr()`

(4.3) — `egptr() == rhs.egptr()`

(4.4) — `pbase() == rhs.pbase()`

(4.5) — `pptr() == rhs.pptr()`

(4.6) — `epptr() == rhs.epptr()`

(4.7) — `getloc() == rhs.getloc()`

`~basic_streambuf();`

5 *Effects:* None.

27.96.0.2 `basic_streambuf` public member functions [streambuf.members]

27.96.0.2.1 Locales [streambuf.locales]

`locale pubimbue(const locale& loc);`

1 *Postcondition:* `loc == getloc()`.

2 *Effects:* Calls `imbue(loc)`.

3 *Returns:* Previous value of `getloc()`.

`locale getloc() const;`

4 *Returns:* If `pubimbue()` has ever been called, then the last value of `loc` supplied, otherwise the current global locale, `locale()`, in effect at the time of construction. If called after `pubimbue()` has been called but before `pubimbue` has returned (i.e., from within the call of `imbue()`) then it returns the previous value.

305) The default constructor is protected for class `basic_streambuf` to assure that only objects for classes derived from this class may be constructed.

27.96.0.2.2 Buffer management and positioning [streambuf.buffer]

```
basic_streambuf<char_type,traits>* pubsetbuf(char_type* s, streamsize n);
```

1 *Returns:* `setbuf(s, n)`.

```
pos_type pubseekoff(off_type off, ios_base::seekdir way,
               ios_base::openmode which = ios_base::in | ios_base::out);
```

2 *Returns:* `seekoff(off, way, which)`.

```
pos_type pubseekpos(pos_type sp,
               ios_base::openmode which = ios_base::in | ios_base::out);
```

3 *Returns:* `seekpos(sp, which)`.

```
int pubsync();
```

4 *Returns:* `sync()`.

27.96.0.2.3 Get area [streambuf.pub.get]

```
streamsize in_avail();
```

1 *Returns:* If a read position is available, returns `egptr() - gptr()`. Otherwise returns `showmanyc()` (27.101.0.0.1).

```
int_type snextc();
```

2 *Effects:* Calls `sbumpc()`.

3 *Returns:* If that function returns `traits::eof()`, returns `traits::eof()`. Otherwise, returns `sgetc()`.

```
int_type sbumpc();
```

4 *Returns:* If the input sequence read position is not available, returns `uflow()`. Otherwise, returns `traits::to_int_type(*gptr())` and increments the next pointer for the input sequence.

```
int_type sgetc();
```

5 *Returns:* If the input sequence read position is not available, returns `underflow()`. Otherwise, returns `traits::to_int_type(*gptr())`.

```
streamsize sgetn(char_type* s, streamsize n);
```

6 *Returns:* `xsgetn(s, n)`.

27.96.0.2.4 Putback [streambuf.pub.pback]

```
int_type sputbackc(char_type c);
```

1 *Returns:* If the input sequence putback position is not available, or if `traits::eq(c,gptr()[-1])` is false, returns `pbackfail(traits::to_int_type(c))`. Otherwise, decrements the next pointer for the input sequence and returns `traits::to_int_type(*gptr())`.

```
int_type sungetc();
```

2

Returns: If the input sequence putback position is not available, returns `pbackfail()`. Otherwise, decrements the next pointer for the input sequence and returns `traits::to_int_type(*gptr())`.

27.97.0.0.1 Put area [streambuf.pub.put]

```
int_type sputc(char_type c);
```

1 *Returns:* If the output sequence write position is not available, returns `overflow(traits::to_int_type(c))`. Otherwise, stores `c` at the next pointer for the output sequence, increments the pointer, and returns `traits::to_int_type(c)`.

```
streamsize sputn(const char_type* s, streamsize n);
```

1 *Returns:* `xsputn(s,n)`.

27.99.0.1 basic_streambuf protected member functions [streambuf.protected]

27.99.0.1.1 Assignment [streambuf.assign]

```
basic_streambuf& operator=(const basic_streambuf& rhs);
```

1 *Effects:* Assigns the data members of `rhs` to `*this`.

2 *Postconditions:*

(2.1) — `eback() == rhs.eback()`

(2.2) — `gptr() == rhs.gptr()`

(2.3) — `egptr() == rhs.egptr()`

(2.4) — `pbase() == rhs.pbase()`

(2.5) — `pptr() == rhs.pptr()`

(2.6) — `epptr() == rhs.epptr()`

(2.7) — `getloc() == rhs.getloc()`

3 *Returns:* `*this`.

```
void swap(basic_streambuf& rhs);
```

4 *Effects:* Swaps the data members of `rhs` and `*this`.

27.99.0.1.2 Get area access [streambuf.get.area]

```
char_type* eback() const;
```

1 *Returns:* The beginning pointer for the input sequence.

```
char_type* gptr() const;
```

2 *Returns:* The next pointer for the input sequence.

```
char_type* egptr() const;
```

3 *Returns:* The end pointer for the input sequence.

```
void gbump(int n);
```

4 *Effects:* Adds `n` to the next pointer for the input sequence.

```
void setg(char_type* gbeg, char_type* gnext, char_type* gend);
```

5 *Postconditions:* `gbeg == eback()`, `gnext == gptr()`, and `gend == egptr()`.

27.99.0.1.3 Put area access [streambuf.put.area]

```
char_type* pbase() const;
```

1 *Returns:* The beginning pointer for the output sequence.

```
char_type* pptr() const;
```

2 *Returns:* The next pointer for the output sequence.

```
char_type* epptr() const;
```

3 *Returns:* The end pointer for the output sequence.

```
void pbump(int n);
```

4 *Effects:* Adds `n` to the next pointer for the output sequence.

```
void setp(char_type* pbeg, char_type* pend);
```

5 *Postconditions:* `pbeg == pbase()`, `pbeg == pptr()`, and `pend == epptr()`.

27.99.0.2 `basic_streambuf` virtual functions [streambuf.virtuals]

27.99.0.2.1 Locales [streambuf.virt.locales]

```
void imbue(const locale&);
```

1 *Effects:* Change any translations based on locale.

2 *Remarks:* Allows the derived class to be informed of changes in locale at the time they occur. Between invocations of this function a class derived from streambuf can safely cache results of calls to locale functions and to members of facets so obtained.

3 *Default behavior:* Does nothing.

27.99.0.2.2 Buffer management and positioning [streambuf.virt.buffer]

```
basic_streambuf* setbuf(char_type* s, streamsize n);
```

1

Effects: Influences stream buffering in a way that is defined separately for each class derived from `basic_streambuf` in this Clause (27.246.0.1, 27.288.0.1).

1 *Default behavior:* Does nothing. Returns `this`.

```
pos_type seekoff(off_type off, ios_base::seekdir way,
                 ios_base::openmode which
                  = ios_base::in | ios_base::out);
```

2 *Effects:* Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from `basic_streambuf` in this Clause (27.246.0.1, 27.288.0.1).

3 *Default behavior:* Returns `pos_type(off_type(-1))`.

```
pos_type seekpos(pos_type sp,
                 ios_base::openmode which
                  = ios_base::in | ios_base::out);
```

4 *Effects:* Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from `basic_streambuf` in this Clause (27.243.2, 27.248.1.1).

5 *Default behavior:* Returns `pos_type(off_type(-1))`.

```
int sync();
```

6 *Effects:* Synchronizes the controlled sequences with the arrays. That is, if `pbase()` is non-null the characters between `pbase()` and `pptr()` are written to the controlled sequence. The pointers may then be reset as appropriate.

7 *Returns:*-1 on failure. What constitutes failure is determined by each derived class (27.288.0.1).

8 *Default behavior:* Returns zero.

27.101.0.0.1 Get area [streambuf.virt.get]

```
streamsize showmanyc();
```[306]

1

Returns: An estimate of the number of characters available in the sequence, or -1. If it returns a positive value, then successive calls to `underflow()` will not return `traits::eof()` until at least that number of characters have been extracted from the stream. If `showmanyc()` returns -1, then calls to `underflow()` or `uflow()` will fail.[307]

1 *Default behavior:* Returns zero.

2 *Remarks:* Uses `traits::eof()`.

```
streamsize xsgetn(char_type* s, streamsize n);
```

3 *Effects:* Assigns up to `n` characters to successive elements of the array whose first element is designated by `s`. The characters assigned are read from the input sequence as if by repeated calls to `sbumpc()`. Assigning stops when either `n` characters have been assigned or a call to `sbumpc()` would return `traits::eof()`.

4 *Returns:* The number of characters assigned.[308]

5 *Remarks:* Uses `traits::eof()`.

```
int_type underflow();
```

6 *Remarks:* The public members of `basic_streambuf` call this virtual function only if `gptr()` is null or `gptr() >= egptr()`

7 *Returns:* `traits::to_int_type(c)`, where `c` is the first *character* of the *pending sequence*, without moving the input sequence position past it. If the pending sequence is null then the function returns `traits::eof()` to indicate failure.

8 The *pending sequence* of characters is defined as the concatenation of:

a) If `gptr()` is non-null, then the `egptr() - gptr()` characters starting at `gptr()`, otherwise the empty sequence.

b) Some sequence (possibly empty) of characters read from the input sequence.

9 The *result character* is

a) If the pending sequence is non-empty, the first character of the sequence.

b) If the pending sequence is empty then the next character that would be read from the input sequence.

306) The morphemes of `showmanyc` are "es-how-many-see", not "show-manic".
307) `underflow` or `uflow` might fail by throwing an exception prematurely. The intention is not only that the calls will not return `eof()` but that they will return "immediately."
308) Classes derived from `basic_streambuf` can provide more efficient ways to implement `xsgetn()` and `xsputn()` by overriding these definitions from the base class.

10 The *backup sequence* is defined as the concatenation of:

a) If `eback()` is null then empty,
b) Otherwise the `gptr() - eback()` characters beginning at `eback()`.

11 *Effects:* The function sets up the `gptr()` and `egptr()` satisfying one of:

a) If the pending sequence is non-empty, `egptr()` is non-null and `egptr() - gptr()` characters starting at `gptr()` are the characters in the pending sequence
b) If the pending sequence is empty, either `gptr()` is null or `gptr()` and `egptr()` are set to the same non-null pointer value.

12 If `eback()` and `gptr()` are non-null then the function is not constrained as to their contents, but the "usual backup condition" is that either:

a) If the backup sequence contains at least `gptr() - eback()` characters, then the `gptr() - eback()` characters starting at `eback()` agree with the last `gptr() - eback()` characters of the backup sequence.
b) Or the `n` characters starting at `gptr() - n` agree with the backup sequence (where `n` is the length of the backup sequence)

13 *Default behavior:* Returns `traits::eof()`.

```
int_type uflow();
```

14 *Requires:* The constraints are the same as for `underflow()`, except that the result character shall be transferred from the pending sequence to the backup sequence, and the pending sequence shall not be empty before the transfer.

15 *Default behavior:* Calls `underflow()`. If `underflow()` returns `traits::eof()`, returns `traits::eof()`. Otherwise, returns the value of `traits::to_int_type(*gptr())` and increment the value of the next pointer for the input sequence.

16 *Returns:* `traits::eof()` to indicate failure.

27.102.0.0.1 Putback [streambuf.virt.pback]

```
int_type pbackfail(int_type c = traits::eof());
```

1

Remarks: The public functions of `basic_streambuf` call this virtual function only when `gptr()` is null, `gptr() == eback()`, or `traits::eq(traits::to_char_type(c),gptr()[-1])` returns `false`. Other calls shall also satisfy that constraint.

The *pending sequence* is defined as for `underflow()`, with the modifications that

— If `traits::eq_int_type(c,traits::eof())` returns `true`, then the input sequence is backed up one character before the pending sequence is determined.
— If `traits::eq_int_type(c,traits::eof())` returns `false`, then `c` is prepended. Whether the input sequence is backed up or modified in any other way is unspecified.

1 *Postcondition:* On return, the constraints of `gptr()`, `eback()`, and `pptr()` are the same as for `underflow()`.

2 *Returns:* `traits::eof()` to indicate failure. Failure may occur because the input sequence could not be backed up, or if for some other reason the pointers could not be set consistent with the constraints. `pbackfail()` is called only when put back has really failed.

3 Returns some value other than `traits::eof()` to indicate success.

4 *Default behavior:* Returns `traits::eof()`.

27.103.0.0.1 Put area [streambuf.virt.put]

```
streamsize xsputn(const char_type* s, streamsize n);
```

1 *Effects:* Writes up to `n` characters to the output sequence as if by repeated calls to `sputc(c)`. The characters written are obtained from successive elements of the array whose first element is designated by `s`. Writing stops when either `n` characters have been written or a call to `sputc(c)` would return `traits::eof()`. Is is unspecified whether the function calls `overflow()` when `pptr() == epptr()` becomes true or whether it achieves the same effects by other means.

2 *Returns:* The number of characters written.

```
int_type overflow(int_type c = traits::eof());
```

3 *Effects:* Consumes some initial subsequence of the characters of the *pending sequence*. The pending sequence is defined as the concatenation of

a) if `pbase()` is null then the empty sequence otherwise, `pptr() - pbase()` characters beginning at `pbase()`.

b) if `traits::eq_int_type(c,traits::eof())` returns `true`, then the empty sequence otherwise, the sequence consisting of `c`.

4 *Remarks:* The member functions `sputc()` and `sputn()` call this function in case that no room can be found in the put buffer enough to accommodate the argument character sequence.

5 *Requires:* Every overriding definition of this virtual function shall obey the following constraints:

1) The effect of consuming a character on the associated output sequence is specified[309]

2) Let `r` be the number of characters in the pending sequence not consumed. If `r` is non-zero then `pbase()` and `pptr()` shall be set so that: `pptr() - pbase() == r` and the `r` characters starting at `pbase()` are the associated output stream. In case `r` is zero (all characters of the pending sequence have been consumed) then either `pbase()` is set to `nullptr`, or `pbase()` and `pptr()` are both set to the same non-null value.

3) The function may fail if either appending some character to the associated output stream fails or if it is unable to establish `pbase()` and `pptr()` according to the above rules.

1 *Returns:* `traits::eof()` or throws an exception if the function fails.

Otherwise, returns some value other than `traits::eof()` to indicate success.[310]

1 *Default behavior:* Returns `traits::eof()`.

27.109 Formatting and manipulators [iostream.format]

27.109.1 Overview [iostream.format.overview]

Header `<istream>` synopsis

309) That is, for each class derived from an instance of `basic_streambuf` in this Clause (27.243.2, 27.248.1.1), a specification of how consuming a character effects the associated output sequence is given. There is no requirement on a program-defined class.

310) Typically, `overflow` returns `c` to indicate success, except when `traits::eq_int_type(c,traits::eof())` returns `true`, in which case it returns `traits::not_eof(c)`.

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
    class basic_istream;
  typedef basic_istream<char>     istream;

27.109.2 Input streams [input.streams]

1 The header `<istream>` defines two types and a function signature that control input from a stream buffer along with a function template that extracts from stream rvalues.

27.109.2.1 Class template `basic_istream` [istream]

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
  class basic_istream : virtual public basic_ios<charT,traits> {
  public:
    // types (inherited from basic_ios (27.78.2)):
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;

    // 27.116.0.0.1 Constructor/destructor:
    explicit basic_istream(basic_streambuf<charT,traits>* sb);
    virtual ~basic_istream();

    // 27.117.0.0.2 Prefix/suffix:
    class sentry;

    // 27.128.0.1 Formatted input:
    basic_istream<charT,traits>& operator>>(
      basic_istream<charT,traits>& (*pf)(basic_istream<charT,traits>&));
    basic_istream<charT,traits>& operator>>(
                       basic_ios<charT,traits>& (*pf)(basic_ios<charT,traits>&));
    basic_istream<charT,traits>& operator>>(
      ios_base& (*pf)(ios_base&));

    basic_istream<charT,traits>& operator>>(bool& n);
    basic_istream<charT,traits>& operator>>(short& n);
    basic_istream<charT,traits>& operator>>(unsigned short& n);
    basic_istream<charT,traits>& operator>>(int& n);
    basic_istream<charT,traits>& operator>>(unsigned int& n);
    basic_istream<charT,traits>& operator>>(long& n);
    basic_istream<charT,traits>& operator>>(unsigned long& n);
    basic_istream<charT,traits>& operator>>(long long& n);
    basic_istream<charT,traits>& operator>>(unsigned long long& n);
    basic_istream<charT,traits>& operator>>(float& f);
    basic_istream<charT,traits>& operator>>(double& f);
    basic_istream<charT,traits>& operator>>(long double& f);
```

```
  basic_istream<charT,traits>& operator>>(void*& p);
  basic_istream<charT,traits>& operator>>(
    basic_streambuf<char_type,traits>* sb);

  // 27.154.0.1 Unformatted input:
  streamsize gcount() const;
  int_type get();
  basic_istream<charT,traits>& get(char_type& c);
  basic_istream<charT,traits>& get(char_type* s, streamsize n);
  basic_istream<charT,traits>& get(char_type* s, streamsize n,
                                   char_type delim);
  basic_istream<charT,traits>& get(basic_streambuf<char_type,traits>& sb);
  basic_istream<charT,traits>& get(basic_streambuf<char_type,traits>& sb,
                                   char_type delim);

  basic_istream<charT,traits>& getline(char_type* s, streamsize n);
  basic_istream<charT,traits>& getline(char_type* s, streamsize n,
                                       char_type delim);

  basic_istream<charT,traits>& ignore(
    streamsize n = 1, int_type delim = traits::eof());
  int_type                     peek();
  basic_istream<charT,traits>& read    (char_type* s, streamsize n);
  streamsize                   readsome(char_type* s, streamsize n);

  basic_istream<charT,traits>& putback(char_type c);
  basic_istream<charT,traits>& unget();
  int sync();

  pos_type tellg();
  basic_istream<charT,traits>& seekg(pos_type);
  basic_istream<charT,traits>& seekg(off_type, ios_base::seekdir);

protected:
  basic_istream(const basic_istream& rhs) = delete;
  basic_istream(basic_istream&& rhs);

  // 27.117.0.0.1 Assign/swap:
  basic_istream& operator=(const basic_istream& rhs) = delete;
  basic_istream& operator=(basic_istream&& rhs);
  void swap(basic_istream& rhs);
};

// 27.141.0.0.1 character extraction templates:
template<class charT, class traits>
  basic_istream<charT,traits>& operator>>(basic_istream<charT,traits>&,
                                          charT&);
template<class traits>
  basic_istream<char,traits>& operator>>(basic_istream<char,traits>&,
                                         unsigned char&);
template<class traits>
  basic_istream<char,traits>& operator>>(basic_istream<char,traits>&,
                                         signed char&);

template<class charT, class traits>
```

```
    basic_istream<charT,traits>& operator>>(basic_istream<charT,traits>&,
                                            charT*);
  template<class traits>
    basic_istream<char,traits>& operator>>(basic_istream<char,traits>&,
                                           unsigned char*);
  template<class traits>
    basic_istream<char,traits>& operator>>(basic_istream<char,traits>&,
                                           signed char*);
}
```

1 The class `basic_istream` defines a number of member function signatures that assist in reading and interpreting input from sequences controlled by a stream buffer.

2

Two groups of member function signatures share common properties: the *formatted input functions* (or *extractors*) and the *unformatted input functions.* Both groups of input functions are described as if they obtain (or *extract*) input *characters* by calling `rdbuf()->sbumpc()` or `rdbuf()->sgetc()`. They may use other public members of `istream`.

1

If `rdbuf()->sbumpc()` or `rdbuf()->sgetc()` returns `traits::eof()`, then the input function, except as explicitly noted otherwise, completes its actions and does `setstate(eofbit)`, which may throw `ios_base::failure` (27.84.0.1), before returning.

1

If one of these called functions throws an exception, then unless explicitly noted otherwise, the input function sets `badbit` in error state. If `badbit` is on in `exceptions()`, the input function rethrows the exception without completing its actions, otherwise it does not throw anything and proceeds as if the called function had returned a failure indication.

27.116.0.0.1 `basic_istream` constructors [istream.cons]

`explicit basic_istream(basic_streambuf<charT,traits>* sb);`

1 *Effects:* Constructs an object of class `basic_istream`, assigning initial values to the base class by calling `basic_ios::init(sb)` (27.78.2.2).

2 *Postcondition:* `gcount() == 0`

`basic_istream(basic_istream&& rhs);`

3 *Effects:* Move constructs from the rvalue `rhs`. This is accomplished by default constructing the base class, copying the `gcount()` from `rhs`, calling `basic_ios<charT, traits>::move(rhs)` to initialize the base class, and setting the `gcount()` for `rhs` to 0.

`virtual ~basic_istream();`

4 *Effects:* Destroys an object of class `basic_istream`.

5

Remarks: Does not perform any operations of `rdbuf()`.

27.117.0.0.1 Class `basic_istream` assign and swap [istream.assign]

`basic_istream& operator=(basic_istream&& rhs);`

1 *Effects:* `swap(rhs);`.

2 *Returns:* `*this`.

```
void swap(basic_istream& rhs);
```

3 *Effects:* Calls `basic_ios<charT, traits>::swap(rhs)`. Exchanges the values returned by `gcount()` and `rhs.gcount()`.

27.117.0.0.2 Class `basic_istream::sentry` [istream::sentry]

```
namespace std {
  template <class charT,class traits = char_traits<charT> >
  class basic_istream<charT,traits>::sentry {
    typedef traits traits_type;
    bool ok_; // exposition only
  public:
    explicit sentry(basic_istream<charT,traits>& is, bool noskipws = false);
    ~sentry();
    explicit operator bool() const { return ok_; }
    sentry(const sentry&) = delete;
    sentry& operator=(const sentry&) = delete;
  };
}
```

1 The class `sentry` defines a class that is responsible for doing exception safe prefix and suffix operations.

```
explicit sentry(basic_istream<charT,traits>& is, bool noskipws = false);
```

1 *Effects:* If `is.good()` is `false`, calls `is.setstate(failbit)`. Otherwise, prepares for formatted or unformatted input. First, if `is.tie()` is not a null pointer, the function calls `is.tie()->flush()` to synchronize the output sequence with any associated external C stream. Except that this call can be suppressed if the put area of `is.tie()` is empty. Further an implementation is allowed to defer the call to `flush` until a call of `is.rdbuf()->underflow()` occurs. If no such call occurs before the `sentry` object is destroyed, the call to `flush` may be eliminated entirely.[311] If `noskipws` is zero and `is.flags() & ios_base::skipws` is nonzero, the function extracts and discards each character as long as the next available input character `c` is a whitespace character. If `is.rdbuf()->sbumpc()` or `is.rdbuf()->sgetc()` returns `traits::eof()`, the function calls `setstate(failbit | eofbit)` (which may throw `ios_base::failure`).

1 *Remarks:* The constructor `explicit sentry(basic_istream<charT,traits>& is, bool noskipws = false)` uses the currently imbued locale in `is`, to determine whether the next input character is whitespace or not.

2 To decide if the character `c` is a whitespace character, the constructor performs as if it executes the following code fragment:

```
const ctype<charT>& ctype = use_facet<ctype<charT> >(is.getloc());
if (ctype.is(ctype.space,c)!=0)
  // c is a whitespace character.
```

3 If, after any preparation is completed, `is.good()` is `true`, `ok_ != false` otherwise, `ok_ == false`. During preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure` (27.84.0.1))[312]

311) This will be possible only in functions that are part of the library. The semantics of the constructor used in user code is as specified.

312) The sentry constructor and destructor can also perform additional implementation-dependent operations.

```
~sentry();
```

4

Effects: None.

```
explicit operator bool() const;
```

1 *Effects:* Returns `ok_`.

27.128.0.1 Formatted input functions [istream.formatted]

27.128.0.1.1 Common requirements [istream.formatted.reqmts]

1

Each formatted input function begins execution by constructing an object of class `sentry` with the `noskipws` (second) argument `false`. If the `sentry` object returns `true`, when converted to a value of type `bool`, the function endeavors to obtain the requested input. If an exception is thrown during input then `ios::badbit` is turned on[313] in `*this`'s error state. If `(exceptions()&badbit) != 0` then the exception is rethrown. In any case, the formatted input function destroys the `sentry` object. If no exception has been thrown, it returns `*this`.

27.132.0.0.1 Arithmetic extractors [istream.formatted.arithmetic]

```
operator>>(unsigned short& val);
operator>>(unsigned int& val);
operator>>(long& val);
operator>>(unsigned long& val);
operator>>(long long& val);
operator>>(unsigned long long& val);
operator>>(float& val);
operator>>(double& val);
operator>>(long double& val);
operator>>(bool& val);
operator>>(void*& val);
```

1

As in the case of the inserters, these extractors depend on the locale's `num_get<>` (22.45.0.1) object to perform parsing the input stream data. These extractors behave as formatted input functions (as described in 27.128.0.1.1). After a sentry object is constructed, the conversion occurs as if performed by the following code fragment:

```
typedef num_get< charT,istreambuf_iterator<charT,traits> > numget;
iostate err = iostate::goodbit;
use_facet< numget >(loc).get(*this, 0, *this, err, val);
setstate(err);
```

In the above fragment, `loc` stands for the private member of the `basic_ios` class. [*Note:* The first argument provides an object of the `istreambuf_iterator` class which is an iterator pointed to an input stream. It bypasses istreams and uses streambufs directly. — *end note*] Class `locale` relies on this type as its interface to `istream`, so that it does not need to depend directly on `istream`.

```
operator>>(short& val);
```

1

The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

313) This is done without causing an `ios::failure` to be thrown.

```
typedef num_get<charT,istreambuf_iterator<charT,traits> > numget;
iostate err = ios_base::goodbit;
long lval;
use_facet<numget>(loc).get(*this, 0, *this, err, lval);
if (lval < numeric_limits<short>::min()) {
  err |= ios_base::failbit;
  val = numeric_limits<short>::min();
} else if (numeric_limits<short>::max() < lval) {
  err |= ios_base::failbit;
  val = numeric_limits<short>::max();
}  else
  val = static_cast<short>(lval);
setstate(err);
```

`operator>>(int& val);`

1 The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```
typedef num_get<charT,istreambuf_iterator<charT,traits> > numget;
iostate err = ios_base::goodbit;
long lval;
use_facet<numget>(loc).get(*this, 0, *this, err, lval);
if (lval < numeric_limits<int>::min()) {
  err |= ios_base::failbit;
  val = numeric_limits<int>::min();
} else if (numeric_limits<int>::max() < lval) {
  err |= ios_base::failbit;
  val = numeric_limits<int>::max();
}  else
  val = static_cast<int>(lval);
setstate(err);
```

27.141.0.0.1 `basic_istream::operator>>` [istream::extractors]

`basic_istream<charT,traits>& operator>>`
`(basic_istream<charT,traits>& (*pf)(basic_istream<charT,traits>&));`

1 *Effects:* None. This extractor does not behave as a formatted input function (as described in 27.128.0.1.1.)

2 *Returns:* `pf(*this)`.[314]

`basic_istream<charT,traits>& operator>>`
`(basic_ios<charT,traits>& (*pf)(basic_ios<charT,traits>&));`

3 *Effects:* Calls `pf(*this)`. This extractor does not behave as a formatted input function (as described in 27.128.0.1.1).

4 *Returns:* `*this`.

`basic_istream<charT,traits>& operator>>`
`(ios_base& (*pf)(ios_base&));`

5 *Effects:* Calls `pf(*this)`.[315] This extractor does not behave as a formatted input function (as described in 27.128.0.1.1).

6 *Returns:* `*this`.

314) See, for example, the function signature `ws(basic_istream&)` (27.184.0.1).
315) See, for example, the function signature `dec(ios_base&)` (27.91.1.3).

```
template<class charT, class traits>
  basic_istream<charT,traits>& operator>>(basic_istream<charT,traits>& in,
                                          charT* s);
template<class traits>
  basic_istream<char,traits>& operator>>(basic_istream<char,traits>& in,
                                         unsigned char* s);
template<class traits>
  basic_istream<char,traits>& operator>>(basic_istream<char,traits>& in,
                                         signed char* s);
```

7 *Effects:* Behaves like a formatted input member (as described in 27.128.0.1.1) of `in`. After a `sentry` object is constructed, `operator>>` extracts characters and stores them into successive locations of an array whose first element is designated by `s`. If `width()` is greater than zero, `n` is `width()`. Otherwise `n` is the number of elements of the largest array of `char_type` that can store a terminating `charT()`. `n` is the maximum number of characters stored.

8 Characters are extracted and stored until any of the following occurs:

— `n-1` characters are stored;

— end of file occurs on the input sequence;

— `ct.is(ct.space,c)` is `true` for the next available input character `c`, where `ct` is `use_facet<ctype< charT> >(in.getloc())`.

1 `operator>>` then stores a null byte (`charT()`) in the next position, which may be the first position if no characters were extracted. `operator>>` then calls `width(0)`.

1 If the function extracted no characters, it calls `setstate(failbit)`, which may throw `ios_base::failure` (27.84.0.1).

2 *Returns:* `in`.

```
template<class charT, class traits>
  basic_istream<charT,traits>& operator>>(basic_istream<charT,traits>& in,
                                          charT& c);
template<class traits>
  basic_istream<char,traits>& operator>>(basic_istream<char,traits>& in,
                                         unsigned char& c);
template<class traits>
  basic_istream<char,traits>& operator>>(basic_istream<char,traits>& in,
                                         signed char& c);
```

3 *Effects:* Behaves like a formatted input member (as described in 27.128.0.1.1) of `in`. After a `sentry` object is constructed a character is extracted from `in`, if one is available, and stored in `c`. Otherwise, the function calls `in.setstate(failbit)`.

1 *Returns:* `in`.

```
basic_istream<charT,traits>& operator>>
  (basic_streambuf<charT,traits>* sb);
```

2 *Effects:* Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1). If `sb` is null, calls `setstate(failbit)`, which may throw `ios_base::failure` (27.84.0.1). After a sentry

object is constructed, extracts characters from `*this` and inserts them in the output sequence controlled by `sb`. Characters are extracted and inserted until any of the following occurs:

— end-of-file occurs on the input sequence;

— inserting in the output sequence fails (in which case the character to be inserted is not extracted);

— an exception occurs (in which case the exception is caught).

1

If the function inserts no characters, it calls `setstate(failbit)`, which may throw `ios_base::failure` (27.84.0.1). If it inserted no characters because it caught an exception thrown while extracting characters from `*this` and `failbit` is on in `exceptions()` (27.84.0.1), then the caught exception is rethrown.

1 *Returns:* `*this`.

27.154.0.1 Unformatted input functions [istream.unformatted]

1

Each unformatted input function begins execution by constructing an object of class `sentry` with the default argument `noskipws` (second) argument `true`. If the `sentry` object returns `true`, when converted to a value of type `bool`, the function endeavors to obtain the requested input. Otherwise, if the sentry constructor exits by throwing an exception or if the sentry object returns false, when converted to a value of type `bool`, the function returns without attempting to obtain any input. In either case the number of extracted characters is set to 0; unformatted input functions taking a character array of non-zero size as an argument shall also store a null character (using `charT()`) in the first location of the array. If an exception is thrown during input then `ios::badbit` is turned on[316] in `*this`'s error state. (Exceptions thrown from `basic_ios<>::clear()` are not caught or rethrown.) If `(exceptions()&badbit) != 0` then the exception is rethrown. It also counts the number of characters extracted. If no exception has been thrown it ends by storing the count in a member object and returning the value specified. In any event the `sentry` object is destroyed before leaving the unformatted input function.

```
streamsize gcount() const;
```

1

Effects: None. This member function does not behave as an unformatted input function (as described in 27.154.0.1, paragraph 1).

1 *Returns:* The number of characters extracted by the last unformatted input member function called for the object.

```
int_type get();
```

2

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1). After constructing a sentry object, extracts a character `c`, if one is available. Otherwise, the function calls `setstate(failbit)`, which may throw `ios_base::failure` (27.84.0.1),

1 *Returns:* `c` if available, otherwise `traits::eof()`.

```
basic_istream<charT,traits>& get(char_type& c);
```

316) This is done without causing an `ios::failure` to be thrown.

2

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1). After constructing a sentry object, extracts a character, if one is available, and assigns it to `c`.[317] Otherwise, the function calls `setstate(failbit)` (which may throw `ios_base::failure` (27.84.0.1)).

1 *Returns:* `*this`.

```
basic_istream<charT,traits>& get(char_type* s, streamsize n,
                  char_type delim );
```

2

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1). After constructing a sentry object, extracts characters and stores them into successive locations of an array whose first element is designated by `s`.[318] Characters are extracted and stored until any of the following occurs:

— `n` is less than one or `n - 1` characters are stored;

— end-of-file occurs on the input sequence (in which case the function calls `setstate(eofbit)`);

— `traits::eq(c, delim)` for the next available input character `c` (in which case `c` is not extracted).

1 If the function stores no characters, it calls `setstate(failbit)` (which may throw `ios_base::failure` (27.84.0.1)). In any case, if `n` is greater than zero it then stores a null character into the next successive location of the array.

2 *Returns:* `*this`.

```
basic_istream<charT,traits>& get(char_type* s, streamsize n);
```

3 *Effects:* Calls `get(s,n,widen('\n'))`

4 *Returns:* Value returned by the call.

```
basic_istream<charT,traits>& get(basic_streambuf<char_type,traits>& sb,
                  char_type delim );
```

5 *Effects:* Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1). After constructing a sentry object, extracts characters and inserts them in the output sequence controlled by `sb`. Characters are extracted and inserted until any of the following occurs:

(5.1) — end-of-file occurs on the input sequence;

(5.2) — inserting in the output sequence fails (in which case the character to be inserted is not extracted);

(5.3) — `traits::eq(c, delim)` for the next available input character `c` (in which case `c` is not extracted);

(5.4) — an exception occurs (in which case, the exception is caught but not rethrown).

6 If the function inserts no characters, it calls `setstate(failbit)`, which may throw `ios_base::failure` (27.84.0.1).

7 *Returns:* `*this`.

```
basic_istream<charT,traits>& get(basic_streambuf<char_type,traits>& sb);
```

8 *Effects:* Calls `get(sb, widen('\n'))`

9 *Returns:* Value returned by the call.

317) Note that this function is not overloaded on types `signed char` and `unsigned char`.
318) Note that this function is not overloaded on types `signed char` and `unsigned char`.

```
basic_istream<charT,traits>& getline(char_type* s, streamsize n,
                      char_type delim);
```

10

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1). After constructing a sentry object, extracts characters and stores them into successive locations of an array whose first element is designated by `s`.[319] Characters are extracted and stored until one of the following occurs:

1. end-of-file occurs on the input sequence (in which case the function calls `setstate(eofbit)`);
2. `traits::eq(c, delim)` for the next available input character `c` (in which case the input character is extracted but not stored);[320]
3. `n` is less than one or `n - 1` characters are stored (in which case the function calls `setstate(failbit)`).

1 These conditions are tested in the order shown.[321]

2 If the function extracts no characters, it calls `setstate(failbit)` (which may throw `ios_base::failure` (27.84.0.1)).[322]

3 In any case, if `n` is greater than zero, it then stores a null character (using `charT()`) into the next successive location of the array.

4 *Returns:* `*this`.

5 [*Example:*

```
#include <iostream>

int main() {
  using namespace std;
  const int line_buffer_size = 100;

  char buffer[line_buffer_size];
  int line_number = 0;
  while (cin.getline(buffer, line_buffer_size, '\n') || cin.gcount()) {
    int count = cin.gcount();
    if (cin.eof())
      cout << "Partial final line";   // cin.fail() is false
    else if (cin.fail()) {
      cout << "Partial long line";
      cin.clear(cin.rdstate() & ~ios_base::failbit);
    } else {
      count--;                        // Don't include newline in count
      cout << "Line " << ++line_number;
    }
    cout << " (" << count << " chars): " << buffer << endl;
  }
}
```

— *end example*]

319) Note that this function is not overloaded on types `signed char` and `unsigned char`.
320) Since the final input character is "extracted," it is counted in the `gcount()`, even though it is not stored.
321) This allows an input line which exactly fills the buffer, without setting `failbit`. This is different behavior than the historical AT&T implementation.
322) This implies an empty input line will not cause `failbit` to be set.

```
basic_istream<charT,traits>& getline(char_type* s, streamsize n);
```

6 *Returns:* `getline(s,n,widen('\n'))`

```
basic_istream<charT,traits>&
    ignore(streamsize n = 1, int_type delim = traits::eof());
```

7

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1). After constructing a sentry object, extracts characters and discards them. Characters are extracted until any of the following occurs:

— `n != numeric_limits<streamsize>::max()` (18.41.2) and `n` characters have been extracted so far

— end-of-file occurs on the input sequence (in which case the function calls `setstate(eofbit)`, which may throw `ios_base::failure` (27.84.0.1));

— `traits::eq_int_type(traits::to_int_type(c), delim)` for the next available input character `c` (in which case `c` is extracted).

1 *Remarks:* The last condition will never occur if `traits::eq_int_type(delim, traits::eof())`.

2 *Returns:* `*this`.

```
int_type peek();
```

3 *Effects:* Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1). After constructing a sentry object, reads but does not extract the current input character.

4 *Returns:* `traits::eof()` if `good()` is `false`. Otherwise, returns `rdbuf()->sgetc()`.

```
basic_istream<charT,traits>& read(char_type* s, streamsize n);
```

5

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1). After constructing a sentry object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. Otherwise extracts characters and stores them into successive locations of an array whose first element is designated by `s`.[323] Characters are extracted and stored until either of the following occurs:

— `n` characters are stored;

— end-of-file occurs on the input sequence (in which case the function calls `setstate(failbit | eofbit)`, which may throw `ios_base::failure` (27.84.0.1)).

1 *Returns:* `*this`.

```
streamsize readsome(char_type* s, streamsize n);
```

2

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1). After constructing a sentry object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. Otherwise extracts characters and stores them into successive locations of an array whose first element is designated by `s`. If `rdbuf()->in_avail() == -1`, calls `setstate(eofbit)` (which may throw `ios_base::failure` (27.84.0.1)), and extracts no characters;

— If `rdbuf()->in_avail() == 0`, extracts no characters

323) Note that this function is not overloaded on types `signed char` and `unsigned char`.

— If `rdbuf()->in_avail() > 0`, extracts `min(rdbuf()->in_avail(),n))`.

1 *Returns:* The number of characters extracted.

`basic_istream<charT,traits>& putback(char_type c);`

2

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1), except that the function first clears `eofbit`. After constructing a sentry object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. If `rdbuf()` is not null, calls `rdbuf->sputbackc()`. If `rdbuf()` is null, or if `sputbackc()` returns `traits::eof()`, calls `setstate(badbit)` (which may throw `ios_base::failure` (27.84.0.1)). [*Note:* This function extracts no characters, so the value returned by the next call to `gcount()` is 0. — *end note*]

1 *Returns:* `*this`.

`basic_istream<charT,traits>& unget();`

2

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1), except that the function first clears `eofbit`. After constructing a sentry object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. If `rdbuf()` is not null, calls `rdbuf()->sungetc()`. If `rdbuf()` is null, or if `sungetc()` returns `traits::eof()`, calls `setstate(badbit)` (which may throw `ios_base::failure` (27.84.0.1)). [*Note:* This function extracts no characters, so the value returned by the next call to `gcount()` is 0. — *end note*]

1 *Returns:* `*this`.

`int sync();`

2 *Effects:* Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to `gcount()`. After constructing a sentry object, if `rdbuf()` is a null pointer, returns -1 . Otherwise, calls `rdbuf()->pubsync()` and, if that function returns -1 calls `setstate(badbit)` (which may throw `ios_base::failure` (27.84.0.1), and returns `-1`. Otherwise, returns zero.

`pos_type tellg();`

3 *Effects:* Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to `gcount()`.

4

Returns: After constructing a sentry object, if `fail() != false`, returns `pos_type(-1)` to indicate failure. Otherwise, returns `rdbuf()->pubseekoff(0, cur, in)`.

`basic_istream<charT,traits>& seekg(pos_type pos);`

1

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1), except that the function first clears `eofbit`, it does not count the number of characters extracted, and it does not affect the value returned by subsequent calls to `gcount()`. After constructing a sentry object, if `fail() != true`, executes `rdbuf()->pubseekpos(pos, ios_base::in)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

1 *Returns:* `*this`.

```
basic_istream<charT,traits>& seekg(off_type off, ios_base::seekdir dir);
```

2

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to `gcount()`. After constructing a sentry object, if `fail() != true`, executes `rdbuf()->pubseekoff(off, dir, ios_base::in)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

1 *Returns:* `*this`.

27.184.0.1 Standard `basic_istream` manipulators [istream.manip]

```
namespace std {
  template <class charT, class traits>
    basic_istream<charT,traits>& ws(basic_istream<charT,traits>& is);
}
```

1

Effects: Behaves as an unformatted input function (as described in 27.154.0.1, paragraph 1), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to is.gcount(). After constructing a sentry object extracts characters as long as the next available character `c` is whitespace or until there are no more characters in the sequence. Whitespace characters are distinguished with the same criterion as used by `sentry::sentry` (27.117.0.0.2). If `ws` stops extracting characters because there are no more available it sets `eofbit`, but not `failbit`.

1 *Returns:* `is`.

27.186.0.1 Class template `basic_iostream` [iostreamclass]

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
  class basic_iostream :
    public basic_istream<charT,traits>,
    public basic_ostream<charT,traits> {
  public:
    // types:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;

    // constructor/destructor
    explicit basic_iostream(basic_streambuf<charT,traits>* sb);
    virtual ~basic_iostream();

  protected:
    basic_iostream(const basic_iostream& rhs) = delete;
    basic_iostream(basic_iostream&& rhs);

    // assign/swap
    basic_iostream& operator=(const basic_iostream& rhs) = delete;
    basic_iostream& operator=(basic_iostream&& rhs);
    void swap(basic_iostream& rhs);
  };
}
```

1 The class `basic_iostream` inherits a number of functions that allow reading input and writing output to sequences controlled by a stream buffer.

27.186.0.1.1 `basic_iostream` constructors [iostream.cons]

```
explicit basic_iostream(basic_streambuf<charT,traits>* sb);
```

1 *Effects:* Constructs an object of class `basic_iostream`, assigning initial values to the base classes by calling `basic_istream<charT,traits>(sb)` (27.109.2.1) and `basic_ostream<charT,traits>(sb)` (27.187.1.1)

2 *Postcondition:* `rdbuf()==sb` and `gcount()==0`.

```
basic_iostream(basic_iostream&& rhs);
```

3

Effects: Move constructs from the rvalue `rhs` by constructing the `basic_istream` base class with `move(rhs)`.

27.187.0.0.1 `basic_iostream` destructor [iostream.dest]

```
virtual ~basic_iostream();
```

1 *Effects:* Destroys an object of class `basic_iostream`.

2 *Remarks:* Does not perform any operations on `rdbuf()`.

27.187.0.0.2 `basic_iostream` assign and swap [iostream.assign]

```
basic_iostream& operator=(basic_iostream&& rhs);
```

1 *Effects:* `swap(rhs)`.

```
void swap(basic_iostream& rhs);
```

2 *Effects:* Calls `basic_istream<charT, traits>::swap(rhs)`.

27.187.0.1 Rvalue stream extraction [istream.rvalue]

```
template <class charT, class traits, class T>
  basic_istream<charT, traits>&
  operator>>(basic_istream<charT, traits>&& is, T& x);
```

1 *Effects:* `is >>x`

2 *Returns:* `is`

27.187.1 Output streams [output.streams]

1 The header `<ostream>` defines a type and several function signatures that control output to a stream buffer along with a function template that inserts into stream rvalues.

27.187.1.1 Class template `basic_ostream` [ostream]

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
  class basic_ostream : virtual public basic_ios<charT,traits> {
  public:
    // types (inherited from basic_ios (27.78.2)):
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
```

```
  typedef typename traits::off_type off_type;
  typedef traits                    traits_type;

  // 27.188.0.1 Constructor/destructor:
  explicit basic_ostream(basic_streambuf<char_type,traits>* sb);
  virtual ~basic_ostream();

  // 27.190.0.2 Prefix/suffix:
  class sentry;

  // 27.198.0.1 Formatted output:
  basic_ostream<charT,traits>& operator<<(
    basic_ostream<charT,traits>& (*pf)(basic_ostream<charT,traits>&));
  basic_ostream<charT,traits>& operator<<(
    basic_ios<charT,traits>& (*pf)(basic_ios<charT,traits>&));
  basic_ostream<charT,traits>& operator<<(
    ios_base& (*pf)(ios_base&));

  basic_ostream<charT,traits>& operator<<(bool n);
  basic_ostream<charT,traits>& operator<<(short n);
  basic_ostream<charT,traits>& operator<<(unsigned short n);
  basic_ostream<charT,traits>& operator<<(int n);
  basic_ostream<charT,traits>& operator<<(unsigned int n);
  basic_ostream<charT,traits>& operator<<(long n);
  basic_ostream<charT,traits>& operator<<(unsigned long n);
  basic_ostream<charT,traits>& operator<<(long long n);
  basic_ostream<charT,traits>& operator<<(unsigned long long n);
  basic_ostream<charT,traits>& operator<<(float f);
  basic_ostream<charT,traits>& operator<<(double f);
  basic_ostream<charT,traits>& operator<<(long double f);

  basic_ostream<charT,traits>& operator<<(const void* p);
  basic_ostream<charT,traits>& operator<<(
    basic_streambuf<char_type,traits>* sb);

  // 27.225.0.1 Unformatted output:
  basic_ostream<charT,traits>& put(char_type c);
  basic_ostream<charT,traits>& write(const char_type* s, streamsize n);

  basic_ostream<charT,traits>& flush();

  // 27.196.0.1 seeks:
  pos_type tellp();
  basic_ostream<charT,traits>& seekp(pos_type);
  basic_ostream<charT,traits>& seekp(off_type, ios_base::seekdir);
protected:
  basic_ostream(const basic_ostream& rhs) = delete;
  basic_ostream(basic_ostream&& rhs);

  // 27.190.0.1 Assign/swap
  basic_ostream& operator=(const basic_ostream& rhs) = delete;
  basic_ostream& operator=(basic_ostream&& rhs);
  void swap(basic_ostream& rhs);
};
```

```
  // 27.217.0.0.1 character inserters
  template<class charT, class traits>
    basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>&,
                                            charT);
  template<class charT, class traits>
    basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>&,
                                            char);
  template<class traits>
    basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>&,
                                           char);

  // signed and unsigned
  template<class traits>
    basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>&,
                                           signed char);
  template<class traits>
    basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>&,
                                           unsigned char);

  template<class charT, class traits>
    basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>&,
                                            const charT*);
  template<class charT, class traits>
    basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>&,
                                            const char*);
  template<class traits>
    basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>&,
                                           const char*);

  // signed and unsigned
  template<class traits>
    basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>&,
                                           const signed char*);
  template<class traits>
    basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>&,
                                           const unsigned char*);
}
```

1 The class `basic_ostream` defines a number of member function signatures that assist in formatting and writing output to output sequences controlled by a stream buffer.

2

Two groups of member function signatures share common properties: the *formatted output functions* (or *inserters*) and the *unformatted output functions.* Both groups of output functions generate (or *insert*) output *characters* by actions equivalent to calling `rdbuf()->sputc(int_type)`. They may use other public members of `basic_ostream` except that they shall not invoke any virtual members of `rdbuf()` except `overflow()`, `xsputn()`, and `sync()`.

1 If one of these called functions throws an exception, then unless explicitly noted otherwise the output function sets `badbit` in error state. If `badbit` is on in `exceptions()`, the output function rethrows the exception without completing its actions, otherwise it does not throw anything and treat as an error.

27.188.0.1 `basic_ostream` constructors [ostream.cons]

```
explicit basic_ostream(basic_streambuf<charT,traits>* sb);
```

1

Effects: Constructs an object of class `basic_ostream`, assigning initial values to the base class by calling `basic_ios<charT,traits>::init(sb)` (27.78.2.2).

1 *Postcondition:* `rdbuf() == sb`.

`virtual ~basic_ostream();`

2 *Effects:* Destroys an object of class `basic_ostream`.

3 *Remarks:* Does not perform any operations on `rdbuf()`.

`basic_ostream(basic_ostream&& rhs);`

4 *Effects:* Move constructs from the rvalue `rhs`. This is accomplished by default constructing the base class and calling `basic_ios<charT, traits>::move(rhs)` to initialize the base class.

27.190.0.1 Class `basic_ostream` assign and swap [ostream.assign]

`basic_ostream& operator=(basic_ostream&& rhs);`

1 *Effects:* `swap(rhs)`.

2 *Returns:* `*this`.

`void swap(basic_ostream& rhs);`

3 *Effects:* Calls `basic_ios<charT, traits>::swap(rhs)`.

27.190.0.2 Class `basic_ostream::sentry` [ostream::sentry]

```
namespace std {
  template <class charT,class traits = char_traits<charT> >
  class basic_ostream<charT,traits>::sentry {
    bool ok_; // exposition only
  public:
    explicit sentry(basic_ostream<charT,traits>& os);
    ~sentry();
    explicit operator bool() const { return ok_; }

    sentry(const sentry&) = delete;
    sentry& operator=(const sentry&) = delete;
  };
}
```

1 The class `sentry` defines a class that is responsible for doing exception safe prefix and suffix operations.

`explicit sentry(basic_ostream<charT,traits>& os);`

2

If `os.good()` is nonzero, prepares for formatted or unformatted output. If `os.tie()` is not a null pointer, calls `os.tie()->flush()`.[324]

1

If, after any preparation is completed, `os.good()` is `true`, `ok_ == true` otherwise, `ok_ == false`. During preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure` (27.84.0.1))[325]

`~sentry();`

324) The call `os.tie()->flush()` does not necessarily occur if the function can determine that no synchronization is necessary.
325) The `sentry` constructor and destructor can also perform additional implementation-dependent operations.

1 If `((os.flags() & ios_base::unitbuf) && !uncaught_exception() && os.good())` is `true`, calls `os.rdbuf()->pubsync()`. If that function returns -1, sets `badbit` in `os.rdstate()` without propagating an exception.

```
explicit operator bool() const;
```

2 *Effects:* Returns `ok_`.

27.196.0.1 `basic_ostream` seek members [ostream.seeks]

1 Each seek member function begins execution by constructing an object of class `sentry`. It returns by destroying the `sentry` object.

```
pos_type tellp();
```

2 *Returns:* If `fail() != false`, returns `pos_type(-1)` to indicate failure. Otherwise, returns `rdbuf()->pubseekoff(0, cur, out)`.

```
basic_ostream<charT,traits>& seekp(pos_type pos);
```

3 *Effects:* If `fail() != true`, executes `rdbuf()->pubseekpos(pos, ios_base::out)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

1 *Returns:* `*this`.

```
basic_ostream<charT,traits>& seekp(off_type off, ios_base::seekdir dir);
```

2 *Effects:* If `fail() != true`, executes `rdbuf()->pubseekoff(off, dir, ios_base::out)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

3 *Returns:* `*this`.

27.198.0.1 Formatted output functions [ostream.formatted]

27.198.0.1.1 Common requirements [ostream.formatted.reqmts]

1

Each formatted output function begins execution by constructing an object of class `sentry`. If this object returns `true` when converted to a value of type `bool`, the function endeavors to generate the requested output. If the generation fails, then the formatted output function does `setstate(ios_base::failbit)`, which might throw an exception. If an exception is thrown during output, then `ios::badbit` is turned on[326] in `*this`'s error state. If `(exceptions()&badbit) != 0` then the exception is rethrown. Whether or not an exception is thrown, the `sentry` object is destroyed before leaving the formatted output function. If no exception is thrown, the result of the formatted output function is `*this`.

1 The descriptions of the individual formatted output functions describe how they perform output and do not mention the `sentry` object.

2

If a formatted output function of a stream `os` determines padding, it does so as follows. Given a `charT` character sequence `seq` where `charT` is the character type of the stream, if the length of `seq` is less than `os.width()`, then enough copies of `os.fill()` are added to this sequence as necessary to pad to a width of `os.width()` characters. If `(os.flags() & ios_base::adjustfield) == ios_base::left` is `true`, the fill characters are placed after the character sequence; otherwise, they are placed before the character sequence.

326) without causing an `ios::failure` to be thrown.

27.203.0.0.1 Arithmetic inserters [ostream.inserters.arithmetic]

```
operator<<(bool val);
operator<<(short val);
operator<<(unsigned short val);
operator<<(int val);
operator<<(unsigned int val);
operator<<(long val);
operator<<(unsigned long val);
operator<<(long long val);
operator<<(unsigned long long val);
operator<<(float val);
operator<<(double val);
operator<<(long double val);
operator<<(const void* val);
```

1

Effects: The classes `num_get<>` and `num_put<>` handle locale-dependent numeric formatting and parsing. These inserter functions use the imbued `locale` value to perform numeric formatting. When `val` is of type `bool`, `long`, `unsigned long`, `long long`, `unsigned long long`, `double`, `long double`, or `const void*`, the formatting conversion occurs as if it performed the following code fragment:

```
bool failed = use_facet<
  num_put<charT,ostreambuf_iterator<charT,traits> >
    >(getloc()).put(*this, *this, fill(), val).failed();
```

When `val` is of type `short` the formatting conversion occurs as if it performed the following code fragment:

```
ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
bool failed = use_facet<
  num_put<charT,ostreambuf_iterator<charT,traits> >
    >(getloc()).put(*this, *this, fill(),
    baseflags == ios_base::oct || baseflags == ios_base::hex
      ? static_cast<long>(static_cast<unsigned short>(val))
      : static_cast<long>(val)).failed();
```

When `val` is of type `int` the formatting conversion occurs as if it performed the following code fragment:

```
ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
bool failed = use_facet<
  num_put<charT,ostreambuf_iterator<charT,traits> >
    >(getloc()).put(*this, *this, fill(),
    baseflags == ios_base::oct || baseflags == ios_base::hex
      ? static_cast<long>(static_cast<unsigned int>(val))
      : static_cast<long>(val)).failed();
```

When `val` is of type `unsigned short` or `unsigned int` the formatting conversion occurs as if it performed the following code fragment:

```
bool failed = use_facet<
  num_put<charT,ostreambuf_iterator<charT,traits> >
    >(getloc()).put(*this, *this, fill(),
      static_cast<unsigned long>(val)).failed();
```

When `val` is of type `float` the formatting conversion occurs as if it performed the following code fragment:

```
bool failed = use_facet<
  num_put<charT,ostreambuf_iterator<charT,traits> >
    >(getloc()).put(*this, *this, fill(),
      static_cast<double>(val)).failed();
```

1 The first argument provides an object of the `ostreambuf_iterator<>` class which is an iterator for class `basic_ostream<>`. It bypasses `ostream`s and uses `streambuf`s directly. Class `locale` relies on these types as its interface to iostreams, since for flexibility it has been abstracted away from direct dependence on `ostream`. The second parameter is a reference to the base subobject of type `ios_base`. It provides formatting specifications such as field width, and a locale from which to obtain other facets. If `failed` is `true` then does `setstate(badbit)`, which may throw an exception, and returns.

2 *Returns:* `*this`.

27.210.0.0.1 `basic_ostream::operator<<` [ostream.inserters]

```
basic_ostream<charT,traits>& operator<<
    (basic_ostream<charT,traits>& (*pf)(basic_ostream<charT,traits>&));
```

1

Effects: None. Does not behave as a formatted output function (as described in 27.198.0.1.1).

1 *Returns:* `pf(*this)`.[327]

```
basic_ostream<charT,traits>& operator<<
    (basic_ios<charT,traits>& (*pf)(basic_ios<charT,traits>&));
```

2 *Effects:* Calls `pf(*this)`. This inserter does not behave as a formatted output function (as described in 27.198.0.1.1).

3 *Returns:* `*this`.[328]

```
basic_ostream<charT,traits>& operator<<
    (ios_base& (*pf)(ios_base&));
```

4 *Effects:* Calls `pf(*this)`. This inserter does not behave as a formatted output function (as described in 27.198.0.1.1).

5 *Returns:* `*this`.

```
basic_ostream<charT,traits>& operator<<
    (basic_streambuf<charT,traits>* sb);
```

6

Effects: Behaves as an unformatted output function (as described in 27.225.0.1, paragraph 1). After the sentry object is constructed, if `sb` is null calls `setstate(badbit)` (which may throw `ios_base::failure`).

1

Gets characters from `sb` and inserts them in `*this`. Characters are read from `sb` and inserted until any of the following occurs:

— end-of-file occurs on the input sequence;

— inserting in the output sequence fails (in which case the character to be inserted is not extracted);

— an exception occurs while getting a character from `sb`.

327) See, for example, the function signature `endl(basic_ostream&)` (27.234.0.1).
328) See, for example, the function signature `dec(ios_base&)` (27.91.1.3).

1

If the function inserts no characters, it calls `setstate(failbit)` (which may throw `ios_base::failure` (27.84.0.1)). If an exception was thrown while extracting a character, the function sets `failbit` in error state, and if `failbit` is on in `exceptions()` the caught exception is rethrown.

1 *Returns:* `*this`.

27.217.0.0.1 Character inserter function templates [ostream.inserters.character]

```
template<class charT, class traits>
  basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>& out,
                                          charT c);
template<class charT, class traits>
  basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>& out,
                                          char c);
  // specialization
template<class traits>
  basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>& out,
                                         char c);
  // signed and unsigned
template<class traits>
  basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>& out,
                                         signed char c);
template<class traits>
  basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>& out,
                                         unsigned char c);
```

1

Effects: Behaves as a formatted output function (27.198.0.1.1) of `out`. Constructs a character sequence `seq`. If `c` has type `char` and the character type of the stream is not `char`, then `seq` consists of `out.widen(c)`; otherwise `seq` consists of `c`. Determines padding for `seq` as described in 27.198.0.1.1. Inserts `seq` into `out`. Calls `os.width(0)`.

1

Returns: `out`.

```
template<class charT, class traits>
  basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>& out,
                                          const charT* s);
template<class charT, class traits>
  basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>& out,
                                          const char* s);
template<class traits>
  basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>& out,
                                         const char* s);
template<class traits>
  basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>& out,
                                         const signed char* s);
template<class traits>
  basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>& out,
                                         const unsigned char* s);
```

1 *Requires:* `s` shall not be a null pointer.

2

Effects: Behaves like a formatted inserter (as described in 27.198.0.1.1) of `out`. Creates a character sequence `seq` of `n` characters starting at `s`, each widened using `out.widen()` (27.83.0.1), where `n` is the number that would be computed as if by:

— `traits::length(s)` for the overload where the first argument is of type `basic_ostream<charT, traits>&` and the second is of type `const charT*`, and also for the overload where the first argument is of type `basic_ostream<char, traits>&` and the second is of type `const char*`,

— `std::char_traits<char>::length(s)` for the overload where the first argument is of type `basic_ostream<charT, traits>&` and the second is of type `const char*`,

— `traits::length(reinterpret_cast<const char*>(s))` for the other two overloads.

Determines padding for `seq` as described in 27.198.0.1.1. Inserts `seq` into `out`. Calls `width(0)`.

1 *Returns:* `out`.

27.225.0.1 Unformatted output functions [ostream.unformatted]

1

Each unformatted output function begins execution by constructing an object of class `sentry`. If this object returns `true`, while converting to a value of type `bool`, the function endeavors to generate the requested output. If an exception is thrown during output, then `ios::badbit` is turned on[329] in `*this`'s error state. If `(exceptions() & badbit) != 0` then the exception is rethrown. In any case, the unformatted output function ends by destroying the sentry object, then, if no exception was thrown, returning the value specified for the unformatted output function.

```
basic_ostream<charT,traits>& put(char_type c);
```

1 *Effects:* Behaves as an unformatted output function (as described in 27.225.0.1, paragraph 1). After constructing a sentry object, inserts the character `c`, if possible.[330]

2 Otherwise, calls `setstate(badbit)` (which may throw `ios_base::failure` (27.84.0.1)).

3

Returns: `*this`.

```
basic_ostream& write(const char_type* s, streamsize n);
```

1

Effects: Behaves as an unformatted output function (as described in 27.225.0.1, paragraph 1). After constructing a sentry object, obtains characters to insert from successive locations of an array whose first element is designated by `s`.[331] Characters are inserted until either of the following occurs:

— `n` characters are inserted;

— inserting in the output sequence fails (in which case the function calls `setstate(badbit)`, which may throw `ios_base::failure` (27.84.0.1)).

1 *Returns:* `*this`.

```
basic_ostream& flush();
```

329) without causing an `ios::failure` to be thrown.
330) Note that this function is not overloaded on types `signed char` and `unsigned char`.
331) Note that this function is not overloaded on types `signed char` and `unsigned char`.

2

Effects: Behaves as an unformatted output function (as described in 27.198.0.1.1, paragraph 1). If `rdbuf()` is not a null pointer, constructs a sentry object. If this object returns `true` when converted to a value of type `bool` the function calls `rdbuf()->pubsync()`. If that function returns -1 calls `setstate(badbit)` (which may throw `ios_base::failure` (27.84.0.1)). Otherwise, if the sentry object returns `false`, does nothing.

1 *Returns:* `*this`.

27.234.0.1 Standard `basic_ostream` manipulators [ostream.manip]

```
namespace std {
  template <class charT, class traits>
    basic_ostream<charT,traits>& endl(basic_ostream<charT,traits>& os);
}
```

1 *Effects:* Calls `os.put(os.widen('\n'))`, then `os.flush()`.

2 *Returns:* `os`.

```
namespace std {
  template <class charT, class traits>
    basic_ostream<charT,traits>& ends(basic_ostream<charT,traits>& os);
}
```

3

Effects: Inserts a null character into the output sequence: calls `os.put(charT())`.

1 *Returns:* `os`.

```
namespace std {
  template <class charT, class traits>
    basic_ostream<charT,traits>& flush(basic_ostream<charT,traits>& os);
}
```

2 *Effects:* Calls `os.flush()`.

3 *Returns:* `os`.

27.236.0.1 Rvalue stream insertion [ostream.rvalue]

```
template <class charT, class traits, class T>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>&& os, const T& x);
```

1 *Effects:* `os << x`

2 *Returns:* `os`

27.236.1 Standard manipulators [std.manip]

1 The header `<iomanip>` defines several functions that support extractors and inserters that alter information maintained by class `ios_base` and its derived classes.

```
unspecified  resetiosflags(ios_base::fmtflags mask);
```

2 *Returns:* An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << resetiosflags(mask)` behaves as if it called `f(out, mask)`, or if

in is an object of type basic_istream<charT, traits> then the expression in >> resetiosflags(mask) behaves as if it called f(in, mask), where the function f is defined as:[332]

```
void f(ios_base& str, ios_base::fmtflags mask) {
  // reset specified flags
  str.setf(ios_base::fmtflags(0), mask);
}
```

The expression out << resetiosflags(mask) shall have type basic_ostream<charT,traits>& and value out. The expression in >> resetiosflags(mask) shall have type basic_istream<charT, traits>& and value in.

unspecified setiosflags(ios_base::fmtflags mask);

3 *Returns:* An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> then the expression out << setiosflags(mask) behaves as if it called f(out, mask), or if in is an object of type basic_istream<charT, traits> then the expression in >> setiosflags(mask) behaves as if it called f(in, mask), where the function f is defined as:

```
void f(ios_base& str, ios_base::fmtflags mask) {
  // set specified flags
  str.setf(mask);
}
```

The expression out << setiosflags(mask) shall have type basic_ostream<charT, traits>& and value out. The expression in >> setiosflags(mask) shall have type basic_istream<charT, traits>& and value in.

unspecified setbase(int base);

4 *Returns:* An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> then the expression out << setbase(base) behaves as if it called f(out, base), or if in is an object of type basic_istream<charT, traits> then the expression in >> setbase(base) behaves as if it called f(in, base), where the function f is defined as:

```
void f(ios_base& str, int base) {
  // set basefield
  str.setf(base ==  8 ? ios_base::oct :
      base == 10 ? ios_base::dec :
      base == 16 ? ios_base::hex :
      ios_base::fmtflags(0), ios_base::basefield);
}
```

The expression out << setbase(base) shall have type basic_ostream<charT, traits>& and value out. The expression in >> setbase(base) shall have type basic_istream<charT, traits>& and value in.

unspecified setfill(char_type c);

5

Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> and c has type charT then the expression out << setfill(c) behaves as if it called f(out, c), where the function f is defined as:

332) The expression cin >>resetiosflags(ios_base::skipws) clears ios_base::skipws in the format flags stored in the basic_istream<charT,traits> object cin (the same as cin >>noskipws), and the expression cout <<resetiosflags(ios_base::showbase) clears ios_base::showbase in the format flags stored in the basic_ostream<charT,traits> object cout (the same as cout <<noshowbase).

```
template<class charT, class traits>
void f(basic_ios<charT,traits>& str, charT c) {
  // set fill character
  str.fill(c);
}
```

The expression `out << setfill(c)` shall have type `basic_ostream<charT, traits>&` and value `out`.

unspecified `setprecision(int n);`

1 *Returns:* An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << setprecision(n)` behaves as if it called `f(out, n)`, or if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> setprecision(n)` behaves as if it called `f(in, n)`, where the function `f` is defined as:

```
void f(ios_base& str, int n) {
  // set precision
  str.precision(n);
}
```

The expression `out << setprecision(n)` shall have type `basic_ostream<charT, traits>&` and value `out`. The expression `in >> setprecision(n)` shall have type `basic_istream<charT, traits>&` and value `in`.

unspecified `setw(int n);`

2

Returns: An object of unspecified type such that if `out` is an instance of `basic_ostream<charT, traits>` then the expression `out << setw(n)` behaves as if it called `f(out, n)`, or if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> setw(n)` behaves as if it called `f(in, n)`, where the function `f` is defined as:

```
void f(ios_base& str, int n) {
  // set width
  str.width(n);
}
```

The expression `out << setw(n)` shall have type `basic_ostream<charT, traits>&` and value `out`. The expression `in >> setw(n)` shall have type `basic_istream<charT, traits>&` and value `in`.

27.242.1 Extended manipulators [ext.manip]

1 The header `<iomanip>` defines several functions that support extractors and inserters that allow for the parsing and formatting of sequences and values for money and time.

`template <class moneyT>` *unspecified* `get_money(moneyT& mon, bool intl = false);`

2 *Requires:* The type `moneyT` shall be either `long double` or a specialization of the `basic_string` template (Clause 21).

3 *Effects:* The expression `in >>get_money(mon, intl)` described below behaves as a formatted input function (27.128.0.1.1).

4 *Returns:* An object of unspecified type such that if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> get_money(mon, intl)` behaves as if it called `f(in, mon, intl)`, where the function `f` is defined as:

```
template <class charT, class traits, class moneyT>
void f(basic_ios<charT, traits>& str, moneyT& mon, bool intl) {
  typedef istreambuf_iterator<charT, traits> Iter;
  typedef money_get<charT, Iter> MoneyGet;

  ios_base::iostate err = ios_base::goodbit;
  const MoneyGet &mg = use_facet<MoneyGet>(str.getloc());

  mg.get(Iter(str.rdbuf()), Iter(), intl, str, err, mon);

  if (ios_base::goodbit != err)
    str.setstate(err);
}
```

The expression `in >> get_money(mon, intl)` shall have type `basic_istream<charT, traits>&` and value `in`.

`template <class moneyT> unspecified put_money(const moneyT& mon, bool intl = false);`

5 *Requires:* The type `moneyT` shall be either `long double` or a specialization of the `basic_string` template (Clause 21).

6 *Returns:* An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << put_money(mon, intl)` behaves as a formatted input function that calls `f(out, mon, intl)`, where the function `f` is defined as:

```
template <class charT, class traits, class moneyT>
void f(basic_ios<charT, traits>& str, const moneyT& mon, bool intl) {
  typedef ostreambuf_iterator<charT, traits> Iter;
  typedef money_put<charT, Iter> MoneyPut;

  const MoneyPut& mp = use_facet<MoneyPut>(str.getloc());
  const Iter end = mp.put(Iter(str.rdbuf()), intl, str, str.fill(), mon);

  if (end.failed())
    str.setstate(ios::badbit);
}
```

The expression `out << put_money(mon, intl)` shall have type `basic_ostream<charT, traits>&` and value `out`.

`template <class charT> unspecified get_time(struct tm* tmb, const charT* fmt);`

7 *Requires:* The argument `tmb` shall be a valid pointer to an object of type `struct tm`, and the argument `fmt` shall be a valid pointer to an array of objects of type `charT` with `char_traits<charT>::length(fmt)` elements.

8 *Returns:* An object of unspecified type such that if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> get_time(tmb, fmt)` behaves as if it called `f(in, tmb, fmt)`, where the function `f` is defined as:

```
template <class charT, class traits>
void f(basic_ios<charT, traits>& str, struct tm* tmb, const charT* fmt) {
  typedef istreambuf_iterator<charT, traits> Iter;
  typedef time_get<charT, Iter> TimeGet;

  ios_base::iostate err = ios_base::goodbit;
  const TimeGet& tg = use_facet<TimeGet>(str.getloc());
```

```
    tg.get(Iter(str.rdbuf()), Iter(), str, err, tmb,
      fmt, fmt + traits::length(fmt));

    if (err != ios_base::goodbit)
      str.setstate(err):
  }
```

The expression `in >> get_time(tmb, fmt)` shall have type `basic_istream<charT, traits>&` and value `in`.

```
template <class charT> unspecified  put_time(const struct tm* tmb, const charT* fmt);
```

9 *Requires:* The argument `tmb` shall be a valid pointer to an object of type `struct tm`, and the argument `fmt` shall be a valid pointer to an array of objects of type `charT` with `char_traits<charT>::length(fmt)` elements.

10 *Returns:* An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << put_time(tmb, fmt)` behaves as if it called `f(out, tmb, fmt)`, where the function `f` is defined as:

```
template <class charT, class traits>
void f(basic_ios<charT, traits>& str, const struct tm* tmb, const charT* fmt) {
  typedef ostreambuf_iterator<charT, traits> Iter;
  typedef time_put<charT, Iter> TimePut;

  const TimePut& tp = use_facet<TimePut>(str.getloc());
  const Iter end = tp.put(Iter(str.rdbuf()), str, str.fill(), tmb,
    fmt, fmt + traits::length(fmt));

  if (end.failed())
    str.setstate(ios_base::badbit);
}
```

The expression `out << put_time(tmb, fmt)` shall have type `basic_ostream<charT, traits>&` and value `out`.

27.242.2 Quoted manipulators [quoted.manip]

1 [*Note:* Quoted manipulators provide string insertion and extraction of quoted strings (for example, XML and CSV formats). Quoted manipulators are useful in ensuring that the content of a string with embedded spaces remains unchanged if inserted and then extracted via stream I/O. — *end note*]

```
template <class charT>
  unspecified  quoted(const charT* s, charT delim=charT('"'), charT escape=charT('\\'));
template <class charT, class traits, class Allocator>
  unspecified  quoted(const basic_string<charT, traits, Allocator>& s,
                      charT delim=charT('"'), charT escape=charT('\\'));
```

2 *Returns:* An object of unspecified type such that if `out` is an instance of `basic_ostream` with member type `char_type` the same as `charT` and with member type `traits_type`, which in the second form is the same as `traits`, then the expression `out << quoted(s, delim, escape)` behaves as a formatted output function (27.198.0.1.1) of `out`. This forms a character sequence `seq`, initially consisting of the following elements:

(2.1) — `delim`.

(2.2) — Each character in `s`. If the character to be output is equal to `escape` or `delim`, as determined by `traits_type::eq`, first output `escape`.

(2.3) — `delim`.

Let `x` be the number of elements initially in `seq`. Then padding is determined for `seq` as described in 27.198.0.1.1, `seq` is inserted as if by calling `out.rdbuf()->sputn(seq, n)`, where `n` is the larger of `out.width()` and `x`, and `out.width(0)` is called. The expression `out << quoted(s, delim, escape)` shall have type `basic_ostream<charT, traits>&` and value `out`.

```
template <class charT, class traits, class Allocator>
  unspecified  quoted(basic_string<charT, traits, Allocator>& s,
                      charT delim=charT('"'), charT escape=charT('\\'));
```

3 *Returns:* An object of unspecified type such that:

(3.1) — If `in` is an instance of `basic_istream` with member types `char_type` and `traits_type` the same as `charT` and `traits`, respectively, then the expression `in >> quoted(s, delim, escape)` behaves as if it extracts the following characters from `in` using `basic_istream::operator>>` (27.141.0.0.1) which may throw `ios_base::failure` (27.59.0.1.1):

(3.1.1) — If the first character extracted is equal to `delim`, as determined by `traits_type::eq`, then:

(3.1.1.1) — Turn off the `skipws` flag.

(3.1.1.2) — `s.clear()`

(3.1.1.3) — Until an unescaped `delim` character is reached or `!in`, extract characters from `in` and append them to `s`, except that if an `escape` is reached, ignore it and append the next character to `s`.

(3.1.1.4) — Discard the final `delim` character.

(3.1.1.5) — Restore the `skipws` flag to its original value.

(3.1.2) — Otherwise, `in >> s`.

(3.2) — If `out` is an instance of `basic_ostream` with member types `char_type` and `traits_type` the same as `charT` and `traits`, respectively, then the expression `out << quoted(s, delim, escape)` behaves as specified for the `const basic_string<charT, traits, Allocator>&` overload of the `quoted` function.

The expression `in >> quoted(s, delim, escape)` shall have type `basic_istream<charT, traits>&` and value `in`. The expression `out << quoted(s, delim, escape)` shall have type `basic_ostream <charT, traits>&` and value `out`.

27.243 String-based streams [string.streams]

27.243.1 Overview [string.streams.overview]

1 The header `<sstream>` defines four class templates and eight types that associate stream buffers with objects of class `basic_string`, as described in 21.26.

Header `<sstream>` synopsis

```
namespace std {
  template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT> >
    class basic_stringbuf;

  typedef basic_stringbuf<char>     stringbuf;
  typedef basic_stringbuf<wchar_t> wstringbuf;
```

```
  template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT> >
    class basic_istringstream;

  typedef basic_istringstream<char>     istringstream;
  typedef basic_istringstream<wchar_t> wistringstream;

  template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT> >
    class basic_ostringstream;
  typedef basic_ostringstream<char>     ostringstream;
  typedef basic_ostringstream<wchar_t> wostringstream;

  template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT> >
    class basic_stringstream;
  typedef basic_stringstream<char>     stringstream;
  typedef basic_stringstream<wchar_t> wstringstream;
}
```

27.243.2 Class template basic_stringbuf [stringbuf]

```
namespace std {
  template <class charT, class traits = char_traits<charT>,
      class Allocator = allocator<charT> >
  class basic_stringbuf : public basic_streambuf<charT,traits> {
  public:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;
    typedef Allocator                 allocator_type;

    // 27.243.2.1 Constructors:
    explicit basic_stringbuf(ios_base::openmode which
                             = ios_base::in | ios_base::out);
    explicit basic_stringbuf
    (const basic_string<charT,traits,Allocator>& str,
     ios_base::openmode which = ios_base::in | ios_base::out);
    basic_stringbuf(const basic_stringbuf& rhs) = delete;
    basic_stringbuf(basic_stringbuf&& rhs);

    // 27.244.0.1 Assign and swap:
    basic_stringbuf& operator=(const basic_stringbuf& rhs) = delete;
    basic_stringbuf& operator=(basic_stringbuf&& rhs);
    void swap(basic_stringbuf& rhs);

    // 27.245.0.1 Get and set:
    basic_string<charT,traits,Allocator> str() const;
    void str(const basic_string<charT,traits,Allocator>& s);

  protected:
    // 27.246.0.1 Overridden virtual functions:
    virtual int_type   underflow();
```

```
    virtual int_type   pbackfail(int_type c = traits::eof());
    virtual int_type   overflow (int_type c = traits::eof());
    virtual  basic_streambuf<charT,traits>* setbuf(charT*, streamsize);

    virtual pos_type seekoff(off_type off, ios_base::seekdir way,
                             ios_base::openmode which
                               = ios_base::in | ios_base::out);
    virtual pos_type seekpos(pos_type sp,
                             ios_base::openmode which
                               = ios_base::in | ios_base::out);

  private:
    ios_base::openmode mode;  // exposition only
  };

  template <class charT, class traits, class Allocator>
  void swap(basic_stringbuf<charT, traits, Allocator>& x,
            basic_stringbuf<charT, traits, Allocator>& y);
}
```

1 The class `basic_stringbuf` is derived from `basic_streambuf` to associate possibly the input sequence and possibly the output sequence with a sequence of arbitrary *characters*. The sequence can be initialized from, or made available as, an object of class `basic_string`.

2 For the sake of exposition, the maintained data is presented here as:

(2.1) — `ios_base::openmode mode`, has `in` set if the input sequence can be read, and `out` set if the output sequence can be written.

27.243.2.1 `basic_stringbuf` constructors [stringbuf.cons]

```
explicit basic_stringbuf(ios_base::openmode which =
                         ios_base::in | ios_base::out);
```

1 *Effects:* Constructs an object of class `basic_stringbuf`, initializing the base class with `basic_streambuf()` (27.96.0.1), and initializing `mode` with `which`.

2 *Postcondition:* `str() == ""`.

```
explicit basic_stringbuf(const basic_string<charT,traits,Allocator>& s,
                         ios_base::openmode which = ios_base::in | ios_base::out);
```

3 *Effects:* Constructs an object of class `basic_stringbuf`, initializing the base class with `basic_streambuf()` (27.96.0.1), and initializing `mode` with `which`. Then calls `str(s)`.

```
basic_stringbuf(basic_stringbuf&& rhs);
```

4

Effects: Move constructs from the rvalue `rhs`. It is implementation-defined whether the sequence pointers in `*this` (`eback()`, `gptr()`, `egptr()`, `pbase()`, `pptr()`, `epptr()`) obtain the values which `rhs` had. Whether they do or not, `*this` and `rhs` reference separate buffers (if any at all) after the construction. The openmode, locale and any other state of `rhs` is also copied.

1 *Postconditions:* Let `rhs_p` refer to the state of `rhs` just prior to this construction and let `rhs_a` refer to the state of `rhs` just after this construction.

(1.1) — `str() == rhs_p.str()`

(1.2) — `gptr() - eback() == rhs_p.gptr() - rhs_p.eback()`

(1.3) — `egptr() - eback() == rhs_p.egptr() - rhs_p.eback()`
(1.4) — `pptr() - pbase() == rhs_p.pptr() - rhs_p.pbase()`
(1.5) — `epptr() - pbase() == rhs_p.epptr() - rhs_p.pbase()`
(1.6) — `if (eback()) eback() != rhs_a.eback()`
(1.7) — `if (gptr()) gptr() != rhs_a.gptr()`
(1.8) — `if (egptr()) egptr() != rhs_a.egptr()`
(1.9) — `if (pbase()) pbase() != rhs_a.pbase()`
(1.10) — `if (pptr()) pptr() != rhs_a.pptr()`
(1.11) — `if (epptr()) epptr() != rhs_a.epptr()`

27.244.0.1 Assign and swap [stringbuf.assign]

```
basic_stringbuf& operator=(basic_stringbuf&& rhs);
```

1 *Effects:* After the move assignment `*this` has the observable state it would have had if it had been move constructed from `rhs` (see 27.243.2.1).

2 *Returns:* `*this`.

```
void swap(basic_stringbuf& rhs);
```

3 *Effects:* Exchanges the state of `*this` and `rhs`.

```
template <class charT, class traits, class Allocator>
void swap(basic_stringbuf<charT, traits, Allocator>& x,
          basic_stringbuf<charT, traits, Allocator>& y);
```

1 *Effects:* `x.swap(y)`.

27.245.0.1 Member functions [stringbuf.members]

```
basic_string<charT,traits,Allocator> str() const;
```

1 *Returns:* A `basic_string` object whose content is equal to the `basic_stringbuf` underlying character sequence. If the `basic_stringbuf` was created only in input mode, the resultant `basic_string` contains the character sequence in the range `[eback(),egptr())`. If the `basic_stringbuf` was created with `which & ios_base::out` being true then the resultant `basic_string` contains the character sequence in the range `[pbase(),high_mark)`, where `high_mark` represents the position one past the highest initialized character in the buffer. Characters can be initialized by writing to the stream, by constructing the `basic_stringbuf` with a `basic_string`, or by calling the `str(basic_string)` member function. In the case of calling the `str(basic_string)` member function, all characters initialized prior to the call are now considered uninitialized (except for those characters re-initialized by the new `basic_string`). Otherwise the `basic_stringbuf` has been created in neither input nor output mode and a zero length `basic_string` is returned.

```
void str(const basic_string<charT,traits,Allocator>& s);
```

1 *Effects:* Copies the content of `s` into the `basic_stringbuf` underlying character sequence and initializes the input and output sequences according to `mode`.

2 *Postconditions:* If `mode & ios_base::out` is true, `pbase()` points to the first underlying character and `epptr() >= pbase() + s.size()` holds; in addition, if `mode & ios_base::ate` is true, `pptr() == pbase() + s.size()` holds, otherwise `pptr() == pbase()` is true. If `mode & ios_base::in` is true, `eback()` points to the first underlying character, and both `gptr() == eback()` and `egptr() == eback() + s.size()` hold.

27.246.0.1 Overridden virtual functions [stringbuf.virtuals]

`int_type underflow();`

1 *Returns:* If the input sequence has a read position available, returns `traits::to_int_type(*gptr())`. Otherwise, returns `traits::eof()`. Any character in the underlying buffer which has been initialized is considered to be part of the input sequence.

`int_type pbackfail(int_type c = traits::eof());`

1 *Effects:* Puts back the character designated by `c` to the input sequence, if possible, in one of three ways:

(1.1) — If `traits::eq_int_type(c,traits::eof())` returns `false` and if the input sequence has a putback position available, and if `traits::eq(to_char_type(c),gptr()[-1])` returns `true`, assigns `gptr() - 1` to `gptr()`.
Returns: `c`.

(1.2) — If `traits::eq_int_type(c,traits::eof())` returns `false` and if the input sequence has a putback position available, and if `mode & ios_base::out` is nonzero, assigns `c` to `*--gptr()`.
Returns: `c`.

(1.3) — If `traits::eq_int_type(c,traits::eof())` returns `true` and if the input sequence has a putback position available, assigns `gptr() - 1` to `gptr()`.
Returns: `traits::not_eof(c)`.

2 *Returns:* `traits::eof()` to indicate failure.

3 *Remarks:* If the function can succeed in more than one of these ways, it is unspecified which way is chosen.

`int_type overflow(int_type c = traits::eof());`

4 *Effects:* Appends the character designated by `c` to the output sequence, if possible, in one of two ways:

(4.1) — If `traits::eq_int_type(c,traits::eof())` returns `false` and if either the output sequence has a write position available or the function makes a write position available (as described below), the function calls `sputc(c )`.
Signals success by returning `c`.

(4.2) — If `traits::eq_int_type(c,traits::eof())` returns `true`, there is no character to append.
Signals success by returning a value other than `traits::eof()`.

5 *Remarks:* The function can alter the number of write positions available as a result of any call.

6 *Returns:* `traits::eof()` to indicate failure.

7 The function can make a write position available only if `(mode & ios_base::out) != 0`. To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements to hold the current array object (if any), plus at least one additional write position. If `(mode & ios_base::in) != 0`, the function alters the read end pointer `egptr()` to point just past the new write position.

```
pos_type seekoff(off_type off, ios_base::seekdir way,
                 ios_base::openmode which
                   = ios_base::in | ios_base::out);
```

Table 130 — `seekoff` positioning

Conditions	Result
`(which & ios_base::in) == ios_base::in`	positions the input sequence
`(which & ios_base::out) == ios_base::out`	positions the output sequence
`(which & (ios_base::in | ios_base::out)) == (ios_base::in) | ios_base::out))` and `way ==` either `ios_base::beg` or `ios_base::end`	positions both the input and the output sequences
Otherwise	the positioning operation fails.

8 *Effects:* Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 130.

9 For a sequence to be positioned, if its next pointer (either `gptr()` or `pptr()`) is a null pointer and the new offset `newoff` is nonzero, the positioning operation fails. Otherwise, the function determines `newoff` as indicated in Table 131.

Table 131 — `newoff` values

Condition	`newoff` Value
`way == ios_base::beg`	0
`way == ios_base::cur`	the next pointer minus the beginning pointer (`xnext - xbeg`).
`way == ios_base::end`	the high mark pointer minus the beginning pointer (`high_mark - xbeg`).

10 If `(newoff + off) < 0`, or if `newoff + off` refers to an uninitialized character (as defined in 27.245.0.1 paragraph 1), the positioning operation fails. Otherwise, the function assigns `xbeg + newoff + off` to the next pointer `xnext`.

11 *Returns:* `pos_type(newoff)`, constructed from the resultant offset `newoff` (of type `off_type`), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is `pos_type(off_type(-1))`.

```
pos_type seekpos(pos_type sp, ios_base::openmode which
                 = ios_base::in | ios_base::out);
```

12 *Effects:* Equivalent to `seekoff(off_type(sp), ios_base::beg, which)`.

13 *Returns:* `sp` to indicate success, or `pos_type(off_type(-1))` to indicate failure.

```
basic_streambuf<charT,traits>* setbuf(charT* s, streamsize n);
```

14 *Effects:* implementation-defined, except that `setbuf(0,0)` has no effect.

15 *Returns:* `this`.

27.247.1 Class template basic_istringstream [istringstream]

```
namespace std {
  template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT> >
  class basic_istringstream : public basic_istream<charT,traits> {
  public:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;
    typedef Allocator                 allocator_type;

    // 27.247.1.1 Constructors:
    explicit basic_istringstream(ios_base::openmode which = ios_base::in);
    explicit basic_istringstream(
               const basic_string<charT,traits,Allocator>& str,
               ios_base::openmode which = ios_base::in);
    basic_istringstream(const basic_istringstream& rhs) = delete;
    basic_istringstream(basic_istringstream&& rhs);

    // 27.247.1.2 Assign and swap:
    basic_istringstream& operator=(const basic_istringstream& rhs) = delete;
    basic_istringstream& operator=(basic_istringstream&& rhs);
    void swap(basic_istringstream& rhs);

    // 27.247.1.3 Members:
    basic_stringbuf<charT,traits,Allocator>* rdbuf() const;

    basic_string<charT,traits,Allocator> str() const;
    void str(const basic_string<charT,traits,Allocator>& s);
  private:
    basic_stringbuf<charT,traits,Allocator> sb; // exposition only
  };

  template <class charT, class traits, class Allocator>
  void swap(basic_istringstream<charT, traits, Allocator>& x,
            basic_istringstream<charT, traits, Allocator>& y);
}
```

1 The class basic_istringstream<charT, traits, Allocator> supports reading objects of class basic_string<charT, traits, Allocator>. It uses a basic_stringbuf<charT, traits, Allocator> object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

(1.1) — sb, the stringbuf object.

27.247.1.1 basic_istringstream constructors [istringstream.cons]

```
explicit basic_istringstream(ios_base::openmode which = ios_base::in);
```

1 *Effects:* Constructs an object of class basic_istringstream<charT, traits>, initializing the base class with basic_istream(&sb) and initializing sb with basic_stringbuf<charT, traits, Allocator>(which | ios_base::in)) (27.243.2.1).

```
explicit basic_istringstream(
               const basic_string<charT, traits, Allocator>& str,
```

```
                ios_base::openmode which = ios_base::in);
```

2 *Effects:* Constructs an object of class `basic_istringstream<charT, traits>`, initializing the base class with `basic_istream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(str, which | ios_base::in))` (27.243.2.1).

```
basic_istringstream(basic_istringstream&& rhs);
```

3 *Effects:* Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Next `basic_istream<charT,traits>::set_rdbuf(&sb)` is called to install the contained `basic_stringbuf`.

27.247.1.2 Assign and swap [istringstream.assign]

```
basic_istringstream& operator=(basic_istringstream&& rhs);
```

1 *Effects:* Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

2 *Returns:* `*this`.

```
void swap(basic_istringstream& rhs);
```

3 *Effects:* Exchanges the state of `*this` and `rhs` by calling `basic_istream<charT,traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template <class charT, class traits, class Allocator>
void swap(basic_istringstream<charT, traits, Allocator>& x,
          basic_istringstream<charT, traits, Allocator>& y);
```

4 *Effects:* `x.swap(y)`.

27.247.1.3 Member functions [istringstream.members]

```
basic_stringbuf<charT,traits,Allocator>* rdbuf() const;
```

1 *Returns:* `const_cast<basic_stringbuf<charT,traits,Allocator>*>(&sb)`.

```
basic_string<charT,traits,Allocator> str() const;
```

2 *Returns:* `rdbuf()->str()`.

```
void str(const basic_string<charT,traits,Allocator>& s);
```

3 *Effects:* Calls `rdbuf()->str(s)`.

27.247.2 Class template basic_ostringstream [ostringstream]

```
namespace std {
  template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT> >
  class basic_ostringstream : public basic_ostream<charT,traits> {
  public:

    // types:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;
    typedef Allocator                 allocator_type;
```

```
    // 27.247.2.1 Constructors/destructor:
    explicit basic_ostringstream(ios_base::openmode which = ios_base::out);
    explicit basic_ostringstream(
             const basic_string<charT,traits,Allocator>& str,
             ios_base::openmode which = ios_base::out);
    basic_ostringstream(const basic_ostringstream& rhs) = delete;
    basic_ostringstream(basic_ostringstream&& rhs);

    // 27.247.2.2 Assign/swap:
    basic_ostringstream& operator=(const basic_ostringstream& rhs) = delete;
    basic_ostringstream& operator=(basic_ostringstream&& rhs);
    void swap(basic_ostringstream& rhs);

    // 27.247.2.3 Members:
    basic_stringbuf<charT,traits,Allocator>* rdbuf() const;

    basic_string<charT,traits,Allocator> str() const;
    void    str(const basic_string<charT,traits,Allocator>& s);
   private:
    basic_stringbuf<charT,traits,Allocator> sb; // exposition only
  };

  template <class charT, class traits, class Allocator>
  void swap(basic_ostringstream<charT, traits, Allocator>& x,
            basic_ostringstream<charT, traits, Allocator>& y);
}
```

1 The class `basic_ostringstream<charT, traits, Allocator>` supports writing objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf` object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

(1.1) — `sb`, the `stringbuf` object.

27.247.2.1 `basic_ostringstream` constructors [ostringstream.cons]

```
explicit basic_ostringstream(ios_base::openmode which = ios_base::out);
```

1 *Effects:* Constructs an object of class `basic_ostringstream`, initializing the base class with `basic_ostream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(which | ios_base::out))` (27.243.2.1).

```
explicit basic_ostringstream(
  const basic_string<charT,traits,Allocator>& str,
  ios_base::openmode which = ios_base::out);
```

2 *Effects:* Constructs an object of class `basic_ostringstream<charT, traits>`, initializing the base class with `basic_ostream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(str, which | ios_base::out))` (27.243.2.1).

```
basic_ostringstream(basic_ostringstream&& rhs);
```

3 *Effects:* Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Next `basic_ostream<charT,traits>::set_rdbuf(&sb)` is called to install the contained `basic_stringbuf`.

27.247.2.2 Assign and swap [ostringstream.assign]

```
basic_ostringstream& operator=(basic_ostringstream&& rhs);
```

1 *Effects:* Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

2 *Returns:* `*this`.

```
void swap(basic_ostringstream& rhs);
```

3 *Effects:* Exchanges the state of `*this` and `rhs` by calling `basic_ostream<charT,traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template <class charT, class traits, class Allocator>
void swap(basic_ostringstream<charT, traits, Allocator>& x,
          basic_ostringstream<charT, traits, Allocator>& y);
```

4 *Effects:* `x.swap(y)`.

27.247.2.3 Member functions [ostringstream.members]

```
basic_stringbuf<charT,traits,Allocator>* rdbuf() const;
```

1 *Returns:* `const_cast<basic_stringbuf<charT,traits,Allocator>*>(&sb)`.

```
basic_string<charT,traits,Allocator> str() const;
```

2 *Returns:* `rdbuf()->str()`.

```
void str(const basic_string<charT,traits,Allocator>& s);
```

3 *Effects:* Calls `rdbuf()->str(s)`.

27.247.3 Class template `basic_stringstream` [stringstream]

```
namespace std {
  template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT> >
  class basic_stringstream
    : public basic_iostream<charT,traits> {
  public:

    // types:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;
    typedef Allocator                 allocator_type;

    // constructors/destructor
    explicit basic_stringstream(
    ios_base::openmode which = ios_base::out|ios_base::in);
    explicit basic_stringstream(
    const basic_string<charT,traits,Allocator>& str,
    ios_base::openmode which = ios_base::out|ios_base::in);
    basic_stringstream(const basic_stringstream& rhs) = delete;
    basic_stringstream(basic_stringstream&& rhs);
```

```
    // 27.247.3.2 Assign/swap:
    basic_stringstream& operator=(const basic_stringstream& rhs) = delete;
    basic_stringstream& operator=(basic_stringstream&& rhs);
    void swap(basic_stringstream& rhs);

    // Members:
    basic_stringbuf<charT,traits,Allocator>* rdbuf() const;
    basic_string<charT,traits,Allocator> str() const;
    void str(const basic_string<charT,traits,Allocator>& str);

  private:
    basic_stringbuf<charT, traits> sb;  // exposition only
  };

  template <class charT, class traits, class Allocator>
  void swap(basic_stringstream<charT, traits, Allocator>& x,
            basic_stringstream<charT, traits, Allocator>& y);
}
```

1 The class template `basic_stringstream<charT, traits>` supports reading and writing from objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf<charT, traits, Allocator>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as

(1.1) — `sb`, the `stringbuf` object.

27.247.3.1 basic_stringstream constructors [stringstream.cons]

```
explicit basic_stringstream(
    ios_base::openmode which = ios_base::out|ios_base::in);
```

1 *Effects:* Constructs an object of class `basic_stringstream<charT,traits>`, initializing the base class with `basic_iostream(&sb)` and initializing `sb` with `basic_stringbuf<charT,traits,Allocator>(which)`.

```
explicit basic_stringstream(
    const basic_string<charT,traits,Allocator>& str,
    ios_base::openmode which = ios_base::out|ios_base::in);
```

2 *Effects:* Constructs an object of class `basic_stringstream<charT, traits>`, initializing the base class with `basic_iostream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(str, which)`.

```
basic_stringstream(basic_stringstream&& rhs);
```

3 *Effects:* Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Next `basic_istream<charT,traits>::set_rdbuf(&sb)` is called to install the contained `basic_stringbuf`.

27.247.3.2 Assign and swap [stringstream.assign]

```
basic_stringstream& operator=(basic_stringstream&& rhs);
```

1 *Effects:* Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

2 *Returns:* `*this`.

```
void swap(basic_stringstream& rhs);
```

3 *Effects:* Exchanges the state of `*this` and `rhs` by calling `basic_iostream<charT,traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template <class charT, class traits, class Allocator>
void swap(basic_stringstream<charT, traits, Allocator>& x,
          basic_stringstream<charT, traits, Allocator>& y);
```

4 *Effects:* `x.swap(y)`.

27.247.3.3 Member functions [stringstream.members]

```
basic_stringbuf<charT,traits,Allocator>* rdbuf() const;
```

1 *Returns:* `const_cast<basic_stringbuf<charT,traits,Allocator>*>(&sb)`

```
basic_string<charT,traits,Allocator> str() const;
```

2 *Returns:* `rdbuf()->str()`.

```
void str(const basic_string<charT,traits,Allocator>& str);
```

3 *Effects:* Calls `rdbuf()->str(str)`.

27.248 File-based streams [file.streams]

27.248.1 File streams [fstreams]

1 The header `<fstream>` defines four class templates and eight types that associate stream buffers with files and assist reading and writing files.

Header `<fstream>` synopsis

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
    class basic_filebuf;
  typedef basic_filebuf<char>    filebuf;
  typedef basic_filebuf<wchar_t> wfilebuf;

  template <class charT, class traits = char_traits<charT> >
    class basic_ifstream;
  typedef basic_ifstream<char>    ifstream;
  typedef basic_ifstream<wchar_t> wifstream;

  template <class charT, class traits = char_traits<charT> >
    class basic_ofstream;
  typedef basic_ofstream<char>    ofstream;
  typedef basic_ofstream<wchar_t> wofstream;

  template <class charT, class traits = char_traits<charT> >
    class basic_fstream;
  typedef basic_fstream<char>     fstream;
  typedef basic_fstream<wchar_t> wfstream;
}
```

2 In this subclause, the type name `FILE` refers to the type `FILE` declared in `<cstdio>` (27.310.1).

3 [*Note:* The class template `basic_filebuf` treats a file as a source or sink of bytes. In an environment that uses a large character set, the file typically holds multibyte character sequences and the `basic_filebuf` object converts those multibyte sequences into wide character sequences. — *end note*]

27.248.1.1 Class template basic_filebuf [filebuf]

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
  class basic_filebuf : public basic_streambuf<charT,traits> {
  public:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;

    // 27.263.0.1 Constructors/destructor:
    basic_filebuf();
    basic_filebuf(const basic_filebuf& rhs) = delete;
    basic_filebuf(basic_filebuf&& rhs);
    virtual ~basic_filebuf();

    // 27.269.0.1 Assign/swap:
    basic_filebuf& operator=(const basic_filebuf& rhs) = delete;
    basic_filebuf& operator=(basic_filebuf&& rhs);
    void swap(basic_filebuf& rhs);

     // 27.269.0.2 Members:
    bool is_open() const;
    basic_filebuf<charT,traits>* open(const char* s,
        ios_base::openmode mode);
    basic_filebuf<charT,traits>* open(const string& s,
        ios_base::openmode mode);
    basic_filebuf<charT,traits>* close();

  protected:
    // 27.288.0.1 Overridden virtual functions:
    virtual streamsize showmanyc();
    virtual int_type underflow();
    virtual int_type uflow();
    virtual int_type pbackfail(int_type c = traits::eof());
    virtual int_type overflow (int_type c = traits::eof());

    virtual basic_streambuf<charT,traits>*
        setbuf(char_type* s, streamsize n);
    virtual pos_type seekoff(off_type off, ios_base::seekdir way,
        ios_base::openmode which = ios_base::in | ios_base::out);
    virtual pos_type seekpos(pos_type sp,
        ios_base::openmode which = ios_base::in | ios_base::out);
    virtual int      sync();
    virtual void     imbue(const locale& loc);
  };

  template <class charT, class traits>
  void swap(basic_filebuf<charT, traits>& x,
            basic_filebuf<charT, traits>& y);
}
```

1

The class basic_filebuf<charT,traits> associates both the input sequence and the output sequence with a file.

1

The restrictions on reading and writing a sequence controlled by an object of class basic_filebuf<charT, traits> are the same as for reading and writing with the Standard C library FILEs.

1

In particular:

— If the file is not open for reading the input sequence cannot be read.

— If the file is not open for writing the output sequence cannot be written.

— A joint file position is maintained for both the input sequence and the output sequence.

1 An instance of basic_filebuf behaves as described in 27.248.1.1 provided traits::pos_type is fpos<traits::state_type>. Otherwise the behavior is undefined.

2 In order to support file I/O and multibyte/wide character conversion, conversions are performed using members of a facet, referred to as a_codecvt in following sections, obtained as if by

```
const codecvt<charT,char,typename traits::state_type>& a_codecvt =
  use_facet<codecvt<charT,char,typename traits::state_type> >(getloc());
```

27.263.0.1 basic_filebuf constructors [filebuf.cons]

basic_filebuf();

1 *Effects:* Constructs an object of class basic_filebuf<charT,traits>, initializing the base class with basic_streambuf<charT,traits>() (27.96.0.1).

2 *Postcondition:* is_open() == false.

basic_filebuf(basic_filebuf&& rhs);

3 *Effects:* Move constructs from the rvalue rhs. It is implementation-defined whether the sequence pointers in *this (eback(), gptr(), egptr(), pbase(), pptr(), epptr()) obtain the values which rhs had. Whether they do or not, *this and rhs reference separate buffers (if any at all) after the construction. Additionally *this references the file which rhs did before the construction, and rhs references no file after the construction. The openmode, locale and any other state of rhs is also copied.

4 *Postconditions:* Let rhs_p refer to the state of rhs just prior to this construction and let rhs_a refer to the state of rhs just after this construction.

(4.1) — is_open() == rhs_p.is_open()

(4.2) — rhs_a.is_open() == false

(4.3) — gptr() - eback() == rhs_p.gptr() - rhs_p.eback()

(4.4) — egptr() - eback() == rhs_p.egptr() - rhs_p.eback()

(4.5) — pptr() - pbase() == rhs_p.pptr() - rhs_p.pbase()

(4.6) — epptr() - pbase() == rhs_p.epptr() - rhs_p.pbase()

(4.7) — if (eback()) eback() != rhs_a.eback()

(4.8) — if (gptr()) gptr() != rhs_a.gptr()

(4.9) — if (egptr()) egptr() != rhs_a.egptr()

(4.10) — `if (pbase()) pbase() != rhs_a.pbase()`

(4.11) — `if (pptr()) pptr() != rhs_a.pptr()`

(4.12) — `if (epptr()) epptr() != rhs_a.epptr()`

```
virtual ~basic_filebuf();
```

5

Effects: Destroys an object of class `basic_filebuf<charT,traits>`. Calls `close()`. If an exception occurs during the destruction of the object, including the call to `close()`, the exception is caught but not rethrown (see 17.677.0.1).

27.269.0.1 Assign and swap [filebuf.assign]

```
basic_filebuf& operator=(basic_filebuf&& rhs);
```

1 *Effects:* Calls `this->close()` then move assigns from `rhs`. After the move assignment `*this` has the observable state it would have had if it had been move constructed from `rhs` (see 27.263.0.1).

2 *Returns:* `*this`.

```
void swap(basic_filebuf& rhs);
```

3 *Effects:* Exchanges the state of `*this` and `rhs`.

```
template <class charT, class traits>
void swap(basic_filebuf<charT, traits>& x,
          basic_filebuf<charT, traits>& y);
```

4 *Effects:* `x.swap(y)`.

27.269.0.2 Member functions [filebuf.members]

```
bool is_open() const;
```

1

Returns: `true` if a previous call to `open` succeeded (returned a non-null value) and there has been no intervening call to close.

```
basic_filebuf<charT,traits>* open(const char* s,
    ios_base::openmode mode);
```

1

Effects: If `is_open() != false`, returns a null pointer. Otherwise, initializes the `filebuf` as required. It then opens a file, if possible, whose name is the NTBS `s` (as if by calling `std::fopen(s,modstr)`). The NTBS `modstr` is determined from `mode & ~ios_base::ate` as indicated in Table 132. If `mode` is not some combination of flags shown in the table then the open fails.

1

If the open operation succeeds and `(mode & ios_base::ate) != 0`, positions the file to the end (as if by calling `std::fseek(file,0,SEEK_END)`).[333]

1 If the repositioning operation fails, calls `close()` and returns a null pointer to indicate failure.

2

Returns: `this` if successful, a null pointer otherwise.

333) The macro `SEEK_END` is defined, and the function signatures `fopen(const char*, const char*)` and `fseek(FILE*, long, int)` are declared, in `<cstdio>` (27.310.1).

Table 132 — File open modes

ios_base flag combination					stdio equivalent
binary	in	out	trunc	app	
		+			"w"
		+		+	"a"
				+	"a"
		+	+		"w"
	+				"r"
	+	+			"r+"
	+	+	+		"w+"
	+	+		+	"a+"
	+			+	"a+"
+		+			"wb"
+		+		+	"ab"
+				+	"ab"
+		+	+		"wb"
+	+				"rb"
+	+	+			"r+b"
+	+	+	+		"w+b"
+	+	+		+	"a+b"
+	+			+	"a+b"

```
basic_filebuf<charT,traits>* open(const string& s,
    ios_base::openmode mode);
```

Returns: `open(s.c_str(), mode);`

```
basic_filebuf<charT,traits>* close();
```

1 *Effects:* If `is_open() == false`, returns a null pointer. If a put area exists, calls `overflow(traits::eof())` to flush characters. If the last virtual member function called on `*this` (between `underflow`, `overflow`, `seekoff`, and `seekpos`) was `overflow` then calls `a_codecvt.unshift` (possibly several times) to determine a termination sequence, inserts those characters and calls `overflow(traits::eof())` again. Finally, regardless of whether any of the preceding calls fails or throws an exception, the function closes the file (as if by calling `std::fclose(file)`).[334] If any of the calls made by the function, including `std::fclose`, fails, `close` fails by returning a null pointer. If one of these calls throws an exception, the exception is caught and rethrown after closing the file.

1 *Returns:* `this` on success, a null pointer otherwise.

2 *Postcondition:* `is_open() == false`.

27.288.0.1 Overridden virtual functions [filebuf.virtuals]

```
streamsize showmanyc();
```

1 *Effects:* Behaves the same as `basic_streambuf::showmanyc()` (27.99.0.2).

2 *Remarks:* An implementation might well provide an overriding definition for this function signature if it can determine that more characters can be read from the input sequence.

334) The function signature `fclose(FILE*)` is declared in `<cstdio>` (27.310.1).

`int_type underflow();`

1 *Effects:* Behaves according to the description of `basic_streambuf<charT,traits>::underflow()`, with the specialization that a sequence of characters is read from the input sequence as if by reading from the associated file into an internal buffer (`extern_buf`) and then as if by doing

```
char   extern_buf[XSIZE];
char*  extern_end;
charT  intern_buf[ISIZE];
charT* intern_end;
codecvt_base::result r =
  a_codecvt.in(state, extern_buf, extern_buf+XSIZE, extern_end,
               intern_buf, intern_buf+ISIZE, intern_end);
```

This shall be done in such a way that the class can recover the position (`fpos_t`) corresponding to each character between `intern_buf` and `intern_end`. If the value of `r` indicates that `a_codecvt.in()` ran out of space in `intern_buf`, retry with a larger `intern_buf`.

`int_type uflow();`

2

Effects: Behaves according to the description of `basic_streambuf<charT,traits>::uflow()`, with the specialization that a sequence of characters is read from the input with the same method as used by `underflow`.

`int_type pbackfail(int_type c = traits::eof());`

1 *Effects:* Puts back the character designated by `c` to the input sequence, if possible, in one of three ways:

(1.1) — If `traits::eq_int_type(c,traits::eof())` returns `false` and if the function makes a putback position available and if `traits::eq(to_char_type(c),gptr()[-1])` returns `true`, decrements the next pointer for the input sequence, `gptr()`.

Returns: `c`.

(1.2) — If `traits::eq_int_type(c,traits::eof())` returns `false` and if the function makes a putback position available and if the function is permitted to assign to the putback position, decrements the next pointer for the input sequence, and stores `c` there.

Returns: `c`.

(1.3) — If `traits::eq_int_type(c,traits::eof())` returns `true`, and if either the input sequence has a putback position available or the function makes a putback position available, decrements the next pointer for the input sequence, `gptr()`.

Returns: `traits::not_eof(c)`.

2 *Returns:* `traits::eof()` to indicate failure.

3 *Remarks:* If `is_open() == false`, the function always fails.

4 The function does not put back a character directly to the input sequence.

5 If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

`int_type overflow(int_type c = traits::eof());`

6 *Effects:* Behaves according to the description of `basic_streambuf<charT,traits>::overflow(c)`, except that the behavior of "consuming characters" is performed by first converting as if by:

```
charT* b = pbase();
charT* p = pptr();
charT* end;
char   xbuf[XSIZE];
char*  xbuf_end;
codecvt_base::result r =
  a_codecvt.out(state, b, p, end, xbuf, xbuf+XSIZE, xbuf_end);
```

and then

(6.1) — If `r == codecvt_base::error` then fail.

(6.2) — If `r == codecvt_base::noconv` then output characters from `b` up to (and not including) `p`.

(6.3) — If `r == codecvt_base::partial` then output to the file characters from `xbuf` up to `xbuf_end`, and repeat using characters from `end` to `p`. If output fails, fail (without repeating).

(6.4) — Otherwise output from `xbuf` to `xbuf_end`, and fail if output fails. At this point if `b != p` and `b == end` (`xbuf` isn't large enough) then increase `XSIZE` and repeat from the beginning.

7 *Returns:* `traits::not_eof(c)` to indicate success, and `traits::eof()` to indicate failure. If `is_open() == false`, the function always fails.

```
basic_streambuf* setbuf(char_type* s, streamsize n);
```

8

Effects: If `setbuf(0,0)` is called on a stream before any I/O has occurred on that stream, the stream becomes unbuffered. Otherwise the results are implementation-defined. "Unbuffered" means that `pbase()` and `pptr()` always return null and output to the file should appear as soon as possible.

```
pos_type seekoff(off_type off, ios_base::seekdir way,
    ios_base::openmode which = ios_base::in | ios_base::out);
```

1

Effects: Let `width` denote `a_codecvt.encoding()`. If `is_open() == false`, or `off != 0 && width <= 0`, then the positioning operation fails. Otherwise, if `way != basic_ios::cur` or `off != 0`, and if the last operation was output, then update the output sequence and write any unshift sequence. Next, seek to the new position: if `width > 0`, call `std::fseek(file, width * off, whence)`, otherwise call `std::fseek(file, 0, whence)`.

1 *Remarks:* "The last operation was output" means either the last virtual operation was overflow or the put buffer is non-empty. "Write any unshift sequence" means, if `width` if less than zero then call `a_codecvt.unshift(state, xbuf, xbuf+XSIZE, xbuf_end)` and output the resulting unshift sequence. The function determines one of three values for the argument `whence`, of type `int`, as indicated in Table 133.

Table 133 — `seekoff` effects

`way` Value	`stdio` Equivalent
`basic_ios::beg`	`SEEK_SET`
`basic_ios::cur`	`SEEK_CUR`
`basic_ios::end`	`SEEK_END`

2 *Returns:* A newly constructed `pos_type` object that stores the resultant stream position, if possible. If the positioning operation fails, or if the object cannot represent the resultant stream position, returns `pos_type(off_type(-1))`.

```
pos_type seekpos(pos_type sp,
    ios_base::openmode which = ios_base::in | ios_base::out);
```

3 Alters the file position, if possible, to correspond to the position stored in `sp` (as described below). Altering the file position performs as follows:

1. if `(om & ios_base::out) != 0`, then update the output sequence and write any unshift sequence;
2. set the file position to `sp`;
3. if `(om & ios_base::in) != 0`, then update the input sequence;

where `om` is the open mode passed to the last call to `open()`. The operation fails if `is_open()` returns false.

4 If `sp` is an invalid stream position, or if the function positions neither sequence, the positioning operation fails. If `sp` has not been obtained by a previous successful call to one of the positioning functions (`seekoff` or `seekpos`) on the same file the effects are undefined.

5 *Returns:* `sp` on success. Otherwise returns `pos_type(off_type(-1))`.

```
int sync();
```

6 *Effects:* If a put area exists, calls `filebuf::overflow` to write the characters to the file. If a get area exists, the effect is implementation-defined.

```
void imbue(const locale& loc);
```

7 *Requires:* If the file is not positioned at its beginning and the encoding of the current locale as determined by `a_codecvt.encoding()` is state-dependent (22.41.0.0.1) then that facet is the same as the corresponding facet of `loc`.

8 *Effects:* Causes characters inserted or extracted after this call to be converted according to `loc` until another call of `imbue`.

9 *Remark:* This may require reconversion of previously converted characters. This in turn may require the implementation to be able to reconstruct the original contents of the file.

27.292.0.1 Class template `basic_ifstream` [ifstream]

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
  class basic_ifstream : public basic_istream<charT,traits> {
  public:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;

    // 27.292.0.2 Constructors:
    basic_ifstream();
    explicit basic_ifstream(const char* s,
        ios_base::openmode mode = ios_base::in);
    explicit basic_ifstream(const string& s,
        ios_base::openmode mode = ios_base::in);
    basic_ifstream(const basic_ifstream& rhs) = delete;
    basic_ifstream(basic_ifstream&& rhs);

    // 27.297.0.1 Assign/swap:
```

```
    basic_ifstream& operator=(const basic_ifstream& rhs) = delete;
    basic_ifstream& operator=(basic_ifstream&& rhs);
    void swap(basic_ifstream& rhs);

    // 27.297.0.2 Members:
    basic_filebuf<charT,traits>* rdbuf() const;

    bool is_open() const;
    void open(const char* s, ios_base::openmode mode = ios_base::in);
    void open(const string& s, ios_base::openmode mode = ios_base::in);
    void close();
  private:
    basic_filebuf<charT,traits> sb; // exposition only
  };

  template <class charT, class traits>
  void swap(basic_ifstream<charT, traits>& x,
            basic_ifstream<charT, traits>& y);
}
```

1 The class `basic_ifstream<charT, traits>` supports reading from named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

(1.1) — `sb`, the `filebuf` object.

27.292.0.2 `basic_ifstream` constructors [ifstream.cons]

```
basic_ifstream();
```

1 *Effects:* Constructs an object of class `basic_ifstream<charT,traits>`, initializing the base class with `basic_istream(&sb)` and initializing `sb` with `basic_filebuf<charT,traits>()` (27.116.0.0.1, 27.263.0.1).

```
explicit basic_ifstream(const char* s,
    ios_base::openmode mode = ios_base::in);
```

1 *Effects:* Constructs an object of class `basic_ifstream`, initializing the base class with `basic_istream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()` (27.116.0.0.1, 27.263.0.1), then calls `rdbuf()->open(s, mode | ios_base::in)`. If that function returns a null pointer, calls `setstate(failbit)`.

```
explicit basic_ifstream(const string& s,
    ios_base::openmode mode = ios_base::in);
```

1 *Effects:* the same as `basic_ifstream(s.c_str(), mode)`.

```
basic_ifstream(basic_ifstream&& rhs);
```

2 *Effects:* Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_filebuf`. Next `basic_istream<charT,traits>::set_rdbuf(&sb)` is called to install the contained `basic_filebuf`.

27.297.0.1 Assign and swap [ifstream.assign]

```
basic_ifstream& operator=(basic_ifstream&& rhs);
```

1 *Effects:* Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

2 *Returns:* `*this`.

```
void swap(basic_ifstream& rhs);
```

3 *Effects:* Exchanges the state of `*this` and `rhs` by calling `basic_istream<charT,traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template <class charT, class traits>
void swap(basic_ifstream<charT, traits>& x,
          basic_ifstream<charT, traits>& y);
```

4 *Effects:* `x.swap(y)`.

27.297.0.2 Member functions [ifstream.members]

```
basic_filebuf<charT,traits>* rdbuf() const;
```

1 *Returns:* `const_cast<basic_filebuf<charT,traits>*>(&sb)`.

```
bool is_open() const;
```

2

Returns: `rdbuf()->is_open()`.

```
void open(const char* s, ios_base::openmode mode = ios_base::in);
```

1

Effects: Calls `rdbuf()->open(s, mode | ios_base::in)`. If that function does not return a null pointer calls `clear()`, otherwise calls `setstate(failbit)` (which may throw `ios_base::failure` (27.84.0.1)).

```
void open(const string& s, ios_base::openmode mode = ios_base::in);
```

1 *Effects:* calls `open(s.c_str(), mode)`.

```
void close();
```

2

Effects: Calls `rdbuf()->close()` and, if that function returns a null pointer, calls `setstate(failbit)` (which may throw `ios_base::failure` (27.84.0.1)).

27.303.0.1 Class template `basic_ofstream` [ofstream]

```
namespace std {
  template <class charT, class traits = char_traits<charT> >
  class basic_ofstream : public basic_ostream<charT,traits> {
  public:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;
```

```
    // 27.303.0.2 Constructors:
    basic_ofstream();
    explicit basic_ofstream(const char* s,
        ios_base::openmode mode = ios_base::out);
    explicit basic_ofstream(const string& s,
        ios_base::openmode mode = ios_base::out);
    basic_ofstream(const basic_ofstream& rhs) = delete;
    basic_ofstream(basic_ofstream&& rhs);

    // 27.306.0.1 Assign/swap:
    basic_ofstream& operator=(const basic_ofstream& rhs) = delete;
    basic_ofstream& operator=(basic_ofstream&& rhs);
    void swap(basic_ofstream& rhs);

    // 27.306.0.2 Members:
    basic_filebuf<charT,traits>* rdbuf() const;

    bool is_open() const;
    void open(const char* s, ios_base::openmode mode = ios_base::out);
    void open(const string& s, ios_base::openmode mode = ios_base::out);
    void close();
  private:
    basic_filebuf<charT,traits> sb; // exposition only
  };

  template <class charT, class traits>
  void swap(basic_ofstream<charT, traits>& x,
            basic_ofstream<charT, traits>& y);
}
```

1 The class `basic_ofstream<charT, traits>` supports writing to named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

(1.1) — `sb`, the `filebuf` object.

27.303.0.2 `basic_ofstream` constructors [ofstream.cons]

`basic_ofstream();`

1 *Effects:* Constructs an object of class `basic_ofstream<charT,traits>`, initializing the base class with `basic_ostream(&sb)` and initializing `sb` with `basic_filebuf<charT,traits>()` (27.188.0.1, 27.263.0.1).

```
explicit basic_ofstream(const char* s,
    ios_base::openmode mode = ios_base::out);
```

1 *Effects:* Constructs an object of class `basic_ofstream<charT,traits>`, initializing the base class with `basic_ostream(&sb)` and initializing `sb` with `basic_filebuf<charT,traits>()` (27.188.0.1, 27.263.0.1), then calls `rdbuf()->open(s, mode|ios_base::out)`. If that function returns a null pointer, calls `setstate(failbit)`.

```
explicit basic_ofstream(const string& s,
    ios_base::openmode mode = ios_base::out);
```

1 *Effects:* the same as `basic_ofstream(s.c_str(), mode);`

```
basic_ofstream(basic_ofstream&& rhs);
```

2 *Effects:* Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_filebuf`. Next `basic_ostream<charT,traits>::set_rdbuf(&sb)` is called to install the contained `basic_filebuf`.

27.306.0.1 Assign and swap [ofstream.assign]

```
basic_ofstream& operator=(basic_ofstream&& rhs);
```

1 *Effects:* Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

2 *Returns:* `*this`.

```
void swap(basic_ofstream& rhs);
```

3 *Effects:* Exchanges the state of `*this` and `rhs` by calling `basic_ostream<charT,traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template <class charT, class traits>
void swap(basic_ofstream<charT, traits>& x,
          basic_ofstream<charT, traits>& y);
```

4 *Effects:* `x.swap(y)`.

27.306.0.2 Member functions [ofstream.members]

```
basic_filebuf<charT,traits>* rdbuf() const;
```

1 *Returns:* `const_cast<basic_filebuf<charT,traits>*>(&sb)`.

```
bool is_open() const;
```

2

Returns: `rdbuf()->is_open()`.

```
void open(const char* s, ios_base::openmode mode = ios_base::out);
```

1

Effects: Calls `rdbuf()->open(s, mode | ios_base::out)`. If that function does not return a null pointer calls `clear()`, otherwise calls `setstate(failbit)` (which may throw `ios_base::failure` (27.84.0.1)).

```
void close();
```

1 *Effects:* Calls `rdbuf()->close()` and, if that function fails (returns a null pointer), calls `setstate(failbit)` (which may throw `ios_base::failure` (27.84.0.1)).

```
void open(const string& s, ios_base::openmode mode = ios_base::out);
```

2 *Effects:* calls `open(s.c_str(), mode);`

27.308.0.1 Class template basic_fstream [fstream]

```
namespace std {
  template <class charT, class traits=char_traits<charT> >
  class basic_fstream
    : public basic_iostream<charT,traits> {

  public:
    typedef charT                     char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits                    traits_type;

    // constructors/destructor
    basic_fstream();
    explicit basic_fstream(const char* s,
        ios_base::openmode mode = ios_base::in|ios_base::out);
    explicit basic_fstream(const string& s,
        ios_base::openmode mode = ios_base::in|ios_base::out);
    basic_fstream(const basic_fstream& rhs) = delete;
    basic_fstream(basic_fstream&& rhs);

    // 27.308.0.3 Assign/swap:
    basic_fstream& operator=(const basic_fstream& rhs) = delete;
    basic_fstream& operator=(basic_fstream&& rhs);
    void swap(basic_fstream& rhs);

    // Members:
    basic_filebuf<charT,traits>* rdbuf() const;
    bool is_open() const;
    void open(const char* s,
        ios_base::openmode mode = ios_base::in|ios_base::out);
    void open(const string& s,
        ios_base::openmode mode = ios_base::in|ios_base::out);
    void close();

  private:
    basic_filebuf<charT,traits> sb; // exposition only
  };

  template <class charT, class traits>
  void swap(basic_fstream<charT, traits>& x,
            basic_fstream<charT, traits>& y);
}
```

1 The class template `basic_fstream<charT,traits>` supports reading and writing from named files. It uses a `basic_filebuf<charT,traits>` object to control the associated sequences. For the sake of exposition, the maintained data is presented here as:

(1.1) — `sb`, the `basic_filebuf` object.

27.308.0.2 basic_fstream constructors [fstream.cons]

`basic_fstream();`

1 *Effects:* Constructs an object of class `basic_fstream<charT,traits>`, initializing the base class with `basic_iostream(&sb)` and initializing `sb` with `basic_filebuf<charT,traits>()`.

```
explicit basic_fstream(const char* s,
    ios_base::openmode mode = ios_base::in|ios_base::out);
```

2 *Effects:* Constructs an object of class `basic_fstream<charT, traits>`, initializing the base class with `basic_iostream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()`. Then calls `rdbuf()->open(s, mode)`. If that function returns a null pointer, calls `setstate(failbit)`.

```
explicit basic_fstream(const string& s,
    ios_base::openmode mode = ios_base::in|ios_base::out);
```

3 *Effects:* the same as `basic_fstream(s.c_str(), mode);`

```
basic_fstream(basic_fstream&& rhs);
```

4 *Effects:* Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_filebuf`. Next `basic_istream<charT,traits>::set_rdbuf(&sb)` is called to install the contained `basic_filebuf`.

27.308.0.3 Assign and swap [fstream.assign]

```
basic_fstream& operator=(basic_fstream&& rhs);
```

1 *Effects:* Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

2 *Returns:* `*this`.

```
void swap(basic_fstream& rhs);
```

3 *Effects:* Exchanges the state of `*this` and `rhs` by calling `basic_iostream<charT,traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template <class charT, class traits>
void swap(basic_fstream<charT, traits>& x,
          basic_fstream<charT, traits>& y);
```

4 *Effects:* `x.swap(y)`.

27.308.0.4 Member functions [fstream.members]

```
basic_filebuf<charT,traits>* rdbuf() const;
```

1 *Returns:* `const_cast<basic_filebuf<charT,traits>*>(&sb)`.

```
bool is_open() const;
```

2 *Returns:* `rdbuf()->is_open()`.

```
void open(const char* s,
    ios_base::openmode mode = ios_base::in|ios_base::out);
```

1 *Effects:* Calls `rdbuf()->open(s,mode)`. If that function does not return a null pointer calls `clear()`, otherwise calls `setstate(failbit)`, (which may throw `ios_base::failure`) (27.84.0.1).

```
void open(const string& s,
    ios_base::openmode mode = ios_base::in|ios_base::out);
```

1 *Effects:* calls `open(s.c_str(), mode);`

```
void close();
```

2 *Effects:* Calls `rdbuf()->close()` and, if that function returns returns a null pointer, calls `setstate(failbit)` (27.84.0.1) (which may throw `ios_base::failure`).

27.310.1 C library files [c.files]

1 Table 134 describes header `<cstdio>`. [*Note:* C++ does not define the function `gets`. — *end note*]

Table 134 — Header `<cstdio>` synopsis

Type	Name(s)				
Macros:					
BUFSIZ	FOPEN_MAX	SEEK_CUR	TMP_MAX	_IONBF	stdout
EOF	L_tmpnam	SEEK_END	_IOFBF	stderr	
FILENAME_MAX	NULL <cstdio>	SEEK_SET	_IOLBF	stdin	
Types:	FILE	fpos_t	size_t <cstdio>		
Functions:					
clearerr	fopen	fsetpos	putchar	snprintf	vscanf
fclose	fprintf	ftell	puts	sprintf	vsnprintf
feof	fputc	fwrite	remove	sscanf	vsprintf
ferror	fputs	getc	rename	tmpfile	vsscanf
fflush	fread	getchar	rewind	tmpnam	
fgetc	freopen	perror	scanf	ungetc	
fgetpos	fscanf	printf	setbuf	vfprintf	
fgets	fseek	putc	setvbuf	vprintf	

2 Calls to the function `tmpnam` with an argument of `NULL` may introduce a data race (17.607.0.1) with other calls to `tmpnam` with an argument of `NULL`.

See also: ISO C 7.9, Amendment 1 4.6.2.

3 Table 135 describes header `<cinttypes>`. [*Note:* The macros defined by `<cinttypes>` are provided unconditionally. In particular, the symbol `__STDC_FORMAT_MACROS`, mentioned in footnote 182 of the C standard, plays no role in C++. — *end note*]

Table 135 — Header `<cinttypes>` synopsis

Type	Name(s)		
Macros:			
PRI{d i o u x X}[FAST LEAST]{8 16 32 64}			
PRI{d i o u x X}{MAX PTR}			
SCN{d i o u x X}[FAST LEAST]{8 16 32 64}			
SCN{d i o u x X}{MAX PTR}			
Types:	imaxdiv_t		
Functions:			
abs	imaxabs	strtoimax	wcstoimax
div	imaxdiv	strtoumax	wcstoumax

4

The contents of header `<cinttypes>` are the same as the Standard C Library header `<inttypes.h>`, with the following changes:

— the header `<cinttypes>` includes the header `<cstdint>` instead of `<stdint.h>`, and

— if and only if the type `intmax_t` designates an extended integer type (3.3151.1), the following function signatures are added:

```
intmax_t abs(intmax_t);
imaxdiv_t div(intmax_t, intmax_t);
```

which shall have the same semantics as the function signatures `intmax_t imaxabs(intmax_t)` and `imaxdiv_t imaxdiv(intmax_t, intmax_t)`, respectively.

28 Regular expressions library [re]

28.1 General [re.general]

1 This Clause describes components that C++ programs may use to perform operations involving regular expression matching and searching.

2 The following subclauses describe a basic regular expression class template and its traits that can handle char-like template arguments, two specializations of this class template that handle sequences of `char` and `wchar_t`, a class template that holds the result of a regular expression match, a series of algorithms that allow a character sequence to be operated upon by a regular expression, and two iterator types for enumerating regular expression matches, as described in Table 136.

Table 136 — Regular expressions library summary

Subclause		Header(s)
28.2	Definitions	
28.3	Requirements	
28.8	Constants	
28.24	Exception type	
28.26	Traits	
28.28	Regular expression template	`<regex>`
28.30	Submatches	
28.31	Match results	
28.33	Algorithms	
28.42	Iterators	
28.45	Grammar	

28.2 Definitions [re.def]

1 The following definitions shall apply to this Clause:

28.2.1 [defns.regex.collating.element]

collating element

a sequence of one or more characters within the current locale that collate as if they were a single character.

28.2.2 [defns.regex.finite.state.machine]

finite state machine

an unspecified data structure that is used to represent a regular expression, and which permits efficient matches against the regular expression to be obtained.

28.2.3 [defns.regex.format.specifier]

format specifier

a sequence of one or more characters that is to be replaced with some part of a regular expression match.

28.2.4 [defns.regex.matched]

matched

a sequence of zero or more characters is matched by a regular expression when the characters in the sequence correspond to a sequence of characters defined by the pattern.

28.2.5 **[defns.regex.primary.equivalence.class]**

primary equivalence class

a set of one or more characters which share the same primary sort key: that is the sort key weighting that depends only upon character shape, and not accents, case, or locale specific tailorings.

28.2.6 **[defns.regex.regular.expression]**

regular expression

a pattern that selects specific strings from a set of character strings.

28.2.7 **[defns.regex.subexpression]**

sub-expression

a subset of a regular expression that has been marked by parenthesis.

28.3 Requirements [re.req]

1 This subclause defines requirements on classes representing regular expression traits. [*Note:* The class template `regex_traits`, defined in Clause 28.26, satisfies these requirements. — *end note*]

2 The class template `basic_regex`, defined in Clause 28.28, needs a set of related types and functions to complete the definition of its semantics. These types and functions are provided as a set of member typedefs and functions in the template parameter `traits` used by the `basic_regex` class template. This subclause defines the semantics of these members.

3 To specialize class template `basic_regex` for a character container `CharT` and its related regular expression traits class `Traits`, use `basic_regex<CharT, Traits>`.

4

In Table 137 `X` denotes a traits class defining types and functions for the character container type `charT`; `u` is an object of type `X`; `v` is an object of type `const X`; `p` is a value of type `const charT*`; `I1` and `I2` are input iterators (24.100.1); `F1` and `F2` are forward iterators (24.122.1); `c` is a value of type `const charT`; `s` is an object of type `X::string_type`; `cs` is an object of type `const X::string_type`; `b` is a value of type `bool`; `I` is a value of type `int`; `cl` is an object of type `X::char_class_type`, and `loc` is an object of type `X::locale_type`.

Table 137 — Regular expression traits class requirements

Expression	Return type	Assertion/note pre-/post-condition
`X::char_type`	`charT`	The character container type used in the implementation of class template `basic_regex`.
`X::string_type`	`std::basic_string<charT>`	
`X::locale_type`	A copy constructible type	A type that represents the locale used by the traits class.
`X::char_class_type`	A bitmask type (17.20.0.0.1).	A bitmask type representing a particular character classification.
`X::length(p)`	`std::size_t`	Yields the smallest `i` such that `p[i] == 0`. Complexity is linear in `i` .

Table 137 — Regular expression traits class requirements (continued)

Expression	Return type	Assertion/note pre-/post-condition
`v.translate(c)`	`X::char_type`	Returns a character such that for any character `d` that is to be considered equivalent to `c` then `v.translate(c) == v.translate(d)`.
`v.translate_nocase(c)`	`X::char_type`	For all characters `C` that are to be considered equivalent to `c` when comparisons are to be performed without regard to case, then `v.translate_nocase(c) == v.translate_nocase(C)`.
`v.transform(F1, F2)`	`X::string_type`	Returns a sort key for the character sequence designated by the iterator range `[F1,F2)` such that if the character sequence `[G1,G2)` sorts before the character sequence `[H1,H2)` then `v.transform(G1, G2) < v.transform(H1, H2)`.
`v.transform_primary(F1, F2)`	`X::string_type`	Returns a sort key for the character sequence designated by the iterator range `[F1,F2)` such that if the character sequence `[G1,G2)` sorts before the character sequence `[H1,H2)` when character case is not considered then `v.transform_primary(G1, G2) < v.transform_primary(H1, H2)`.
`v.lookup_collatename(F1, F2)`	`X::string_type`	Returns a sequence of characters that represents the collating element consisting of the character sequence designated by the iterator range `[F1,F2)`. Returns an empty string if the character sequence is not a valid collating element.
`v.lookup_classname(F1, F2, b)`	`X::char_class_type`	Converts the character sequence designated by the iterator range `[F1,F2)` into a value of a bitmask type that can subsequently be passed to `isctype`. Values returned from `lookup_classname` can be bitwise or'ed together; the resulting value represents membership in either of the corresponding character classes. If `b` is true, the returned bitmask is suitable for matching characters without regard to their case. Returns 0 if the character sequence is not the name of a character class recognized by `X`. The value returned shall be independent of the case of the characters in the sequence.
`v.isctype(c, cl)`	`bool`	Returns `true` if character `c` is a member of one of the character classes designated by `cl`, `false` otherwise.

Table 137 — Regular expression traits class requirements (continued)

Expression	Return type	Assertion/note pre-/post-condition
`v.value(c, I)`	`int`	Returns the value represented by the digit c in base I if the character c is a valid digit in base I; otherwise returns `-1`. [*Note:* The value of I will only be 8, 10, or 16. — *end note*]
`u.imbue(loc)`	`X::locale_type`	Imbues `u` with the locale `loc` and returns the previous locale used by `u` if any.
`v.getloc()`	`X::locale_type`	Returns the current locale used by `v`, if any.

1 [*Note:* Class template `regex_traits` satisfies the requirements for a regular expression traits class when it is specialized for `char` or `wchar_t`. This class template is described in the header `<regex>`, and is described in Clause 28.26. — *end note*]

28.7 Header `<regex>` synopsis [re.syn]

```
#include <initializer_list>

  typedef regex_token_iterator<wstring::const_iterator> wsregex_token_iterator;
}
```

28.8 Namespace `std::regex_constants` [re.const]

1 The namespace `std::regex_constants` holds symbolic constants used by the regular expression library. This namespace provides three types, `syntax_option_type`, `match_flag_type`, and `error_type`, along with several constants of these types.

28.8.1 Bitmask type `syntax_option_type` [re.synopt]

```
namespace std {
  namespace regex_constants {
    typedef T1 syntax_option_type;
    constexpr syntax_option_type icase = unspecified ;
    constexpr syntax_option_type nosubs = unspecified ;
    constexpr syntax_option_type optimize = unspecified ;
    constexpr syntax_option_type collate = unspecified ;
    constexpr syntax_option_type ECMAScript = unspecified ;
    constexpr syntax_option_type basic = unspecified ;
    constexpr syntax_option_type extended = unspecified ;
    constexpr syntax_option_type awk = unspecified ;
    constexpr syntax_option_type grep = unspecified ;
    constexpr syntax_option_type egrep = unspecified ;
  }
}
```

1

The type `syntax_option_type` is an implementation-defined bitmask type (17.20.0.0.1). Setting its elements has the effects listed in table 138. A valid value of type `syntax_option_type` shall have at most one of the grammar elements `ECMAScript`, `basic`, `extended`, `awk`, `grep`, `egrep`, set. If no grammar element is set, the default grammar is `ECMAScript`.

28.10.1 Bitmask type `regex_constants::match_flag_type` [re.matchflag]

```
namespace std {
  namespace regex_constants{
    typedef T2 match_flag_type;
    constexpr match_flag_type match_default = {};
    constexpr match_flag_type match_not_bol = unspecified ;
    constexpr match_flag_type match_not_eol = unspecified ;
    constexpr match_flag_type match_not_bow = unspecified ;
    constexpr match_flag_type match_not_eow = unspecified ;
    constexpr match_flag_type match_any = unspecified ;
    constexpr match_flag_type match_not_null = unspecified ;
```

Table 138 — `syntax_option_type` effects

Element	Effect(s) if set
`icase`	Specifies that matching of regular expressions against a character container sequence shall be performed without regard to case.
`nosubs`	Specifies that no sub-expressions shall be considered to be marked, so that when a regular expression is matched against a character container sequence, no sub-expression matches shall be stored in the supplied `match_results` structure.
`optimize`	Specifies that the regular expression engine should pay more attention to the speed with which regular expressions are matched, and less to the speed with which regular expression objects are constructed. Otherwise it has no detectable effect on the program output.
`collate`	Specifies that character ranges of the form `"[a-b]"` shall be locale sensitive.
`ECMAScript`	Specifies that the grammar recognized by the regular expression engine shall be that used by ECMAScript in ECMA-262, as modified in 28.45.
`basic`	Specifies that the grammar recognized by the regular expression engine shall be that used by basic regular expressions in POSIX, Base Definitions and Headers, Section 9, Regular Expressions.
`extended`	Specifies that the grammar recognized by the regular expression engine shall be that used by extended regular expressions in POSIX, Base Definitions and Headers, Section 9, Regular Expressions.
`awk`	Specifies that the grammar recognized by the regular expression engine shall be that used by the utility awk in POSIX.
`grep`	Specifies that the grammar recognized by the regular expression engine shall be that used by the utility grep in POSIX.
`egrep`	Specifies that the grammar recognized by the regular expression engine shall be that used by the utility grep when given the -E option in POSIX.

```
    constexpr match_flag_type match_continuous = unspecified ;
    constexpr match_flag_type match_prev_avail = unspecified ;
    constexpr match_flag_type format_default = {};
    constexpr match_flag_type format_sed = unspecified ;
    constexpr match_flag_type format_no_copy = unspecified ;
    constexpr match_flag_type format_first_only = unspecified ;
  }
}
```

1

The type `regex_constants::match_flag_type` is an implementation-defined bitmask type (17.20.0.0.1). The constants of that type, except for `match_default` and `format_default`, are bitmask elements. The `match_default` and `format_default` constants are empty bitmasks. Matching a regular expression against a sequence of characters `[first,last)` proceeds according to the rules of the grammar specified for the regular expression object, modified according to the effects listed in Table 139 for any bitmask elements set.

Table 139 — `regex_constants::match_flag_type` effects when obtaining a match against a character container sequence `[first, last)`.

Element	Effect(s) if set
`match_not_bol`	The first character in the sequence `[first,last)` shall be treated as though it is not at the beginning of a line, so the character `^` in the regular expression shall not match `[first,first)`.
`match_not_eol`	The last character in the sequence `[first,last)` shall be treated as though it is not at the end of a line, so the character `"$"` in the regular expression shall not match `[last,last)`.
`match_not_bow`	The expression `"\\b"` shall not match the sub-sequence `[first,first)`.
`match_not_eow`	The expression `"\\b"` shall not match the sub-sequence `[last,last)`.
`match_any`	If more than one match is possible then any match is an acceptable result.
`match_not_null`	The expression shall not match an empty sequence.
`match_continuous`	The expression shall only match a sub-sequence that begins at `first`.
`match_prev_avail`	`--first` is a valid iterator position. When this flag is set the flags match_not_bol and match_not_bow shall be ignored by the regular expression algorithms 28.33 and iterators 28.42.
`format_default`	When a regular expression match is to be replaced by a new string, the new string shall be constructed using the rules used by the ECMAScript replace function in ECMA-262, part 15.5.4.11 String.prototype.replace. In addition, during search and replace operations all non-overlapping occurrences of the regular expression shall be located and replaced, and sections of the input that did not match the expression shall be copied unchanged to the output string.
`format_sed`	When a regular expression match is to be replaced by a new string, the new string shall be constructed using the rules used by the sed utility in POSIX.
`format_no_copy`	During a search and replace operation, sections of the character container sequence being searched that do not match the regular expression shall not be copied to the output string.
`format_first_only`	When specified during a search and replace operation, only the first occurrence of the regular expression shall be replaced.

28.19.1 Implementation-defined `error_type` [re.err]

```
namespace std {
  namespace regex_constants {
    typedef T3 error_type;
    constexpr error_type error_collate = unspecified ;
    constexpr error_type error_ctype = unspecified ;
    constexpr error_type error_escape = unspecified ;
    constexpr error_type error_backref = unspecified ;
    constexpr error_type error_brack = unspecified ;
    constexpr error_type error_paren = unspecified ;
    constexpr error_type error_brace = unspecified ;
    constexpr error_type error_badbrace = unspecified ;
    constexpr error_type error_range = unspecified ;
    constexpr error_type error_space = unspecified ;
    constexpr error_type error_badrepeat = unspecified ;
    constexpr error_type error_complexity = unspecified ;
```

```
    constexpr error_type error_stack = unspecified ;
  }
}
```

1

The type `error_type` is an implementation-defined enumerated type (17.17.1.1.2). Values of type `error_type` represent the error conditions described in Table 140:

Table 140 — `error_type` values in the C locale

Value	Error condition
`error_collate`	The expression contained an invalid collating element name.
`error_ctype`	The expression contained an invalid character class name.
`error_escape`	The expression contained an invalid escaped character, or a trailing escape.
`error_backref`	The expression contained an invalid back reference.
`error_brack`	The expression contained mismatched `[` and `]`.
`error_paren`	The expression contained mismatched `(` and `)`.
`error_brace`	The expression contained mismatched `{` and `}`
`error_badbrace`	The expression contained an invalid range in a `{}` expression.
`error_range`	The expression contained an invalid character range, such as `[b-a]` in most encodings.
`error_space`	There was insufficient memory to convert the expression into a finite state machine.
`error_badrepeat`	One of `*?+{` was not preceded by a valid regular expression.
`error_complexity`	The complexity of an attempted match against a regular expression exceeded a pre-set level.
`error_stack`	There was insufficient memory to determine whether the regular expression could match the specified character sequence.

28.24 Class `regex_error` [re.badexp]

```
class regex_error : public std::runtime_error {
  public:
    explicit regex_error(regex_constants::error_type ecode);
    regex_constants::error_type code() const;
};
```

1

The class `regex_error` defines the type of objects thrown as exceptions to report errors from the regular expression library.

`regex_error(regex_constants::error_type ecode);`

1 *Effects:* Constructs an object of class `regex_error`.

2 *Postcondition:*: `ecode == code()`

`regex_constants::error_type code() const;`

3 *Returns:* The error code that was passed to the constructor.

28.26 Class template `regex_traits` [re.traits]

```
namespace std {
  template <class charT>
  struct regex_traits {
  public:
     typedef charT                        char_type;
     typedef std::basic_string<char_type> string_type;
     typedef std::locale                  locale_type;
     typedef bitmask_type                 char_class_type;

     regex_traits();
     static std::size_t length(const char_type* p);
     charT translate(charT c) const;
     charT translate_nocase(charT c) const;
     template <class ForwardIterator>
       string_type transform(ForwardIterator first, ForwardIterator last) const;
     template <class ForwardIterator>
       string_type transform_primary(
         ForwardIterator first, ForwardIterator last) const;
     template <class ForwardIterator>
       string_type lookup_collatename(
         ForwardIterator first, ForwardIterator last) const;
     template <class ForwardIterator>
       char_class_type lookup_classname(
         ForwardIterator first, ForwardIterator last, bool icase = false) const;
     bool isctype(charT c, char_class_type f) const;
     int value(charT ch, int radix) const;
     locale_type imbue(locale_type l);
     locale_type getloc() const;
  };
}
```

1 The specializations `regex_traits<char>` and `regex_traits<wchar_t>` shall be valid and shall satisfy the requirements for a regular expression traits class (28.3).

`typedef bitmask_type  char_class_type;`

2 The type `char_class_type` is used to represent a character classification and is capable of holding an implementation specific set returned by `lookup_classname`.

`static std::size_t length(const char_type* p);`

3 *Returns:* `char_traits<charT>::length(p);`

`charT translate(charT c) const;`

4 *Returns:* `(c)`.

`charT translate_nocase(charT c) const;`

5 *Returns:* `use_facet<ctype<charT> >(getloc()).tolower(c)`.

```
template <class ForwardIterator>
  string_type transform(ForwardIterator first, ForwardIterator last) const;
```

6 *Effects:*

```
string_type str(first, last);
return use_facet<collate<charT> >(
  getloc()).transform(&*str.begin(), &*str.begin() + str.length());
```

```
template <class ForwardIterator>
  string_type transform_primary(ForwardIterator first, ForwardIterator last) const;
```

7 *Effects:* if `typeid(use_facet<collate<charT> >) == typeid(collate_byname<charT>)` and the form of the sort key returned by `collate_byname<charT> ::transform(first, last)` is known and can be converted into a primary sort key then returns that key, otherwise returns an empty string.

```
template <class ForwardIterator>
  string_type lookup_collatename(ForwardIterator first, ForwardIterator last) const;
```

1 *Returns:* a sequence of one or more characters that represents the collating element consisting of the character sequence designated by the iterator range `[first,last)`. Returns an empty string if the character sequence is not a valid collating element.

```
template <class ForwardIterator>
  char_class_type lookup_classname(
    ForwardIterator first, ForwardIterator last, bool icase = false) const;
```

2 *Returns:* an unspecified value that represents the character classification named by the character sequence designated by the iterator range `[first,last)`. If the parameter `icase` is true then the returned mask identifies the character classification without regard to the case of the characters being matched, otherwise it does honor the case of the characters being matched.[335] The value returned shall be independent of the case of the characters in the character sequence. If the name is not recognized then returns `char_class_type()`.

3 *Remarks:* For `regex_traits<char>`, at least the narrow character names in Table 141 shall be recognized. For `regex_traits<wchar_t>`, at least the wide character names in Table 141 shall be recognized.

```
bool isctype(charT c, char_class_type f) const;
```

4 *Effects:* Determines if the character `c` is a member of the character classification represented by `f`.

5 *Returns:* Given the following function prototype:

```
// for exposition only
template<class C>
  ctype_base::mask convert(typename regex_traits<C>::char_class_type f);
```

that returns a value in which each `ctype_base::mask` value corresponding to a value in `f` named in Table 141 is set, then the result is determined as if by:

```
ctype_base::mask m = convert<charT>(f);
const ctype<charT>& ct = use_facet<ctype<charT>>(getloc());
if (ct.is(m, c)) {
  return true;
} else if (c == ct.widen('_')) {
  charT w[1] = { ct.widen('w') };
  char_class_type x = lookup_classname(w, w+1);

  return (f&x) == x;
} else {
  return false;
}
```

[*Example:*

335) For example, if the parameter `icase` is true then `[[:lower:]]` is the same as `[[:alpha:]]`.

```
regex_traits<char> t;
string d("d");
string u("upper");
regex_traits<char>::char_class_type f;
f = t.lookup_classname(d.begin(), d.end());
f |= t.lookup_classname(u.begin(), u.end());
ctype_base::mask m = convert<char>(f); // m == ctype_base::digit|ctype_base::upper
```

— *end example*] [*Example:*

```
regex_traits<char> t;
string w("w");
regex_traits<char>::char_class_type f;
f = t.lookup_classname(w.begin(), w.end());
t.isctype('A', f); // returns true
t.isctype('_', f); // returns true
t.isctype(' ', f); // returns false
```

— *end example*]

`int value(charT ch, int radix) const;`

6 *Requires:* The value of *radix* shall be 8, 10, or 16.

7 *Returns:* the value represented by the digit *ch* in base *radix* if the character *ch* is a valid digit in base *radix*; otherwise returns -1.

`locale_type imbue(locale_type loc);`

8 *Effects:* Imbues `this` with a copy of the locale `loc`. [*Note:* Calling `imbue` with a different locale than the one currently in use invalidates all cached data held by `*this`. — *end note*]

9 *Returns:* if no locale has been previously imbued then a copy of the global locale in effect at the time of construction of `*this`, otherwise a copy of the last argument passed to `imbue`.

10 *Postcondition:* `getloc() == loc`.

`locale_type getloc() const;`

11 *Returns:* if no locale has been imbued then a copy of the global locale in effect at the time of construction of `*this`, otherwise a copy of the last argument passed to `imbue`.

28.28 Class template `basic_regex` [re.regex]

1 For a char-like type `charT`, specializations of class template `basic_regex` represent regular expressions constructed from character sequences of `charT` characters. In the rest of 28.28, `charT` denotes a given char-like type. Storage for a regular expression is allocated and freed as necessary by the member functions of class `basic_regex`.

2

Objects of type specialization of `basic_regex` are responsible for converting the sequence of `charT` objects to an internal representation. It is not specified what form this representation takes, nor how it is accessed by algorithms that operate on regular expressions. [*Note:* Implementations will typically declare some function templates as friends of `basic_regex` to achieve this — *end note*]

1 The functions described in this Clause report errors by throwing exceptions of type `regex_error`.

Table 141 — Character class names and corresponding `ctype` masks

Narrow character name	Wide character name	Corresponding `ctype_base::mask` value
"alnum"	L"alnum"	ctype_base::alnum
"alpha"	L"alpha"	ctype_base::alpha
"blank"	L"blank"	ctype_base::blank
"cntrl"	L"cntrl"	ctype_base::cntrl
"digit"	L"digit"	ctype_base::digit
"d"	L"d"	ctype_base::digit
"graph"	L"graph"	ctype_base::graph
"lower"	L"lower"	ctype_base::lower
"print"	L"print"	ctype_base::print
"punct"	L"punct"	ctype_base::punct
"space"	L"space"	ctype_base::space
"s"	L"s"	ctype_base::space
"upper"	L"upper"	ctype_base::upper
"w"	L"w"	ctype_base::alnum
"xdigit"	L"xdigit"	ctype_base::xdigit

```
namespace std {
  template <class charT,
            class traits = regex_traits<charT> >
  class basic_regex {
  public:
    // types:
    typedef          charT                                value_type;

    // 28.29.5, locale:
    locale_type imbue(locale_type loc);
    locale_type getloc() const;

    // 28.29.6, swap:
    void swap(basic_regex&);
  };
}
```

28.29.1 basic_regex constants [re.regex.const]

```
static constexpr regex_constants::syntax_option_type
  icase = regex_constants::icase;
static constexpr regex_constants::syntax_option_type
  nosubs = regex_constants::nosubs;
static constexpr regex_constants::syntax_option_type
  optimize = regex_constants::optimize;
static constexpr regex_constants::syntax_option_type
  collate = regex_constants::collate;
static constexpr regex_constants::syntax_option_type
  ECMAScript = regex_constants::ECMAScript;
static constexpr regex_constants::syntax_option_type
  basic = regex_constants::basic;
static constexpr regex_constants::syntax_option_type
  extended = regex_constants::extended;
static constexpr regex_constants::syntax_option_type
  awk = regex_constants::awk;
static constexpr regex_constants::syntax_option_type
  grep = regex_constants::grep;
static constexpr regex_constants::syntax_option_type
  egrep = regex_constants::egrep;
```

1 The static constant members are provided as synonyms for the constants declared in namespace `regex_constants`.

28.29.2 `basic_regex` constructors [re.regex.construct]

`basic_regex();`

1 *Effects:* Constructs an object of class `basic_regex` that does not match any character sequence.

`explicit basic_regex(const charT* p, flag_type f = regex_constants::ECMAScript);`

2 *Requires:* p shall not be a null pointer.

3 *Throws:* `regex_error` if p is not a valid regular expression.

4 *Effects:* Constructs an object of class `basic_regex`; the object's internal finite state machine is constructed from the regular expression contained in the array of `charT` of length `char_traits<charT>::length(p)` whose first element is designated by p, and interpreted according to the flags f.

5 *Postconditions:* `flags()` returns `f`. `mark_count()` returns the number of marked sub-expressions within the expression.

`basic_regex(const charT* p, size_t len, flag_type f);`

6 *Requires:* p shall not be a null pointer.

7 *Throws:* `regex_error` if p is not a valid regular expression.

8 *Effects:* Constructs an object of class `basic_regex`; the object's internal finite state machine is constructed from the regular expression contained in the sequence of characters `[p,p+len)`, and interpreted according the flags specified in f.

9 *Postconditions:* `flags()` returns `f`. `mark_count()` returns the number of marked sub-expressions within the expression.

`basic_regex(const basic_regex& e);`

10 *Effects:* Constructs an object of class `basic_regex` as a copy of the object `e`.

11 *Postconditions:* `flags()` and `mark_count()` return `e.flags()` and `e.mark_count()`, respectively.

```
basic_regex(basic_regex&& e) noexcept;
```

12 *Effects:* Move constructs an object of class `basic_regex` from `e`.

13 *Postconditions:* `flags()` and `mark_count()` return the values that `e.flags()` and `e.mark_count()`, respectively, had before construction. `e` is in a valid state with unspecified value.

```
template <class ST, class SA>
  explicit basic_regex(const basic_string<charT, ST, SA>& s,
                       flag_type f = regex_constants::ECMAScript);
```

14 *Throws:* `regex_error` if `s` is not a valid regular expression.

15 *Effects:* Constructs an object of class `basic_regex`; the object's internal finite state machine is constructed from the regular expression contained in the string `s`, and interpreted according to the flags specified in `f`.

16 *Postconditions:* `flags()` returns `f`. `mark_count()` returns the number of marked sub-expressions within the expression.

```
template <class ForwardIterator>
  basic_regex(ForwardIterator first, ForwardIterator last,
              flag_type f = regex_constants::ECMAScript);
```

17 *Throws:* `regex_error` if the sequence `[first,last)` is not a valid regular expression.

18 *Effects:* Constructs an object of class `basic_regex`; the object's internal finite state machine is constructed from the regular expression contained in the sequence of characters `[first,last)`, and interpreted according to the flags specified in `f`.

19 *Postconditions:* `flags()` returns `f`. `mark_count()` returns the number of marked sub-expressions within the expression.

```
basic_regex(initializer_list<charT> il,
            flag_type f = regex_constants::ECMAScript);
```

20 *Effects:* Same as `basic_regex(il.begin(), il.end(), f)`.

28.29.3 `basic_regex` assign [re.regex.assign]

```
basic_regex& operator=(const basic_regex& e);
```

1 *Effects:* returns `assign(e)`.

```
basic_regex& operator=(basic_regex&& e) noexcept;
```

2 *Effects:* returns `assign(std::move(e))`.

```
basic_regex& operator=(const charT* ptr);
```

3 *Requires:* `ptr` shall not be a null pointer.

4 *Effects:* returns `assign(ptr)`.

```
basic_regex& operator=(initializer_list<charT> il);
```

5 *Effects:* returns `assign(il.begin(), il.end())`.

```
template <class ST, class SA>
  basic_regex& operator=(const basic_string<charT, ST, SA>& p);
```

6 *Effects:* returns `assign(p)`.

```
basic_regex& assign(const basic_regex& that);
```

7 *Effects:* copies `that` into `*this` and returns `*this`.

8 *Postconditions:* `flags()` and `mark_count()` return `that.flags()` and `that.mark_count()`, respectively.

```
basic_regex& assign(basic_regex&& that) noexcept;
```

9 *Effects:* move assigns from `that` into `*this` and returns `*this`.

10 *Postconditions:* `flags()` and `mark_count()` return the values that `that.flags()` and `that.mark_count()`, respectively, had before assignment. `that` is in a valid state with unspecified value.

```
basic_regex& assign(const charT* ptr, flag_type f = regex_constants::ECMAScript);
```

11 *Returns:* `assign(string_type(ptr), f)`.

```
basic_regex& assign(const charT* ptr, size_t len,
  flag_type f = regex_constants::ECMAScript);
```

12 *Returns:* `assign(string_type(ptr, len), f)`.

```
template <class string_traits, class A>
  basic_regex& assign(const basic_string<charT, string_traits, A>& s,
                      flag_type f = regex_constants::ECMAScript);
```

13 *Throws:* `regex_error` if `s` is not a valid regular expression.

14 *Returns:* `*this`.

15 *Effects:* Assigns the regular expression contained in the string `s`, interpreted according the flags specified in `f`. If an exception is thrown, `*this` is unchanged.

16 *Postconditions:* If no exception is thrown, `flags()` returns `f` and `mark_count()` returns the number of marked sub-expressions within the expression.

```
template <class InputIterator>
  basic_regex& assign(InputIterator first, InputIterator last,
                      flag_type f = regex_constants::ECMAScript);
```

17 *Requires:* The type `InputIterator` shall satisfy the requirements for an Input Iterator (24.100.1).

18 *Returns:* `assign(string_type(first, last), f)`.

```
basic_regex& assign(initializer_list<charT> il,
                    flag_type f = regex_constants::ECMAScript);
```

19 *Effects:* Same as `assign(il.begin(), il.end(), f)`.

20 *Returns:* `*this`.

28.29.4 `basic_regex` constant operations [re.regex.operations]

```
unsigned mark_count() const;
```

1 *Effects:* Returns the number of marked sub-expressions within the regular expression.

```
flag_type flags() const;
```

2 *Effects:* Returns a copy of the regular expression syntax flags that were passed to the object's constructor or to the last call to `assign`.

28.29.5 basic_regex locale [re.regex.locale]

`locale_type imbue(locale_type loc);`

1 *Effects:* Returns the result of `traits_inst.imbue(loc)` where `traits_inst` is a (default initialized) instance of the template type argument `traits` stored within the object. After a call to `imbue` the `basic_regex` object does not match any character sequence.

`locale_type getloc() const;`

2 *Effects:* Returns the result of `traits_inst.getloc()` where `traits_inst` is a (default initialized) instance of the template parameter `traits` stored within the object.

28.29.6 basic_regex swap [re.regex.swap]

`void swap(basic_regex& e);`

1 *Effects:* Swaps the contents of the two regular expressions.

2 *Postcondition:* `*this` contains the regular expression that was in `e`, `e` contains the regular expression that was in `*this`.

3 *Complexity:* Constant time.

28.29.7 basic_regex non-member functions [re.regex.nonmemb]

28.29.7.1 basic_regex non-member swap [re.regex.nmswap]

```
template <class charT, class traits>
  void swap(basic_regex<charT, traits>& lhs, basic_regex<charT, traits>& rhs);
```

1 *Effects:* Calls `lhs.swap(rhs)`.

28.30 Class template sub_match [re.submatch]

1 Class template `sub_match` denotes the sequence of characters matched by a particular marked sub-expression.

```
namespace std {
  template <class BidirectionalIterator>
  class sub_match : public std::pair<BidirectionalIterator, BidirectionalIterator> {
  public:
     typedef typename iterator_traits<BidirectionalIterator>::
       value_type                                          value_type;
     typedef typename iterator_traits<BidirectionalIterator>::
       difference_type                                     difference_type;
     typedef BidirectionalIterator                         iterator;
     typedef basic_string<value_type>                      string_type;

     bool matched;

     constexpr sub_match();

     difference_type length() const;
     operator string_type() const;
     string_type str() const;

     int compare(const sub_match& s) const;
     int compare(const string_type& s) const;
     int compare(const value_type* s) const;
  };
}
```

28.30.1 sub_match members [re.submatch.members]

```
constexpr sub_match();
```

1 *Effects:* Value-initializes the `pair` base class subobject and the member `matched`.

```
difference_type length() const;
```

2 *Returns:* `(matched ? distance(first, second) : 0)`.

```
operator string_type() const;
```

3 *Returns:* `matched ? string_type(first, second) : string_type()`.

```
string_type str() const;
```

4 *Returns:* `matched ? string_type(first, second) : string_type()`.

```
int compare(const sub_match& s) const;
```

5 *Returns:* `str().compare(s.str())`.

```
int compare(const string_type& s) const;
```

6 *Returns:* `str().compare(s)`.

```
int compare(const value_type* s) const;
```

7 *Returns:* `str().compare(s)`.

28.30.2 sub_match non-member operators [re.submatch.op]

```
template <class BiIter>
  bool operator==(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
```

1 *Returns:* `lhs.compare(rhs) == 0`.

```
template <class BiIter>
  bool operator!=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
```

2 *Returns:* `lhs.compare(rhs) != 0`.

```
template <class BiIter>
  bool operator<(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
```

3 *Returns:* `lhs.compare(rhs) < 0`.

```
template <class BiIter>
  bool operator<=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
```

4 *Returns:* `lhs.compare(rhs) <= 0`.

```
template <class BiIter>
  bool operator>=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
```

5 *Returns:* `lhs.compare(rhs) >= 0`.

```
template <class BiIter>
  bool operator>(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
```

6 *Returns:* `lhs.compare(rhs) > 0`.

```
template <class BiIter, class ST, class SA>
  bool operator==(
    const basic_string<
      typename iterator_traits<BiIter>::value_type, ST, SA>& lhs,
    const sub_match<BiIter>& rhs);
```

7 *Returns:* `rhs.compare(lhs.c_str()) == 0`.

```
template <class BiIter, class ST, class SA>
  bool operator!=(
    const basic_string<
      typename iterator_traits<BiIter>::value_type, ST, SA>& lhs,
    const sub_match<BiIter>& rhs);
```

8 *Returns:* `!(lhs == rhs)`.

```
template <class BiIter, class ST, class SA>
  bool operator<(
    const basic_string<
      typename iterator_traits<BiIter>::value_type, ST, SA>& lhs,
    const sub_match<BiIter>& rhs);
```

9 *Returns:* `rhs.compare(lhs.c_str()) > 0`.

```
template <class BiIter, class ST, class SA>
  bool operator>(
    const basic_string<
      typename iterator_traits<BiIter>::value_type, ST, SA>& lhs,
    const sub_match<BiIter>& rhs);
```

10 *Returns:* `rhs < lhs`.

```
template <class BiIter, class ST, class SA>
  bool operator>=(
    const basic_string<
      typename iterator_traits<BiIter>::value_type, ST, SA>& lhs,
    const sub_match<BiIter>& rhs);
```

11 *Returns:* `!(lhs < rhs)`.

```
template <class BiIter, class ST, class SA>
  bool operator<=(
    const basic_string<
      typename iterator_traits<BiIter>::value_type, ST, SA>& lhs,
    const sub_match<BiIter>& rhs);
```

12 *Returns:* `!(rhs < lhs)`.

```
template <class BiIter, class ST, class SA>
  bool operator==(const sub_match<BiIter>& lhs,
                  const basic_string<
                    typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);
```

13 *Returns:* `lhs.compare(rhs.c_str()) == 0`.

```
template <class BiIter, class ST, class SA>
  bool operator!=(const sub_match<BiIter>& lhs,
                  const basic_string<
                    typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);
```

14 *Returns:* `!(lhs == rhs)`.

```
template <class BiIter, class ST, class SA>
  bool operator<(const sub_match<BiIter>& lhs,
                 const basic_string<
                   typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);
```

15 *Returns:* `lhs.compare(rhs.c_str()) < 0`.

```
template <class BiIter, class ST, class SA>
  bool operator>(const sub_match<BiIter>& lhs,
                 const basic_string<
                   typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);
```

16 *Returns:* `rhs < lhs`.

```
template <class BiIter, class ST, class SA>
  bool operator>=(const sub_match<BiIter>& lhs,
                  const basic_string<
                    typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);
```

17 *Returns:* `!(lhs < rhs)`.

```
template <class BiIter, class ST, class SA>
  bool operator<=(const sub_match<BiIter>& lhs,
                  const basic_string<
                    typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);
```

18 *Returns:* `!(rhs < lhs)`.

```
template <class BiIter>
  bool operator==(typename iterator_traits<BiIter>::value_type const* lhs,
                  const sub_match<BiIter>& rhs);
```

19 *Returns:* `rhs.compare(lhs) == 0`.

```
template <class BiIter>
  bool operator!=(typename iterator_traits<BiIter>::value_type const* lhs,
                  const sub_match<BiIter>& rhs);
```

20 *Returns:* `!(lhs == rhs)`.

```
template <class BiIter>
  bool operator<(typename iterator_traits<BiIter>::value_type const* lhs,
                 const sub_match<BiIter>& rhs);
```

21 *Returns:* `rhs.compare(lhs) > 0`.

```
template <class BiIter>
  bool operator>(typename iterator_traits<BiIter>::value_type const* lhs,
                 const sub_match<BiIter>& rhs);
```

22 *Returns:* `rhs < lhs`.

```
template <class BiIter>
  bool operator>=(typename iterator_traits<BiIter>::value_type const* lhs,
                  const sub_match<BiIter>& rhs);
```

23 *Returns:* `!(lhs < rhs)`.

```
template <class BiIter>
  bool operator<=(typename iterator_traits<BiIter>::value_type const* lhs,
                  const sub_match<BiIter>& rhs);
```

24 *Returns:* `!(rhs < lhs)`.

```
template <class BiIter>
  bool operator==(const sub_match<BiIter>& lhs,
                  typename iterator_traits<BiIter>::value_type const* rhs);
```

25 *Returns:* `lhs.compare(rhs) == 0`.

```
template <class BiIter>
  bool operator!=(const sub_match<BiIter>& lhs,
                  typename iterator_traits<BiIter>::value_type const* rhs);
```

26 *Returns:* `!(lhs == rhs)`.

```
template <class BiIter>
  bool operator<(const sub_match<BiIter>& lhs,
                 typename iterator_traits<BiIter>::value_type const* rhs);
```

27 *Returns:* `lhs.compare(rhs) < 0`.

```
template <class BiIter>
  bool operator>(const sub_match<BiIter>& lhs,
                 typename iterator_traits<BiIter>::value_type const* rhs);
```

28 *Returns:* `rhs < lhs`.

```
template <class BiIter>
  bool operator>=(const sub_match<BiIter>& lhs,
                  typename iterator_traits<BiIter>::value_type const* rhs);
```

29 *Returns:* `!(lhs < rhs)`.

```
template <class BiIter>
  bool operator<=(const sub_match<BiIter>& lhs,
                  typename iterator_traits<BiIter>::value_type const* rhs);
```

30 *Returns:* `!(rhs < lhs)`.

```
template <class BiIter>
  bool operator==(typename iterator_traits<BiIter>::value_type const& lhs,
                  const sub_match<BiIter>& rhs);
```

31 *Returns:* `rhs.compare(typename sub_match<BiIter>::string_type(1, lhs)) == 0`.

```
template <class BiIter>
  bool operator!=(typename iterator_traits<BiIter>::value_type const& lhs,
                  const sub_match<BiIter>& rhs);
```

32 *Returns:* `!(lhs == rhs)`.

```
template <class BiIter>
  bool operator<(typename iterator_traits<BiIter>::value_type const& lhs,
                 const sub_match<BiIter>& rhs);
```

33 *Returns:* `rhs.compare(typename sub_match<BiIter>::string_type(1, lhs)) > 0`.

```
template <class BiIter>
  bool operator>(typename iterator_traits<BiIter>::value_type const& lhs,
                 const sub_match<BiIter>& rhs);
```

34 *Returns:* `rhs < lhs`.

```
template <class BiIter>
  bool operator>=(typename iterator_traits<BiIter>::value_type const& lhs,
                  const sub_match<BiIter>& rhs);
```

35 *Returns:* `!(lhs < rhs)`.

```
template <class BiIter>
  bool operator<=(typename iterator_traits<BiIter>::value_type const& lhs,
                  const sub_match<BiIter>& rhs);
```

36 *Returns:* `!(rhs < lhs)`.

```
template <class BiIter>
  bool operator==(const sub_match<BiIter>& lhs,
                  typename iterator_traits<BiIter>::value_type const& rhs);
```

37 *Returns:* `lhs.compare(typename sub_match<BiIter>::string_type(1, rhs)) == 0`.

```
template <class BiIter>
  bool operator!=(const sub_match<BiIter>& lhs,
                  typename iterator_traits<BiIter>::value_type const& rhs);
```

38 *Returns:* `!(lhs == rhs)`.

```
template <class BiIter>
  bool operator<(const sub_match<BiIter>& lhs,
                 typename iterator_traits<BiIter>::value_type const& rhs);
```

39 *Returns:* `lhs.compare(typename sub_match<BiIter>::string_type(1, rhs)) < 0`.

```
template <class BiIter>
  bool operator>(const sub_match<BiIter>& lhs,
                 typename iterator_traits<BiIter>::value_type const& rhs);
```

40 *Returns:* `rhs < lhs`.

```
template <class BiIter>
  bool operator>=(const sub_match<BiIter>& lhs,
                  typename iterator_traits<BiIter>::value_type const& rhs);
```

41 *Returns:* `!(lhs < rhs)`.

```
template <class BiIter>
  bool operator<=(const sub_match<BiIter>& lhs,
                  typename iterator_traits<BiIter>::value_type const& rhs);
```

42 *Returns:* `!(rhs < lhs)`.

```
template <class charT, class ST, class BiIter>
  basic_ostream<charT, ST>&
  operator<<(basic_ostream<charT, ST>& os, const sub_match<BiIter>& m);
```

43 *Returns:* `(os << m.str())`.

28.31 Class template match_results [re.results]

1 Class template `match_results` denotes a collection of character sequences representing the result of a regular expression match. Storage for the collection is allocated and freed as necessary by the member functions of class template `match_results`.

2 The class template `match_results` shall satisfy the requirements of an allocator-aware container and of a sequence container, as specified in 23.224.1, except that only operations defined for const-qualified sequence containers are supported.

3 A default-constructed `match_results` object has no fully established result state. A match result is *ready* when, as a consequence of a completed regular expression match modifying such an object, its result state becomes fully established. The effects of calling most member functions from a `match_results` object that is not ready are undefined.

4 The `sub_match` object stored at index 0 represents sub-expression 0, i.e., the whole match. In this case the `sub_match` member `matched` is always true. The `sub_match` object stored at index `n` denotes what matched the marked sub-expression `n` within the matched expression. If the sub-expression `n` participated in a regular expression match then the `sub_match` member `matched` evaluates to true, and members `first` and `second` denote the range of characters `[first,second)` which formed that match. Otherwise `matched` is false, and members `first` and `second` point to the end of the sequence that was searched. [*Note:* The `sub_match` objects representing different sub-expressions that did not participate in a regular expression match need not be distinct. — *end note*]

```
namespace std {
  template <class BidirectionalIterator,
            class Allocator = allocator<sub_match<BidirectionalIterator>>>
  class match_results {
  public:
     typedef sub_match<BidirectionalIterator>                      value_type;
     typedef const value_type&                                     const_reference;
     typedef value_type&                                           reference;
     typedef implementation-defined                                const_iterator;
     typedef const_iterator                                        iterator;
     typedef typename
      iterator_traits<BidirectionalIterator>::difference_type      difference_type;
     typedef typename allocator_traits<Allocator>::size_type       size_type;
     typedef Allocator                                             allocator_type;
     typedef typename iterator_traits<BidirectionalIterator>::
       value_type                                                  char_type;
     typedef basic_string<char_type>                               string_type;

     // 28.31.1, construct/copy/destroy:
     explicit match_results(const Allocator& a = Allocator());
     match_results(const match_results& m);
     match_results(match_results&& m) noexcept;
     match_results& operator=(const match_results& m);
     match_results& operator=(match_results&& m);
     ~match_results();

     // 28.32.1, state:
     bool ready() const;

     // 28.32.2, size:
     size_type size() const;
     size_type max_size() const;
     bool empty() const;
```

```
    // 28.32.3, element access:
    difference_type length(size_type sub = 0) const;
    difference_type position(size_type sub = 0) const;
    string_type str(size_type sub = 0) const;
    const_reference operator[](size_type n) const;

    const_reference prefix() const;
    const_reference suffix() const;
    const_iterator begin() const;
    const_iterator end() const;
    const_iterator cbegin() const;
    const_iterator cend() const;

    // 28.32.4, format:
    template <class OutputIter>
     OutputIter
     format(OutputIter out,
            const char_type* fmt_first, const char_type* fmt_last,
            regex_constants::match_flag_type flags =
             regex_constants::format_default) const;
    template <class OutputIter, class ST, class SA>
      OutputIter
      format(OutputIter out,
             const basic_string<char_type, ST, SA>& fmt,
             regex_constants::match_flag_type flags =
               regex_constants::format_default) const;
    template <class ST, class SA>
     basic_string<char_type, ST, SA>
     format(const basic_string<char_type, ST, SA>& fmt,
            regex_constants::match_flag_type flags =
              regex_constants::format_default) const;
    string_type
    format(const char_type* fmt,
           regex_constants::match_flag_type flags =
             regex_constants::format_default) const;

    // 28.32.5, allocator:
    allocator_type get_allocator() const;

    // 28.32.6, swap:
    void swap(match_results& that);
  };
}
```

28.31.1 `match_results` constructors [re.results.const]

1

In all `match_results` constructors, a copy of the `Allocator` argument shall be used for any memory allocation performed by the constructor or member functions during the lifetime of the object.

`match_results(const Allocator& a = Allocator());`

1 *Effects:* Constructs an object of class `match_results`.

2 *Postconditions:* `ready()` returns `false`. `size()` returns `0`.

`match_results(const match_results& m);`

3 *Effects:* Constructs an object of class `match_results`, as a copy of `m`.

`match_results(match_results&& m) noexcept;`

4 *Effects:* Move-constructs an object of class `match_results` from `m` satisfying the same postconditions as Table 142. Additionally, the stored `Allocator` value is move constructed from `m.get_allocator()`.

5 *Throws:* Nothing.

`match_results& operator=(const match_results& m);`

6 *Effects:* Assigns `m` to `*this`. The postconditions of this function are indicated in Table 142.

`match_results& operator=(match_results&& m);`

7 *Effects:* Move-assigns `m` to `*this`. The postconditions of this function are indicated in Table 142.

Table 142 — `match_results` assignment operator effects

Element	Value
`ready()`	`m.ready()`
`size()`	`m.size()`
`str(n)`	`m.str(n)` for all integers `n < m.size()`
`prefix()`	`m.prefix()`
`suffix()`	`m.suffix()`
`(*this)[n]`	`m[n]` for all integers `n < m.size()`
`length(n)`	`m.length(n)` for all integers `n < m.size()`
`position(n)`	`m.position(n)` for all integers `n < m.size()`

28.32.1 `match_results` state [re.results.state]

`bool ready() const;`

1 *Returns:* `true` if `*this` has a fully established result state, otherwise `false`.

28.32.2 `match_results` size [re.results.size]

`size_type size() const;`

1 *Returns:* One plus the number of marked sub-expressions in the regular expression that was matched if `*this` represents the result of a successful match. Otherwise returns `0`. [*Note:* The state of a `match_results` object can be modified only by passing that object to `regex_match` or `regex_search`. Sections 28.35.1 and 28.37.1 specify the effects of those algorithms on their `match_results` arguments. — *end note*]

`size_type max_size() const;`

2 *Returns:* The maximum number of `sub_match` elements that can be stored in `*this`.

`bool empty() const;`

3 *Returns:* `size() == 0`.

28.32.3 `match_results` element access [re.results.acc]

`difference_type length(size_type sub = 0) const;`

1 *Requires:* `ready() == true`.

2 *Returns:* `(*this)[sub].length()`.

`difference_type position(size_type sub = 0) const;`

3 *Requires:* `ready() == true`.

4 *Returns:* The distance from the start of the target sequence to `(*this)[sub].first`.

`string_type str(size_type sub = 0) const;`

5 *Requires:* `ready() == true`.

6 *Returns:* `string_type((*this)[sub])`.

`const_reference operator[](size_type n) const;`

7 *Requires:* `ready() == true`.

8 *Returns:* A reference to the `sub_match` object representing the character sequence that matched marked sub-expression `n`. If `n == 0` then returns a reference to a `sub_match` object representing the character sequence that matched the whole regular expression. If `n >= size()` then returns a `sub_match` object representing an unmatched sub-expression.

`const_reference prefix() const;`

9 *Requires:* `ready() == true`.

10 *Returns:* A reference to the `sub_match` object representing the character sequence from the start of the string being matched/searched to the start of the match found.

`const_reference suffix() const;`

11 *Requires:* `ready() == true`.

12 *Returns:* A reference to the `sub_match` object representing the character sequence from the end of the match found to the end of the string being matched/searched.

```
const_iterator begin() const;
const_iterator cbegin() const;
```

13 *Returns:* A starting iterator that enumerates over all the sub-expressions stored in `*this`.

```
const_iterator end() const;
const_iterator cend() const;
```

14 *Returns:* A terminating iterator that enumerates over all the sub-expressions stored in `*this`.

28.32.4 `match_results` formatting [re.results.form]

```
template <class OutputIter>
  OutputIter format(OutputIter out,
                    const char_type* fmt_first, const char_type* fmt_last,
                    regex_constants::match_flag_type flags =
                      regex_constants::format_default) const;
```

1 *Requires:* ready() == true and `OutputIter` shall satisfy the requirements for an Output Iterator (24.116.1).

2 *Effects:* Copies the character sequence `[fmt_first,fmt_last)` to OutputIter `out`. Replaces each format specifier or escape sequence in the copied range with either the character(s) it represents or the sequence of characters within `*this` to which it refers. The bitmasks specified in `flags` determine which format specifiers and escape sequences are recognized.

3 *Returns:* `out`.

```
template <class OutputIter, class ST, class SA>
  OutputIter format(OutputIter out,
                    const basic_string<char_type, ST, SA>& fmt,
                    regex_constants::match_flag_type flags =
                      regex_constants::format_default) const;
```

4 *Effects:* Equivalent to `return format(out, fmt.data(), fmt.data() + fmt.size(), flags)`.

```
template <class ST, class SA>
  basic_string<char_type, ST, SA>
  format(const basic_string<char_type, ST, SA>& fmt,
         regex_constants::match_flag_type flags =
           regex_constants::format_default) const;
```

5 *Requires:* `ready() == true`.

6 *Effects:* Constructs an empty string `result` of type `basic_string<char_type, ST, SA>` and calls `format(back_inserter(result), fmt, flags)`.

7 *Returns:* `result`.

```
string_type
  format(const char_type* fmt,
         regex_constants::match_flag_type flags =
           regex_constants::format_default) const;
```

8 *Requires:* `ready() == true`.

9 *Effects:* Constructs an empty string `result` of type `string_type` and calls `format(back_inserter(result), fmt, fmt + char_traits<char_type>::length(fmt), flags)`.

10 *Returns:* `result`.

28.32.5 `match_results` allocator [re.results.all]

```
allocator_type get_allocator() const;
```

1 *Returns:* A copy of the Allocator that was passed to the object's constructor or, if that allocator has been replaced, a copy of the most recent replacement.

28.32.6 `match_results` swap [re.results.swap]

```
void swap(match_results& that);
```

1 *Effects:* Swaps the contents of the two sequences.

2 *Postcondition:* `*this` contains the sequence of matched sub-expressions that were in `that`, `that` contains the sequence of matched sub-expressions that were in `*this`.

3 *Complexity:* Constant time.

```
template <class BidirectionalIterator, class Allocator>
  void swap(match_results<BidirectionalIterator, Allocator>& m1,
            match_results<BidirectionalIterator, Allocator>& m2);
```

4 *Effects:* `m1.swap(m2)`.

28.32.7 `match_results` non-member functions [re.results.nonmember]

```
template <class BidirectionalIterator, class Allocator>
bool operator==(const match_results<BidirectionalIterator, Allocator>& m1,
                const match_results<BidirectionalIterator, Allocator>& m2);
```

1 *Returns:* `true` if neither match result is ready, `false` if one match result is ready and the other is not. If both match results are ready, returns `true` only if:

(1.1) — `m1.empty() && m2.empty()`, or

(1.2) — `!m1.empty() && !m2.empty()`, and the following conditions are satisfied:

(1.2.1) — `m1.prefix() == m2.prefix()`,

(1.2.2) — `m1.size() == m2.size() && equal(m1.begin(), m1.end(), m2.begin())`, and

(1.2.3) — `m1.suffix() == m2.suffix()`.

[*Note:* The algorithm `equal` is defined in Clause 25. — *end note*]

```
template <class BidirectionalIterator, class Allocator>
bool operator!=(const match_results<BidirectionalIterator, Allocator>& m1,
                const match_results<BidirectionalIterator, Allocator>& m2);
```

2 *Returns:* `!(m1 == m2)`.

28.33 Regular expression algorithms [re.alg]

28.33.1 exceptions [re.except]

1

The algorithms described in this subclause may throw an exception of type `regex_error`. If such an exception `e` is thrown, `e.code()` shall return either `regex_constants::error_complexity` or `regex_constants::error_stack`.

28.35.1 `regex_match` [re.alg.match]

```
template <class BidirectionalIterator, class Allocator, class charT, class traits>
  bool regex_match(BidirectionalIterator first, BidirectionalIterator last,
                   match_results<BidirectionalIterator, Allocator>& m,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags =
                     regex_constants::match_default);
```

1 *Requires:* The type `BidirectionalIterator` shall satisfy the requirements of a Bidirectional Iterator (24.165.1).

2

Effects: Determines whether there is a match between the regular expression `e`, and all of the character sequence `[first,last)`. The parameter `flags` is used to control how the expression is matched against the character sequence. Returns `true` if such a match exists, `false` otherwise.

1

Postconditions: `m.ready() == true` in all cases. If the function returns `false`, then the effect on parameter `m` is unspecified except that `m.size()` returns `0` and `m.empty()` returns `true`. Otherwise the effects on parameter `m` are given in Table 143.

Table 143 — Effects of `regex_match` algorithm

Element	Value
`m.size()`	`1 + e.mark_count()`
`m.empty()`	false
`m.prefix().first`	first
`m.prefix().second`	first
`m.prefix().matched`	false
`m.suffix().first`	last
`m.suffix().second`	last
`m.suffix().matched`	false
`m[0].first`	first
`m[0].second`	last
`m[0].matched`	`true`
`m[n].first`	For all integers `0 < n < m.size()`, the start of the sequence that matched sub-expression `n`. Alternatively, if sub-expression `n` did not participate in the match, then `last`.
`m[n].second`	For all integers `0 < n < m.size()`, the end of the sequence that matched sub-expression `n`. Alternatively, if sub-expression `n` did not participate in the match, then `last`.
`m[n].matched`	For all integers `0 < n < m.size()`, `true` if sub-expression `n` participated in the match, `false` otherwise.

```
template <class BidirectionalIterator, class charT, class traits>
  bool regex_match(BidirectionalIterator first, BidirectionalIterator last,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags =
                     regex_constants::match_default);
```

1 *Effects:* Behaves "as if" by constructing an instance of `match_results<BidirectionalIterator> what`, and then returning the result of `regex_match(first, last, what, e, flags)`.

```
template <class charT, class Allocator, class traits>
  bool regex_match(const charT* str,
                   match_results<const charT*, Allocator>& m,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags =
                     regex_constants::match_default);
```

2 *Returns:* `regex_match(str, str + char_traits<charT>::length(str), m, e, flags)`.

```
template <class ST, class SA, class Allocator, class charT, class traits>
  bool regex_match(const basic_string<charT, ST, SA>& s,
                   match_results<
                     typename basic_string<charT, ST, SA>::const_iterator,
                     Allocator>& m,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags =
                     regex_constants::match_default);
```

3 *Returns:* `regex_match(s.begin(), s.end(), m, e, flags)`.

```
template <class charT, class traits>
  bool regex_match(const charT* str,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags =
                     regex_constants::match_default);
```

4 *Returns:* `regex_match(str, str + char_traits<charT>::length(str), e, flags)`

```
template <class ST, class SA, class charT, class traits>
  bool regex_match(const basic_string<charT, ST, SA>& s,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags =
                     regex_constants::match_default);
```

5 *Returns:* `regex_match(s.begin(), s.end(), e, flags)`.

28.37.1 `regex_search` [re.alg.search]

```
template <class BidirectionalIterator, class Allocator, class charT, class traits>
  bool regex_search(BidirectionalIterator first, BidirectionalIterator last,
                    match_results<BidirectionalIterator, Allocator>& m,
                    const basic_regex<charT, traits>& e,
                    regex_constants::match_flag_type flags =
                      regex_constants::match_default);
```

1

Requires: Type `BidirectionalIterator` shall satisfy the requirements of a Bidirectional Iterator (24.165.1).

1

Effects: Determines whether there is some sub-sequence within `[first,last)` that matches the regular expression `e`. The parameter `flags` is used to control how the expression is matched against the character sequence. Returns `true` if such a sequence exists, `false` otherwise.

1 *Postconditions:* `m.ready() == true` in all cases. If the function returns `false`, then the effect on parameter `m` is unspecified except that `m.size()` returns `0` and `m.empty()` returns `true`. Otherwise the effects on parameter `m` are given in Table 144.

Table 144 — Effects of `regex_search` algorithm

Element	Value
`m.size()`	`1 + e.mark_count()`
`m.empty()`	`false`
`m.prefix().first`	`first`
`m.prefix().second`	`m[0].first`
`m.prefix().matched`	`m.prefix().first != m.prefix().second`
`m.suffix().first`	`m[0].second`
`m.suffix().second`	`last`
`m.suffix().matched`	`m.suffix().first != m.suffix().second`
`m[0].first`	The start of the sequence of characters that matched the regular expression
`m[0].second`	The end of the sequence of characters that matched the regular expression
`m[0].matched`	`true`

Table 144 — Effects of `regex_search` algorithm (continued)

Element	Value
`m[n].first`	For all integers `0 < n < m.size()`, the start of the sequence that matched sub-expression `n`. Alternatively, if sub-expression `n` did not participate in the match, then `last`.
`m[n].second`	For all integers `0 < n < m.size()`, the end of the sequence that matched sub-expression `n`. Alternatively, if sub-expression `n` did not participate in the match, then `last` .
`m[n].matched`	For all integers `0 < n < m.size()`, `true` if sub-expression `n` participated in the match, `false` otherwise.

```
template <class charT, class Allocator, class traits>
bool regex_search(const charT* str, match_results<const charT*, Allocator>& m,
                  const basic_regex<charT, traits>& e,
                  regex_constants::match_flag_type flags =
                    regex_constants::match_default);
```

2 *Returns:* The result of `regex_search(str, str + char_traits<charT>::length(str), m, e, flags)`.

```
template <class ST, class SA, class Allocator, class charT, class traits>
  bool regex_search(const basic_string<charT, ST, SA>& s,
                    match_results<
                      typename basic_string<charT, ST, SA>::const_iterator,
                      Allocator>& m,
                    const basic_regex<charT, traits>& e,
                    regex_constants::match_flag_type flags =
                      regex_constants::match_default);
```

3 *Returns:* The result of `regex_search(s.begin(), s.end(), m, e, flags)`.

```
template <class BidirectionalIterator, class charT, class traits>
  bool regex_search(BidirectionalIterator first, BidirectionalIterator last,
                    const basic_regex<charT, traits>& e,
                    regex_constants::match_flag_type flags =
                      regex_constants::match_default);
```

1 *Effects:* Behaves "as if" by constructing an object `what` of type `match_results<BidirectionalIterator>` and then returning the result of `regex_search(first, last, what, e, flags)`.

```
template <class charT, class traits>
  bool regex_search(const charT* str,
                    const basic_regex<charT, traits>& e,
                    regex_constants::match_flag_type flags =
                      regex_constants::match_default);
```

2 *Returns:* `regex_search(str, str + char_traits<charT>::length(str), e, flags)`

```
template <class ST, class SA, class charT, class traits>
  bool regex_search(const basic_string<charT, ST, SA>& s,
                    const basic_regex<charT, traits>& e,
                    regex_constants::match_flag_type flags =
                      regex_constants::match_default);
```

3 *Returns:* `regex_search(s.begin(), s.end(), e, flags)`.

28.41.1 regex_replace [re.alg.replace]

```
template <class OutputIterator, class BidirectionalIterator,
    class traits, class charT, class ST, class SA>
  OutputIterator
  regex_replace(OutputIterator out,
                BidirectionalIterator first, BidirectionalIterator last,
                const basic_regex<charT, traits>& e,
                const basic_string<charT, ST, SA>& fmt,
                regex_constants::match_flag_type flags =
                  regex_constants::match_default);
template <class OutputIterator, class BidirectionalIterator,
    class traits, class charT>
  OutputIterator
  regex_replace(OutputIterator out,
                BidirectionalIterator first, BidirectionalIterator last,
                const basic_regex<charT, traits>& e,
                const charT* fmt,
                regex_constants::match_flag_type flags =
                  regex_constants::match_default);
```

1 *Effects:* Constructs a `regex_iterator` object `i` as if by

```
regex_iterator<BidirectionalIterator, charT, traits> i(first, last, e, flags)
```

and uses `i` to enumerate through all of the matches `m` of type `match_results<BidirectionalIterator>` that occur within the sequence `[first,last)`. If no such matches are found and `!(flags & regex_constants::format_no_copy)` then calls

```
out = std::copy(first, last, out)
```

If any matches are found then, for each such match:

(1.1) — If `!(flags & regex_constants::format_no_copy)`, calls

```
out = std::copy(m.prefix().first, m.prefix().second, out)
```

(1.2) — Then calls

```
out = m.format(out, fmt, flags)
```

for the first form of the function and

```
out = m.format(out, fmt, fmt + char_traits<charT>::length(fmt), flags)
```

for the second.

Finally, if such a match is found and `!(flags & regex_constants::format_no_copy)`, calls

```
out = std::copy(last_m.suffix().first, last_m.suffix().second, out)
```

where `last_m` is a copy of the last match found. If `flags & regex_constants::format_first_only` is non-zero then only the first match found is replaced.

2 *Returns:* `out`.

```
template <class traits, class charT, class ST, class SA, class FST, class FSA>
  basic_string<charT, ST, SA>
  regex_replace(const basic_string<charT, ST, SA>& s,
                const basic_regex<charT, traits>& e,
```

```
                const basic_string<charT, FST, FSA>& fmt,
                regex_constants::match_flag_type flags =
                  regex_constants::match_default);
template <class traits, class charT, class ST, class SA>
  basic_string<charT, ST, SA>
  regex_replace(const basic_string<charT, ST, SA>& s,
                const basic_regex<charT, traits>& e,
                const charT* fmt,
                regex_constants::match_flag_type flags =
                  regex_constants::match_default);
```

3 *Effects:* Constructs an empty string `result` of type `basic_string<charT, ST, SA>` and calls `regex_replace(back_inserter(result), s.begin(), s.end(), e, fmt, flags)`.

4 *Returns:* `result`.

```
template <class traits, class charT, class ST, class SA>
  basic_string<charT>
  regex_replace(const charT* s,
                const basic_regex<charT, traits>& e,
                const basic_string<charT, ST, SA>& fmt,
                regex_constants::match_flag_type flags =
                  regex_constants::match_default);
template <class traits, class charT>
  basic_string<charT>
  regex_replace(const charT* s,
                const basic_regex<charT, traits>& e,
                const charT* fmt,
                regex_constants::match_flag_type flags =
                  regex_constants::match_default);
```

5 *Effects:* Constructs an empty string `result` of type `basic_string<charT>` and calls `regex_replace(back_inserter(result), s, s + char_traits<charT>::length(s), e, fmt, flags)`.

6 *Returns:* `result`.

28.42 Regular expression iterators [re.iter]

28.42.1 Class template `regex_iterator` [re.regiter]

1

The class template `regex_iterator` is an iterator adaptor. It represents a new view of an existing iterator sequence, by enumerating all the occurrences of a regular expression within that sequence. A `regex_iterator` uses `regex_search` to find successive regular expression matches within the sequence from which it was constructed. After the iterator is constructed, and every time `operator++` is used, the iterator finds and stores a value of `match_results<BidirectionalIterator>`. If the end of the sequence is reached (`regex_search` returns `false`), the iterator becomes equal to the end-of-sequence iterator value. The default constructor constructs an end-of-sequence iterator object, which is the only legitimate iterator to be used for the end condition. The result of `operator*` on an end-of-sequence iterator is not defined. For any other iterator value a const `match_results<BidirectionalIterator>&` is returned. The result of `operator->` on an end-of-sequence iterator is not defined. For any other iterator value a `const match_results<BidirectionalIterator>*` is returned. It is impossible to store things into `regex_iterator`s. Two end-of-sequence iterators are always equal. An end-of-sequence iterator is not equal to a non-end-of-sequence iterator. Two non-end-of-sequence iterators are equal when they are constructed from the same arguments.

```
namespace std {
```

```
template <class BidirectionalIterator,
          class charT = typename iterator_traits<
            BidirectionalIterator>::value_type,
            class traits = regex_traits<charT> >
class regex_iterator {
public:
   typedef basic_regex<charT, traits>           regex_type;
   typedef match_results<BidirectionalIterator> value_type;
   typedef std::ptrdiff_t                       difference_type;
   typedef const value_type*                    pointer;
   typedef const value_type&                    reference;
   typedef std::forward_iterator_tag            iterator_category;

   regex_iterator();
   regex_iterator(BidirectionalIterator a, BidirectionalIterator b,
                  const regex_type& re,
                  regex_constants::match_flag_type m =
                    regex_constants::match_default);
   regex_iterator(BidirectionalIterator a, BidirectionalIterator b,
                  const regex_type&& re,
                  regex_constants::match_flag_type m =
                    regex_constants::match_default) = delete;
   regex_iterator(const regex_iterator&);
   regex_iterator& operator=(const regex_iterator&);
   bool operator==(const regex_iterator&) const;
   bool operator!=(const regex_iterator&) const;
   const value_type& operator*() const;
   const value_type* operator->() const;
   regex_iterator& operator++();
   regex_iterator operator++(int);
private:
   BidirectionalIterator                begin;  // exposition only
   BidirectionalIterator                end;    // exposition only
   const regex_type*                    pregex; // exposition only
   regex_constants::match_flag_type     flags;  // exposition only
   match_results<BidirectionalIterator> match;  // exposition only
};
}
```

1 An object of type `regex_iterator` that is not an end-of-sequence iterator holds a *zero-length match* if `match[0].matched == true` and `match[0].first == match[0].second`. [*Note:* For example, this can occur when the part of the regular expression that matched consists only of an assertion (such as `'^'`, `'$'`, `'\b'`, `'\B'`). — *end note*]

28.43.0.1 `regex_iterator` constructors [re.regiter.cnstr]

```
regex_iterator();
```

1 *Effects:* Constructs an end-of-sequence iterator.

```
regex_iterator(BidirectionalIterator a, BidirectionalIterator b,
               const regex_type& re,
               regex_constants::match_flag_type m = regex_constants::match_default);
```

2 *Effects:* Initializes `begin` and `end` to `a` and `b`, respectively, sets `pregex` to `&re`, sets `flags` to `m`, then calls `regex_search(begin, end, match, *pregex, flags)`. If this call returns `false` the constructor sets `*this` to the end-of-sequence iterator.

28.43.0.2 `regex_iterator` comparisons [re.regiter.comp]

`bool operator==(const regex_iterator& right) const;`

1 *Returns:* `true` if `*this` and `right` are both end-of-sequence iterators or if the following conditions all hold:

(1.1) — `begin == right.begin`,

(1.2) — `end == right.end`,

(1.3) — `pregex == right.pregex`,

(1.4) — `flags == right.flags`, and

(1.5) — `match[0] == right.match[0]`;

otherwise `false`.

`bool operator!=(const regex_iterator& right) const;`

2 *Returns:* `!(*this == right)`.

28.43.0.3 `regex_iterator` indirection [re.regiter.deref]

`const value_type& operator*() const;`

1 *Returns:* `match`.

`const value_type* operator->() const;`

2 *Returns:* `&match`.

28.43.0.4 `regex_iterator` increment [re.regiter.incr]

`regex_iterator& operator++();`

1 *Effects:* Constructs a local variable `start` of type `BidirectionalIterator` and initializes it with the value of `match[0].second`.

2 If the iterator holds a zero-length match and `start == end` the operator sets `*this` to the end-of-sequence iterator and returns `*this`.

3 Otherwise, if the iterator holds a zero-length match the operator calls `regex_search(start, end, match, *pregex, flags | regex_constants::match_not_null | regex_constants::match_continuous)`. If the call returns `true` the operator returns `*this`. Otherwise the operator increments `start` and continues as if the most recent match was not a zero-length match.

4 If the most recent match was not a zero-length match, the operator sets `flags` to `flags | regex_constants ::match_prev_avail` and calls `regex_search(start, end, match, *pregex, flags)`. If the call returns `false` the iterator sets `*this` to the end-of-sequence iterator. The iterator then returns `*this`.

5 In all cases in which the call to `regex_search` returns `true`, `match.prefix().first` shall be equal to the previous value of `match[0].second`, and for each index `i` in the half-open range `[0, match.size())` for which `match[i].matched` is true, `match[i].position()` shall return `distance(begin, match[i].first)`.

6 [*Note:* This means that `match[i].position()` gives the offset from the beginning of the target sequence, which is often not the same as the offset from the sequence passed in the call to `regex_search`. — *end note*]

7 It is unspecified how the implementation makes these adjustments.

8 [*Note:* This means that a compiler may call an implementation-specific search function, in which case a user-defined specialization of `regex_search` will not be called. — *end note*]

```
regex_iterator operator++(int);
```

9 *Effects:*

```
regex_iterator tmp = *this;
++(*this);
return tmp;
```

28.43.1 Class template `regex_token_iterator` [re.tokiter]

1 The class template `regex_token_iterator` is an iterator adaptor; that is to say it represents a new view of an existing iterator sequence, by enumerating all the occurrences of a regular expression within that sequence, and presenting one or more sub-expressions for each match found. Each position enumerated by the iterator is a `sub_match` class template instance that represents what matched a particular sub-expression within the regular expression.

2 When class `regex_token_iterator` is used to enumerate a single sub-expression with index -1 the iterator performs field splitting: that is to say it enumerates one sub-expression for each section of the character container sequence that does not match the regular expression specified.

3 After it is constructed, the iterator finds and stores a value `regex_iterator<BidirectionalIterator> position` and sets the internal count `N` to zero. It also maintains a sequence `subs` which contains a list of the sub-expressions which will be enumerated. Every time `operator++` is used the count `N` is incremented; if `N` exceeds or equals `subs.size()`, then the iterator increments member `position` and sets count `N` to zero.

4

If the end of sequence is reached (`position` is equal to the end of sequence iterator), the iterator becomes equal to the end-of-sequence iterator value, unless the sub-expression being enumerated has index -1, in which case the iterator enumerates one last sub-expression that contains all the characters from the end of the last regular expression match to the end of the input sequence being enumerated, provided that this would not be an empty sub-expression.

1 The default constructor constructs an end-of-sequence iterator object, which is the only legitimate iterator to be used for the end condition. The result of `operator*` on an end-of-sequence iterator is not defined. For any other iterator value a `const sub_match<BidirectionalIterator>&` is returned. The result of `operator->` on an end-of-sequence iterator is not defined. For any other iterator value a `const sub_match<BidirectionalIterator>*` is returned.

2 It is impossible to store things into `regex_token_iterators`. Two end-of-sequence iterators are always equal. An end-of-sequence iterator is not equal to a non-end-of-sequence iterator. Two non-end-of-sequence iterators are equal when they are constructed from the same arguments.

```
namespace std {
  template <class BidirectionalIterator,
            class charT = typename iterator_traits<
              BidirectionalIterator>::value_type,
              class traits = regex_traits<charT> >
  class regex_token_iterator  {
  public:
    typedef basic_regex<charT, traits>       regex_type;
    typedef sub_match<BidirectionalIterator> value_type;
    typedef std::ptrdiff_t                   difference_type;
    typedef const value_type*                pointer;
    typedef const value_type&                reference;
    typedef std::forward_iterator_tag        iterator_category;

    regex_token_iterator();
```

```
  regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                       const regex_type& re,
                       int submatch = 0,
                       regex_constants::match_flag_type m =
                         regex_constants::match_default);
  regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                       const regex_type& re,
                       const std::vector<int>& submatches,
                       regex_constants::match_flag_type m =
                         regex_constants::match_default);
  regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                       const regex_type& re,
                       initializer_list<int> submatches,
                       regex_constants::match_flag_type m =
                         regex_constants::match_default);
  template <std::size_t N>
    regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                       const regex_type& re,
                       const int (&submatches)[N],
                       regex_constants::match_flag_type m =
                         regex_constants::match_default);
  regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                        const regex_type&& re,
                        int submatch = 0,
                        regex_constants::match_flag_type m =
                          regex_constants::match_default) = delete;
  regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                        const regex_type&& re,
                        const std::vector<int>& submatches,
                        regex_constants::match_flag_type m =
                          regex_constants::match_default) = delete;
  regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                        const regex_type&& re,
                        initializer_list<int> submatches,
                        regex_constants::match_flag_type m =
                          regex_constants::match_default) = delete;
  template <std::size_t N>
  regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                        const regex_type&& re,
                        const int (&submatches)[N],
                        regex_constants::match_flag_type m =
                          regex_constants::match_default) = delete;
  regex_token_iterator(const regex_token_iterator&);
  regex_token_iterator& operator=(const regex_token_iterator&);
  bool operator==(const regex_token_iterator&) const;
  bool operator!=(const regex_token_iterator&) const;
  const value_type& operator*() const;
  const value_type* operator->() const;
  regex_token_iterator& operator++();
  regex_token_iterator operator++(int);
private:
  typedef
    regex_iterator<BidirectionalIterator, charT, traits> position_iterator; // exposition only
  position_iterator position;                                               // exposition only
  const value_type* result;                                                 // exposition only
```

```
    value_type suffix;                                    // exposition only
    std::size_t N;                                        // exposition only
    std::vector<int> subs;                                // exposition only
  };
}
```

3 A *suffix iterator* is a `regex_token_iterator` object that points to a final sequence of characters at the end of the target sequence. In a suffix iterator the member `result` holds a pointer to the data member `suffix`, the value of the member `suffix.match` is `true`, `suffix.first` points to the beginning of the final sequence, and `suffix.second` points to the end of the final sequence.

4 [*Note:* For a suffix iterator, data member `suffix.first` is the same as the end of the last match found, and `suffix.second` is the same as the end of the target sequence — *end note*]

5 The *current match* is `(*position).prefix()` if `subs[N] == -1`, or `(*position)[subs[N]]` for any other value of `subs[N]`.

28.44.0.1 `regex_token_iterator` constructors [re.tokiter.cnstr]

```
regex_token_iterator();
```

1 *Effects:* Constructs the end-of-sequence iterator.

```
regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                     const regex_type& re,
                     int submatch = 0,
                     regex_constants::match_flag_type m =
                      regex_constants::match_default);

regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                     const regex_type& re,
                     const std::vector<int>& submatches,
                     regex_constants::match_flag_type m =
                      regex_constants::match_default);

regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                     const regex_type& re,
                     initializer_list<int> submatches,
                     regex_constants::match_flag_type m =
                       regex_constants::match_default);

template <std::size_t N>
  regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                     const regex_type& re,
                     const int (&submatches)[N],
                     regex_constants::match_flag_type m =
                      regex_constants::match_default);
```

2 *Requires:* Each of the initialization values of `submatches` shall be `>= -1`.

3 *Effects:* The first constructor initializes the member `subs` to hold the single value `submatch`. The second constructor initializes the member `subs` to hold a copy of the argument `submatches`. The third and fourth constructors initialize the member `subs` to hold a copy of the sequence of integer values pointed to by the iterator range `[submatches.begin(),submatches.end())` and `[&submatches,&submatches + N)`, respectively.

4 Each constructor then sets `N` to 0, and `position` to `position_iterator(a, b, re, m)`. If `position` is not an end-of-sequence iterator the constructor sets `result` to the address of the current match.

Otherwise if any of the values stored in `subs` is equal to -1 the constructor sets `*this` to a suffix iterator that points to the range `[a,b)`, otherwise the constructor sets `*this` to an end-of-sequence iterator.

28.44.0.2 `regex_token_iterator` comparisons [re.tokiter.comp]

```
bool operator==(const regex_token_iterator& right) const;
```

1 *Returns:* `true` if `*this` and `right` are both end-of-sequence iterators, or if `*this` and `right` are both suffix iterators and `suffix == right.suffix`; otherwise returns `false` if `*this` or `right` is an end-of-sequence iterator or a suffix iterator. Otherwise returns `true` if `position == right.position`, `N == right.N`, and `subs == right.subs`. Otherwise returns `false`.

```
bool operator!=(const regex_token_iterator& right) const;
```

2 *Returns:* `!(*this == right)`.

28.44.0.3 `regex_token_iterator` indirection [re.tokiter.deref]

```
const value_type& operator*() const;
```

1 *Returns:* `*result`.

```
const value_type* operator->() const;
```

2 *Returns:* `result`.

28.44.0.4 `regex_token_iterator` increment [re.tokiter.incr]

```
regex_token_iterator& operator++();
```

1 *Effects:* Constructs a local variable `prev` of type `position_iterator`, initialized with the value of `position`.

2 If `*this` is a suffix iterator, sets `*this` to an end-of-sequence iterator.

3 Otherwise, if `N + 1 < subs.size()`, increments `N` and sets `result` to the address of the current match.

4 Otherwise, sets `N` to 0 and increments `position`. If `position` is not an end-of-sequence iterator the operator sets `result` to the address of the current match.

5 Otherwise, if any of the values stored in `subs` is equal to -1 and `prev->suffix().length()` is not 0 the operator sets `*this` to a suffix iterator that points to the range `[prev->suffix().first, prev->suffix().second)`.

6 Otherwise, sets `*this` to an end-of-sequence iterator.

Returns: `*this`

```
regex_token_iterator& operator++(int);
```

7 *Effects:* Constructs a copy `tmp` of `*this`, then calls `++(*this)`.

8 *Returns:* `tmp`.

28.45 Modified ECMAScript regular expression grammar [re.grammar]

1

The regular expression grammar recognized by `basic_regex` objects constructed with the ECMAScript flag is that specified by ECMA-262, except as specified below.

1 Objects of type specialization of `basic_regex` store within themselves a default-constructed instance of their `traits` template parameter, henceforth referred to as `traits_inst`. This `traits_inst` object is used

to support localization of the regular expression; `basic_regex` member functions shall not call any locale dependent C or C++ API, including the formatted string input functions. Instead they shall call the appropriate traits member function to achieve the required effect.

2 The following productions within the ECMAScript grammar are modified as follows:

```
ClassAtom ::
  -
  ClassAtomNoDash
  ClassAtomExClass
  ClassAtomCollatingElement
  ClassAtomEquivalence
```

3 The following new productions are then added:

```
ClassAtomExClass ::
  [: ClassName :]

ClassAtomCollatingElement ::
  [. ClassName .]

ClassAtomEquivalence ::
  [= ClassName =]

ClassName ::
  ClassNameCharacter
  ClassNameCharacter ClassName

ClassNameCharacter ::
  SourceCharacter but not one of "." "=" ":"
```

4 The productions `ClassAtomExClass`, `ClassAtomCollatingElement` and `ClassAtomEquivalence` provide functionality equivalent to that of the same features in regular expressions in POSIX.

5 The regular expression grammar may be modified by any `regex_constants::syntax_option_type` flags specified when constructing an object of type specialization of `basic_regex` according to the rules in Table 138.

6 A `ClassName` production, when used in `ClassAtomExClass`, is not valid if `traits_inst.lookup_classname` returns zero for that name. The names recognized as valid `ClassName`s are determined by the type of the traits class, but at least the following names shall be recognized: `alnum`, `alpha`, `blank`, `cntrl`, `digit`, `graph`, `lower`, `print`, `punct`, `space`, `upper`, `xdigit`, `d`, `s`, `w`. In addition the following expressions shall be equivalent:

```
\d and [[:digit:]]

\D and [^[:digit:]]

\s and [[:space:]]

\S and [^[:space:]]

\w and [_[:alnum:]]

\W and [^_[:alnum:]]
```

7 A `ClassName` production when used in a `ClassAtomCollatingElement` production is not valid if the value returned by `traits_inst.lookup_collatename` for that name is an empty string.

8 The results from multiple calls to `traits_inst.lookup_classname` can be bitwise OR'ed together and subsequently passed to `traits_inst.isctype`.

9 A `ClassName` production when used in a `ClassAtomEquivalence` production is not valid if the value returned by `traits_inst.lookup_collatename` for that name is an empty string or if the value returned by `traits_inst.transform_primary` for the result of the call to `traits_inst.lookup_collatename` is an empty string.

10 When the sequence of characters being transformed to a finite state machine contains an invalid class name the translator shall throw an exception object of type `regex_error`.

11 If the *CV* of a *UnicodeEscapeSequence* is greater than the largest value that can be held in an object of type `charT` the translator shall throw an exception object of type `regex_error`. [*Note:* This means that values of the form `"uxxxx"` that do not fit in a character are invalid. — *end note*]

12 Where the regular expression grammar requires the conversion of a sequence of characters to an integral value, this is accomplished by calling `traits_inst.value`.

13

The behavior of the internal finite state machine representation when used to match a sequence of characters is as described in ECMA-262. The behavior is modified according to any match_flag_type flags 28.10.1 specified when using the regular expression object in one of the regular expression algorithms 28.33. The behavior is also localized by interaction with the traits class template parameter as follows:

— During matching of a regular expression finite state machine against a sequence of characters, two characters `c` and `d` are compared using the following rules:

1. if `(flags() & regex_constants::icase)` the two characters are equal if `traits_inst.translate_nocase(c) == traits_inst.translate_nocase(d)`;
2. otherwise, if `flags() & regex_constants::collate` the two characters are equal if `traits_inst.translate(c) == traits_inst.translate(d)`;
3. otherwise, the two characters are equal if `c == d`.

— During matching of a regular expression finite state machine against a sequence of characters, comparison of a collating element range `c1-c2` against a character `c` is conducted as follows: if `flags() & regex_constants ::collate` is false then the character `c` is matched if `c1 <= c && c <= c2`, otherwise `c` is matched in accordance with the following algorithm:

```
string_type str1 = string_type(1,
  flags() & icase ?
    traits_inst.translate_nocase(c1) : traits_inst.translate(c1);
string_type str2 = string_type(1,
  flags() & icase ?
    traits_inst.translate_nocase(c2) : traits_inst.translate(c2);
string_type str = string_type(1,
  flags() & icase ?
    traits_inst.translate_nocase(c) : traits_inst.translate(c);
return traits_inst.transform(str1.begin(), str1.end())
      <= traits_inst.transform(str.begin(), str.end())
  && traits_inst.transform(str.begin(), str.end())
      <= traits_inst.transform(str2.begin(), str2.end());
```

— During matching of a regular expression finite state machine against a sequence of characters, testing whether a collating element is a member of a primary equivalence class is conducted by first converting the collating element and the equivalence class to sort keys using `traits::transform_primary`, and then comparing the sort keys for equality.

— During matching of a regular expression finite state machine against a sequence of characters, a character `c` is a member of a character class designated by an iterator range `[first,last)` if `traits_inst.isctype(c, traits_inst.lookup_classname(first, last, flags() & icase))` is `true`.

29 Atomic operations library [atomics]

29.1 General [atomics.general]

1 This Clause describes components for fine-grained atomic access. This access is provided via operations on atomic objects.

2 The following subclauses describe atomics requirements and components for types and operations, as summarized below.

Table 145 — Atomics library summary

Subclause		Header(s)
29.3	Order and Consistency	
29.31	Lock-free Property	
29.32	Atomic Types	`<atomic>`
29.50	Operations on Atomic Types	
29.77	Flag Type and Operations	
29.85	Fences	

29.2 Header `<atomic>` synopsis [atomics.syn]

```
namespace std {

  // 29.85, fences
  extern "C" void atomic_thread_fence(memory_order) noexcept;
  extern "C" void atomic_signal_fence(memory_order) noexcept;
}
```

29.3 Order and consistency [atomics.order]

```
namespace std {
  typedef enum memory_order {
    memory_order_relaxed, memory_order_consume, memory_order_acquire,
    memory_order_release, memory_order_acq_rel, memory_order_seq_cst
  } memory_order;
}
```

1

The enumeration `memory_order` specifies the detailed regular (non-atomic) memory synchronization order as defined in 1.859 and may provide for operation ordering. Its enumerated values and their meanings are as follows:

— `memory_order_relaxed`: no operation orders memory.

— `memory_order_release`, `memory_order_acq_rel`, and `memory_order_seq_cst`: a store operation performs a release operation on the affected memory location.

— `memory_order_consume`: a load operation performs a consume operation on the affected memory location.

— `memory_order_acquire`, `memory_order_acq_rel`, and `memory_order_seq_cst`: a load operation performs an acquire operation on the affected memory location.

[*Note:* Atomic operations specifying `memory_order_relaxed` are relaxed with respect to memory ordering. Implementations must still guarantee that any given atomic access to a particular atomic object be indivisible with respect to all other atomic accesses to that object. — *end note*]

1

An atomic operation A that performs a release operation on an atomic object M synchronizes with an atomic operation B that performs an acquire operation on M and takes its value from any side effect in the release sequence headed by A.

1

There shall be a single total order S on all `memory_order_seq_cst` operations, consistent with the "happens before" order and modification orders for all affected locations, such that each `memory_order_seq_cst` operation B that loads a value from an atomic object M observes one of the following values:

— the result of the last modification A of M that precedes B in S, if it exists, or

— if A exists, the result of some modification of M that is not `memory_order_seq_cst` and that does not happen before A, or

— if A does not exist, the result of some modification of M that is not `memory_order_seq_cst`.

[*Note:* Although it is not explicitly required that S include locks, it can always be extended to an order that does include lock and unlock operations, since the ordering between those is already included in the "happens before" ordering. — *end note*]

1

For an atomic operation B that reads the value of an atomic object M, if there is a `memory_order_seq_cst` fence X sequenced before B, then B observes either the last `memory_order_seq_cst` modification of M preceding X in the total order S or a later modification of M in its modification order.

1 For atomic operations A and B on an atomic object M, where A modifies M and B takes its value, if there is a `memory_order_seq_cst` fence X such that A is sequenced before X and B follows X in S, then B observes either the effects of A or a later modification of M in its modification order.

2

For atomic operations A and B on an atomic object M, where A modifies M and B takes its value, if there are `memory_order_seq_cst` fences X and Y such that A is sequenced before X, Y is sequenced before B, and X precedes Y in S, then B observes either the effects of A or a later modification of M in its modification order.

1 For atomic modifications A and B of an atomic object M, B occurs later than A in the modification order of M if:

(1.1) — there is a `memory_order_seq_cst` fence X such that A is sequenced before X, and X precedes B in S, or

(1.2) — there is a `memory_order_seq_cst` fence Y such that Y is sequenced before B, and A precedes Y in S, or

(1.3) — there are `memory_order_seq_cst` fences X and Y such that A is sequenced before X, Y is sequenced before B, and X precedes Y in S.

2

[*Note:* `memory_order_seq_cst` ensures sequential consistency only for a program that is free of data races and uses exclusively `memory_order_seq_cst` operations. Any use of weaker ordering will invalidate this guarantee unless extreme care is used. In particular, `memory_order_seq_cst` fences ensure a total order only for the fences themselves. Fences cannot, in general, be used to restore sequential consistency for atomic operations with weaker ordering specifications. — *end note*]

1 Implementations should ensure that no "out-of-thin-air" values are computed that circularly depend on their own computation.

[*Note:* For example, with `x` and `y` initially zero,

```
// Thread 1:
r1 = y.load(memory_order_relaxed);
x.store(r1, memory_order_relaxed);

// Thread 2:
r2 = x.load(memory_order_relaxed);
y.store(r2, memory_order_relaxed);
```

should not produce `r1 == r2 == 42`, since the store of 42 to `y` is only possible if the store to `x` stores `42`, which circularly depends on the store to `y` storing `42`. Note that without this restriction, such an execution is possible. — *end note*]

2 [*Note:* The recommendation similarly disallows `r1 == r2 == 42` in the following example, with `x` and `y` again initially zero:

```
// Thread 1:
r1 = x.load(memory_order_relaxed);
if (r1 == 42) y.store(42, memory_order_relaxed);

// Thread 2:
r2 = y.load(memory_order_relaxed);
if (r2 == 42) x.store(42, memory_order_relaxed);
```

— *end note*]

3

Atomic read-modify-write operations shall always read the last value (in the modification order) written before the write associated with the read-modify-write operation.

1

Implementations should make atomic stores visible to atomic loads within a reasonable amount of time.

```
template <class T>
  T kill_dependency(T y) noexcept;
```

1 *Effects:* The argument does not carry a dependency to the return value (1.859).

2 *Returns:* `y`.

29.31 Lock-free property [atomics.lockfree]

```
#define ATOMIC_BOOL_LOCK_FREE unspecified
#define ATOMIC_CHAR_LOCK_FREE unspecified
#define ATOMIC_CHAR16_T_LOCK_FREE unspecified
#define ATOMIC_CHAR32_T_LOCK_FREE unspecified
#define ATOMIC_WCHAR_T_LOCK_FREE unspecified
#define ATOMIC_SHORT_LOCK_FREE unspecified
#define ATOMIC_INT_LOCK_FREE unspecified
#define ATOMIC_LONG_LOCK_FREE unspecified
#define ATOMIC_LLONG_LOCK_FREE unspecified
#define ATOMIC_POINTER_LOCK_FREE unspecified
```

1 The `ATOMIC_..._LOCK_FREE` macros indicate the lock-free property of the corresponding atomic types, with the signed and unsigned variants grouped together. The properties also apply to the corresponding (partial) specializations of the `atomic` template. A value of 0 indicates that the types are never lock-free. A value of 1 indicates that the types are sometimes lock-free. A value of 2 indicates that the types are always lock-free.

2 The function `atomic_is_lock_free` (29.50) indicates whether the object is lock-free. In any given program execution, the result of the lock-free query shall be consistent for all pointers of the same type.

3 [*Note:* Operations that are lock-free should also be address-free. That is, atomic operations on the same memory location via two different addresses will communicate atomically. The implementation should not depend on any per-process state. This restriction enables communication by memory that is mapped into a process more than once and by memory that is shared between two processes. — *end note*]

29.32 Atomic types [atomics.types.generic]

```
namespace std {
  template <class T> struct atomic {
    bool is_lock_free() const volatile noexcept;
    bool is_lock_free() const noexcept;
    void store(T, memory_order = memory_order_seq_cst) volatile noexcept;
    void store(T, memory_order = memory_order_seq_cst) noexcept;
    T load(memory_order = memory_order_seq_cst) const volatile noexcept;
    T load(memory_order = memory_order_seq_cst) const noexcept;
    operator T() const volatile noexcept;
    operator T() const noexcept;
    T exchange(T, memory_order = memory_order_seq_cst) volatile noexcept;
    T exchange(T, memory_order = memory_order_seq_cst) noexcept;
    bool compare_exchange_weak(T&, T, memory_order, memory_order) volatile noexcept;
    bool compare_exchange_weak(T&, T, memory_order, memory_order) noexcept;
    bool compare_exchange_strong(T&, T, memory_order, memory_order) volatile noexcept;
    bool compare_exchange_strong(T&, T, memory_order, memory_order) noexcept;
    bool compare_exchange_weak(T&, T, memory_order = memory_order_seq_cst) volatile noexcept;
    bool compare_exchange_weak(T&, T, memory_order = memory_order_seq_cst) noexcept;
    bool compare_exchange_strong(T&, T, memory_order = memory_order_seq_cst) volatile noexcept;
    bool compare_exchange_strong(T&, T, memory_order = memory_order_seq_cst) noexcept;

    atomic() noexcept = default;
    constexpr atomic(T) noexcept;
    atomic(const atomic&) = delete;
    atomic& operator=(const atomic&) = delete;
    atomic& operator=(const atomic&) volatile = delete;
    T operator=(T) volatile noexcept;
    T operator=(T) noexcept;
  };

  template <> struct atomic<integral> {
    bool is_lock_free() const volatile noexcept;
    bool is_lock_free() const noexcept;

}
```

1

There is a generic class template `atomic<T>`. The type of the template argument `T` shall be trivially copyable (3.2955). [*Note:* Type arguments that are not also statically initializable may be difficult to use. — *end note*]

1

The semantics of the operations on specializations of `atomic` are defined in 29.50.

1 Specializations and instantiations of the `atomic` template shall have a deleted copy constructor, a deleted copy assignment operator, and a constexpr value constructor.

2

There shall be explicit specializations of the `atomic` template for the integral types `char`, `signed char`, `unsigned char`, `short`, `unsigned short`, `int`, `unsigned int`, `long`, `unsigned long`, `long long`, `unsigned long long`, `char16_t`, `char32_t`, `wchar_t`, and any other types needed by the typedefs in the header `<cstdint>`. For each integral type *integral*, the specialization `atomic<integral>` provides additional atomic operations appropriate to integral types. There shall be a specialization `atomic<bool>` which provides the general atomic operations as specified in 29.50.1.

1

The atomic integral specializations and the specialization `atomic<bool>` shall have standard layout. They

shall each have a trivial default constructor and a trivial destructor. They shall each support aggregate initialization syntax.

1

There shall be pointer partial specializations of the `atomic` class template. These specializations shall have standard layout, trivial default constructors, and trivial destructors. They shall each support aggregate initialization syntax.

1

There shall be named types corresponding to the integral specializations of `atomic`, as specified in Table 146, and a named type `atomic_bool` corresponding to the specified `atomic<bool>`. Each named type is either a typedef to the corresponding specialization or a base class of the corresponding specialization. If it is a base class, it shall support the same member functions as the corresponding specialization.

Table 146 — `atomic` integral typedefs

Named type	Integral argument type
`atomic_char`	`char`
`atomic_schar`	`signed char`
`atomic_uchar`	`unsigned char`
`atomic_short`	`short`
`atomic_ushort`	`unsigned short`
`atomic_int`	`int`
`atomic_uint`	`unsigned int`
`atomic_long`	`long`
`atomic_ulong`	`unsigned long`
`atomic_llong`	`long long`
`atomic_ullong`	`unsigned long long`
`atomic_char16_t`	`char16_t`
`atomic_char32_t`	`char32_t`
`atomic_wchar_t`	`wchar_t`

1 There shall be atomic typedefs corresponding to the typedefs in the header `<inttypes.h>` as specified in Table 147.

2

[*Note:* The representation of an atomic specialization need not have the same size as its corresponding argument type. Specializations should have the same size whenever possible, as this reduces the effort required to port existing code. — *end note*]

29.50 Operations on atomic types [atomics.types.operations]

29.50.1 General operations on atomic types [atomics.types.operations.general]

1 The implementation shall provide the functions and function templates identified as "general operations on atomic types" in 29.2.

2 In the declarations of these functions and function templates, the name *atomic-type* refers to either `atomic<T>` or to a named base class for `T` from Table 146 or inferred from Table 147.

29.50.2 Templated operations on atomic types [atomics.types.operations.templ]

1 The implementation shall declare but not define the function templates identified as "templated operations on atomic types" in 29.2.

Table 147 — `atomic <inttypes.h>` typedefs

Atomic typedef	<inttypes.h> type
atomic_int_least8_t	int_least8_t
atomic_uint_least8_t	uint_least8_t
atomic_int_least16_t	int_least16_t
atomic_uint_least16_t	uint_least16_t
atomic_int_least32_t	int_least32_t
atomic_uint_least32_t	uint_least32_t
atomic_int_least64_t	int_least64_t
atomic_uint_least64_t	uint_least64_t
atomic_int_fast8_t	int_fast8_t
atomic_uint_fast8_t	uint_fast8_t
atomic_int_fast16_t	int_fast16_t
atomic_uint_fast16_t	uint_fast16_t
atomic_int_fast32_t	int_fast32_t
atomic_uint_fast32_t	uint_fast32_t
atomic_int_fast64_t	int_fast64_t
atomic_uint_fast64_t	uint_fast64_t
atomic_intptr_t	intptr_t
atomic_uintptr_t	uintptr_t
atomic_size_t	size_t
atomic_ptrdiff_t	ptrdiff_t
atomic_intmax_t	intmax_t
atomic_uintmax_t	uintmax_t

29.50.3 Arithmetic operations on atomic types [atomics.types.operations.arith]

1 The implementation shall provide the functions and function template specializations identified as "arithmetic operations on atomic types" in 29.2.

2

In the declarations of these functions and function template specializations, the name *integral* refers to an integral type and the name *atomic-integral* refers to either `atomic<`*`integral`*`>` or to a named base class for *`integral`* from Table 146 or inferred from Table 147.

29.51.1 Operations on atomic pointer types [atomics.types.operations.pointer]

1 The implementation shall provide the function template specializations identified as "partial specializations for pointers" in 29.2.

29.51.2 Requirements for operations on atomic types [atomics.types.operations.req]

1 There are only a few kinds of operations on atomic types, though there are many instances on those kinds. This section specifies each general kind. The specific instances are defined in 29.32, 29.50.1, 29.50.3, and 29.51.1.

2

In the following operation definitions:

— an A refers to one of the atomic types.

— a C refers to its corresponding non-atomic type.

— an *M* refers to type of the other argument for arithmetic operations. For integral atomic types, *M* is *C*. For atomic address types, *M* is `std::ptrdiff_t`.

— the non-member functions not ending in `_explicit` have the semantics of their corresponding `_explicit` functions with `memory_order` arguments of `memory_order_seq_cst`.

1

[*Note:* Many operations are volatile-qualified. The "volatile as device register" semantics have not changed in the standard. This qualification means that volatility is preserved when applying these operations to volatile objects. It does not mean that operations on non-volatile objects become volatile. Thus, volatile qualified operations on non-volatile objects may be merged under some conditions. — *end note*]

```
A::A() noexcept = default;
```

1

Effects: leaves the atomic object in an uninitialized state. [*Note:* These semantics ensure compatibility with C. — *end note*]

```
constexpr A::A(C desired) noexcept;
```

1 *Effects:* Initializes the object with the value `desired`. Initialization is not an atomic operation (1.859). [*Note:* it is possible to have an access to an atomic object `A` race with its construction, for example by communicating the address of the just-constructed object `A` to another thread via `memory_order_relaxed` operations on a suitable atomic pointer variable, and then immediately accessing `A` in the receiving thread. This results in undefined behavior. — *end note*]

```
#define ATOMIC_VAR_INIT(value) see below
```

2

The macro expands to a token sequence suitable for constant initialization of an atomic variable of static storage duration of a type that is initialization-compatible with *value*. [*Note:* This operation may need to initialize locks. — *end note*] Concurrent access to the variable being initialized, even via an atomic operation, constitutes a data race. [*Example:*

```
atomic<int> v = ATOMIC_VAR_INIT(5);
```

— *end example*]

```
bool atomic_is_lock_free(const volatile A* object) noexcept;
bool atomic_is_lock_free(const A* object) noexcept;
bool A::is_lock_free() const volatile noexcept;
bool A::is_lock_free() const noexcept;
```

1

Returns: True if the object's operations are lock-free, false otherwise.

```
void atomic_init(volatile A* object, C desired) noexcept;
void atomic_init(A* object, C desired) noexcept;
```

1 *Effects:* Non-atomically initializes `*object` with value `desired`. This function shall only be applied to objects that have been default constructed, and then only once. [*Note:* These semantics ensure compatibility with C. — *end note*] [*Note:* Concurrent access from another thread, even via an atomic operation, constitutes a data race. — *end note*]

```
void atomic_store(volatile A* object, C desired) noexcept;
void atomic_store(A* object, C desired) noexcept;
void atomic_store_explicit(volatile A* object, C desired, memory_order order) noexcept;
void atomic_store_explicit(A* object, C desired, memory_order order) noexcept;
void A::store(C desired, memory_order order = memory_order_seq_cst) volatile noexcept;
void A::store(C desired, memory_order order = memory_order_seq_cst) noexcept;
```

2

Requires: The `order` argument shall not be `memory_order_consume`, `memory_order_acquire`, nor `memory_order_acq_rel`.

1

Effects: Atomically replaces the value pointed to by `object` or by `this` with the value of `desired`. Memory is affected according to the value of `order`.

```
C A::operator=(C desired) volatile noexcept;
C A::operator=(C desired) noexcept;
```

1 *Effects:* `store(desired)`

2 *Returns:* `desired`

```
C atomic_load(const volatile A* object) noexcept;
C atomic_load(const A* object) noexcept;
C atomic_load_explicit(const volatile A* object, memory_order) noexcept;
C atomic_load_explicit(const A* object, memory_order) noexcept;
C A::load(memory_order order = memory_order_seq_cst) const volatile noexcept;
C A::load(memory_order order = memory_order_seq_cst) const noexcept;
```

3

Requires: The `order` argument shall not be `memory_order_release` nor `memory_order_acq_rel`.

1 *Effects:* Memory is affected according to the value of `order`.

2 *Returns:* Atomically returns the value pointed to by `object` or by `this`.

```
A::operator C() const volatile noexcept;
A::operator C() const noexcept;
```

3 *Effects:* `load()`

4 *Returns:* The result of `load()`.

```
C atomic_exchange(volatile A* object, C desired) noexcept;
C atomic_exchange(A* object, C desired) noexcept;
C atomic_exchange_explicit(volatile A* object, C desired, memory_order) noexcept;
C atomic_exchange_explicit(A* object, C desired, memory_order) noexcept;
C A::exchange(C desired, memory_order order = memory_order_seq_cst) volatile noexcept;
C A::exchange(C desired, memory_order order = memory_order_seq_cst) noexcept;
```

5 *Effects:* Atomically replaces the value pointed to by `object` or by `this` with `desired`. Memory is affected according to the value of `order`. These operations are atomic read-modify-write operations (1.859).

6 *Returns:* Atomically returns the value pointed to by `object` or by `this` immediately before the effects.

```
bool atomic_compare_exchange_weak(volatile A* object, C* expected, C desired) noexcept;
bool atomic_compare_exchange_weak(A* object, C* expected, C desired) noexcept;
bool atomic_compare_exchange_strong(volatile A* object, C* expected, C desired) noexcept;
bool atomic_compare_exchange_strong(A* object, C* expected, C desired) noexcept;
bool atomic_compare_exchange_weak_explicit(volatile A* object, C* expected, C desired,
    memory_order success, memory_order failure) noexcept;
bool atomic_compare_exchange_weak_explicit(A* object, C* expected, C desired,
    memory_order success, memory_order failure) noexcept;
bool atomic_compare_exchange_strong_explicit(volatile A* object, C* expected, C desired,
    memory_order success, memory_order failure) noexcept;
bool atomic_compare_exchange_strong_explicit(A* object, C* expected, C desired,
    memory_order success, memory_order failure) noexcept;
bool A::compare_exchange_weak(C& expected, C desired,
    memory_order success, memory_order failure) volatile noexcept;
bool A::compare_exchange_weak(C& expected, C desired,
    memory_order success, memory_order failure) noexcept;
bool A::compare_exchange_strong(C& expected, C desired,
    memory_order success, memory_order failure) volatile noexcept;
bool A::compare_exchange_strong(C& expected, C desired,
    memory_order success, memory_order failure) noexcept;
bool A::compare_exchange_weak(C& expected, C desired,
    memory_order order = memory_order_seq_cst) volatile noexcept;
bool A::compare_exchange_weak(C& expected, C desired,
    memory_order order = memory_order_seq_cst) noexcept;
bool A::compare_exchange_strong(C& expected, C desired,
    memory_order order = memory_order_seq_cst) volatile noexcept;
bool A::compare_exchange_strong(C& expected, C desired,
    memory_order order = memory_order_seq_cst) noexcept;
```

7 *Requires:* The `failure` argument shall not be `memory_order_release` nor `memory_order_acq_rel`. The `failure` argument shall be no stronger than the `success` argument.

8

Effects: Atomically, compares the contents of the memory pointed to by `object` or by `this` for equality with that in `expected`, and if true, replaces the contents of the memory pointed to by `object` or by `this` with that in `desired`, and if false, updates the contents of the memory in `expected` with the contents of the memory pointed to by `object` or by `this`. Further, if the comparison is true, memory is affected according to the value of `success`, and if the comparison is false, memory is affected according to the value of `failure`. When only one `memory_order` argument is supplied, the value of `success` is `order`, and the value of `failure` is `order` except that a value of `memory_order_acq_rel` shall be replaced by the value `memory_order_acquire` and a value of `memory_order_release` shall be replaced by the value `memory_order_relaxed`. If the operation returns `true`, these operations are atomic read-modify-write operations (1.859). Otherwise, these operations are atomic load operations.

1 *Returns:* The result of the comparison.

2 [*Note:* For example, the effect of `atomic_compare_exchange_strong` is

```
if (memcmp(object, expected, sizeof(*object)) == 0)
  memcpy(object, &desired, sizeof(*object));
else
  memcpy(expected, object, sizeof(*object));
```

— *end note*] [*Example:* the expected use of the compare-and-exchange operations is as follows. The compare-and-exchange operations will update `expected` when another iteration of the loop is needed.

```
expected = current.load();
do {
  desired = function(expected);
} while (!current.compare_exchange_weak(expected, desired));
```

— *end example*]

3 Implementations should ensure that weak compare-and-exchange operations do not consistently return `false` unless either the atomic object has value different from `expected` or there are concurrent modifications to the atomic object.

1 *Remark:* A weak compare-and-exchange operation may fail spuriously. That is, even when the contents of memory referred to by `expected` and `object` are equal, it may return false and store back to `expected` the same memory contents that were originally there. [*Note:* This spurious failure enables implementation of compare-and-exchange on a broader class of machines, e.g., load-locked store-conditional machines. A consequence of spurious failure is that nearly all uses of weak compare-and-exchange will be in a loop.

When a compare-and-exchange is in a loop, the weak version will yield better performance on some platforms. When a weak compare-and-exchange would require a loop and a strong one would not, the strong one is preferable. — *end note*]

1 [*Note:* The `memcpy` and `memcmp` semantics of the compare-and-exchange operations may result in failed comparisons for values that compare equal with `operator==` if the underlying type has padding bits, trap bits, or alternate representations of the same value. Thus, `compare_exchange_strong` should be used with extreme care. On the other hand, `compare_exchange_weak` should converge rapidly. — *end note*]

1 The following operations perform arithmetic computations. The key, operator, and computation correspondence is:

Table 148 — Atomic arithmetic computations

Key	Op	Computation	Key	Op	Computation
`add`	`+`	addition	`sub`	`-`	subtraction
`or`	`|`	bitwise inclusive or	`xor`	`^`	bitwise exclusive or
`and`	`&`	bitwise and			

```
C atomic_fetch_key(volatile A* object, M operand) noexcept;
C atomic_fetch_key(A* object, M operand) noexcept;
C atomic_fetch_key_explicit(volatile A* object, M operand, memory_order order) noexcept;
C atomic_fetch_key_explicit(A* object, M operand, memory_order order) noexcept;
C A::fetch_key(M operand, memory_order order = memory_order_seq_cst) volatile noexcept;
C A::fetch_key(M operand, memory_order order = memory_order_seq_cst) noexcept;
```

2 *Effects:* Atomically replaces the value pointed to by `object` or by `this` with the result of the *computation* applied to the value pointed to by `object` or by `this` and the given `operand`. Memory is affected according to the value of `order`. These operations are atomic read-modify-write operations (1.859).

3 *Returns:* Atomically, the value pointed to by `object` or by `this` immediately before the effects.

4 *Remark:* For signed integer types, arithmetic is defined to use two's complement representation. There are no undefined results. For address types, the result may be an undefined address, but the operations otherwise have no undefined behavior.

```
C A::operator op=(M operand) volatile noexcept;
C A::operator op=(M operand) noexcept;
```

5 *Effects:* fetch_*key*(operand)

6 *Returns:* fetch_*key*(operand) op operand

```
C A::operator++(int) volatile noexcept;
C A::operator++(int) noexcept;
```

7 *Returns:* fetch_add(1)

```
C A::operator--(int) volatile noexcept;
C A::operator--(int) noexcept;
```

8 *Returns:* fetch_sub(1)

```
C A::operator++() volatile noexcept;
C A::operator++() noexcept;
```

9 *Effects:* fetch_add(1)

10 *Returns:* fetch_add(1) + 1

```
C A::operator--() volatile noexcept;
C A::operator--() noexcept;
```

11 *Effects:* fetch_sub(1)

12 *Returns:* fetch_sub(1) - 1

29.77 Flag type and operations [atomics.flag]

```
namespace std {
  typedef struct atomic_flag {
    bool test_and_set(memory_order = memory_order_seq_cst) volatile noexcept;
    bool test_and_set(memory_order = memory_order_seq_cst) noexcept;
    void clear(memory_order = memory_order_seq_cst) volatile noexcept;
    void clear(memory_order = memory_order_seq_cst) noexcept;

    atomic_flag() noexcept = default;
    atomic_flag(const atomic_flag&) = delete;
    atomic_flag& operator=(const atomic_flag&) = delete;
    atomic_flag& operator=(const atomic_flag&) volatile = delete;
  } atomic_flag;

  bool atomic_flag_test_and_set(volatile atomic_flag*) noexcept;
  bool atomic_flag_test_and_set(atomic_flag*) noexcept;
  bool atomic_flag_test_and_set_explicit(volatile atomic_flag*, memory_order) noexcept;
  bool atomic_flag_test_and_set_explicit(atomic_flag*, memory_order) noexcept;
  void atomic_flag_clear(volatile atomic_flag*) noexcept;
  void atomic_flag_clear(atomic_flag*) noexcept;
  void atomic_flag_clear_explicit(volatile atomic_flag*, memory_order) noexcept;
  void atomic_flag_clear_explicit(atomic_flag*, memory_order) noexcept;

  #define ATOMIC_FLAG_INIT see below
}
```

1 The `atomic_flag` type provides the classic test-and-set functionality. It has two states, set and clear.

2 Operations on an object of type `atomic_flag` shall be lock-free. [*Note:* Hence the operations should also be address-free. No other type requires lock-free operations, so the `atomic_flag` type is the minimum hardware-implemented type needed to conform to this International standard. The remaining types can be emulated with `atomic_flag`, though with less than ideal properties. — *end note*]

1 The `atomic_flag` type shall have standard layout. It shall have a trivial default constructor, a deleted copy constructor, a deleted copy assignment operator, and a trivial destructor.

2 The macro `ATOMIC_FLAG_INIT` shall be defined in such a way that it can be used to initialize an object of type `atomic_flag` to the clear state. The macro can be used in the form:

```
atomic_flag guard = ATOMIC_FLAG_INIT;
```

It is unspecified whether the macro can be used in other initialization contexts. For a complete static-duration object, that initialization shall be static. Unless initialized with `ATOMIC_FLAG_INIT`, it is unspecified whether an `atomic_flag` object has an initial state of set or clear.

```
bool atomic_flag_test_and_set(volatile atomic_flag* object) noexcept;
bool atomic_flag_test_and_set(atomic_flag* object) noexcept;
bool atomic_flag_test_and_set_explicit(volatile atomic_flag* object, memory_order order) noexcept;
bool atomic_flag_test_and_set_explicit(atomic_flag* object, memory_order order) noexcept;
bool atomic_flag::test_and_set(memory_order order = memory_order_seq_cst) volatile noexcept;
bool atomic_flag::test_and_set(memory_order order = memory_order_seq_cst) noexcept;
```

1

Effects: Atomically sets the value pointed to by `object` or by `this` to true. Memory is affected according to the value of `order`. These operations are atomic read-modify-write operations (1.859).

1 *Returns:* Atomically, the value of the object immediately before the effects.

```
void atomic_flag_clear(volatile atomic_flag* object) noexcept;
void atomic_flag_clear(atomic_flag* object) noexcept;
void atomic_flag_clear_explicit(volatile atomic_flag* object, memory_order order) noexcept;
void atomic_flag_clear_explicit(atomic_flag* object, memory_order order) noexcept;
void atomic_flag::clear(memory_order order = memory_order_seq_cst) volatile noexcept;
void atomic_flag::clear(memory_order order = memory_order_seq_cst) noexcept;
```

2 *Requires:* The `order` argument shall not be `memory_order_consume`, `memory_order_acquire`, nor `memory_order_acq_rel`.

3 *Effects:* Atomically sets the value pointed to by `object` or by `this` to false. Memory is affected according to the value of `order`.

29.85 Fences [atomics.fences]

1 This section introduces synchronization primitives called *fences*. Fences can have acquire semantics, release semantics, or both. A fence with acquire semantics is called an *acquire fence*. A fence with release semantics is called a *release fence*.

1 A release fence A synchronizes with an acquire fence B if there exist atomic operations X and Y, both operating on some atomic object M, such that A is sequenced before X, X modifies M, Y is sequenced before

B, and Y reads the value written by X or a value written by any side effect in the hypothetical release sequence X would head if it were a release operation.

1

A release fence A synchronizes with an atomic operation B that performs an acquire operation on an atomic object M if there exists an atomic operation X such that A is sequenced before X, X modifies M, and B reads the value written by X or a value written by any side effect in the hypothetical release sequence X would head if it were a release operation.

1 An atomic operation A that is a release operation on an atomic object M synchronizes with an acquire fence B if there exists some atomic operation X on M such that X is sequenced before B and reads the value written by A or a value written by any side effect in the release sequence headed by A.

```
extern "C" void atomic_thread_fence(memory_order order) noexcept;
```

2 *Effects:* depending on the value of `order`, this operation:

(2.1) — has no effects, if `order == memory_order_relaxed`;

(2.2) — is an acquire fence, if `order == memory_order_acquire || order == memory_order_consume`;

(2.3) — is a release fence, if `order == memory_order_release`;

(2.4) — is both an acquire fence and a release fence, if `order == memory_order_acq_rel`;

(2.5) — is a sequentially consistent acquire and release fence, if `order == memory_order_seq_cst`.

```
extern "C" void atomic_signal_fence(memory_order order) noexcept;
```

3 *Effects:* Equivalent to `atomic_thread_fence(order)`, except that the resulting ordering constraints are established only between a thread and a signal handler executed in the same thread.

4 *Note:* `atomic_signal_fence` can be used to specify the order in which actions performed by the thread become visible to the signal handler.

5 *Note:* compiler optimizations and reorderings of loads and stores are inhibited in the same way as with `atomic_thread_fence`, but the hardware fence instructions that `atomic_thread_fence` would have inserted are not emitted.

30 Thread support library [thread]

30.1 General [thread.general]

1

The following subclauses describe components to create and manage threads (1.859), perform mutual exclusion, and communicate conditions and values between threads, as summarized in Table 149.

Table 149 — Thread support library summary

	Subclause	Header(s)
30.3	Requirements	
30.25	Threads	`<thread>`
30.90	Mutual exclusion	`<mutex>` `<shared_mutex>`
30.157	Condition variables	`<condition_variable>`
30.179	Futures	`<future>`

30.3 Requirements [thread.req]

30.3.1 Template parameter names [thread.req.paramname]

1 Throughout this Clause, the names of template parameters are used to express type requirements. If a template parameter is named `Predicate`, `operator()` applied to the template argument shall return a value that is convertible to `bool`.

30.3.2 Exceptions [thread.req.exception]

1

Some functions described in this Clause are specified to throw exceptions of type `system_error` (19.24.4). Such exceptions shall be thrown if any of the function's error conditions is detected or a call to an operating system or other underlying API results in an error that prevents the library function from meeting its specifications. Failure to allocate storage shall be reported as described in 17.677.0.1.

[*Example:* Consider a function in this clause that is specified to throw exceptions of type `system_error` and specifies error conditions that include `operation_not_permitted` for a thread that does not have the privilege to perform the operation. Assume that, during the execution of this function, an `errno` of `EPERM` is reported by a POSIX API call used by the implementation. Since POSIX specifies an `errno` of `EPERM` when "the caller does not have the privilege to perform the operation", the implementation maps `EPERM` to an `error_condition` of `operation_not_permitted` (19.14) and an exception of type `system_error` is thrown. — *end example*]

1 The `error_code` reported by such an exception's `code()` member function shall compare equal to one of the conditions specified in the function's error condition element.

30.6.1 Native handles [thread.req.native]

1

Several classes described in this Clause have members `native_handle_type` and `native_handle`. The presence of these members and their semantics is implementation-defined. [*Note:* These members allow

implementations to provide access to implementation details. Their names are specified to facilitate portable compile-time detection. Actual use of these members is inherently non-portable. — *end note*]

30.8.1 Timing specifications [thread.req.timing]

1 Several functions described in this Clause take an argument to specify a timeout. These timeouts are specified as either a `duration` or a `time_point` type as specified in 20.578.

2

Implementations necessarily have some delay in returning from a timeout. Any overhead in interrupt response, function return, and scheduling induces a "quality of implementation" delay, expressed as duration D_i. Ideally, this delay would be zero. Further, any contention for processor and memory resources induces a "quality of management" delay, expressed as duration D_m. The delay durations may vary from timeout to timeout, but in all cases shorter is better.

1

The member functions whose names end in `_for` take an argument that specifies a duration. These functions produce relative timeouts. Implementations should use a steady clock to measure time for these functions.[336] Given a duration argument D_t, the real-time duration of the timeout is $D_t + D_i + D_m$.

1

The member functions whose names end in `_until` take an argument that specifies a time point. These functions produce absolute timeouts. Implementations should use the clock specified in the time point to measure time for these functions. Given a clock time point argument C_t, the clock time point of the return from timeout should be $C_t + D_i + D_m$ when the clock is not adjusted during the timeout. If the clock is adjusted to the time C_a during the timeout, the behavior should be as follows:

— if $C_a > C_t$, the waiting function should wake as soon as possible, i.e. $C_a + D_i + D_m$, since the timeout is already satisfied. [*Note:* This specification may result in the total duration of the wait decreasing when measured against a steady clock. — *end note*]

— if $C_a <= C_t$, the waiting function should not time out until `Clock::now()` returns a time $C_n >= C_t$, i.e. waking at $C_t + D_i + D_m$. [*Note:* When the clock is adjusted backwards, this specification may result in the total duration of the wait increasing when measured against a steady clock. When the clock is adjusted forwards, this specification may result in the total duration of the wait decreasing when measured against a steady clock. — *end note*]

An implementation shall return from such a timeout at any point from the time specified above to the time it would return from a steady-clock relative timeout on the difference between C_t and the time point of the call to the `_until` function. [*Note:* Implementations should decrease the duration of the wait when the clock is adjusted forwards. — *end note*]

1

[*Note:* If the clock is not synchronized with a steady clock, e.g., a CPU time clock, these timeouts might not provide useful functionality. — *end note*]

1 The resolution of timing provided by an implementation depends on both operating system and hardware. The finest resolution provided by an implementation is called the *native resolution*.

2 Implementation-provided clocks that are used for these functions shall meet the `TrivialClock` requirements (20.578.3).

3 A function that takes an argument which specifies a timeout will throw if, during its execution, a clock, time point, or time duration throws an exception. Such exceptions are referred to as *timeout-related exceptions*.

336) All implementations for which standard time units are meaningful must necessarily have a steady clock within their hardware implementation.

[*Note:* instantiations of clock, time point and duration types supplied by the implementation as specified in 20.591.2 do not throw exceptions. — *end note*]

30.16.1 Requirements for Lockable types [thread.req.lockable]

30.16.1.1 In general [thread.req.lockable.general]

1

An *execution agent* is an entity such as a thread that may perform work in parallel with other execution agents. [*Note:* Implementations or users may introduce other kinds of agents such as processes or thread-pool tasks. — *end note*] The calling agent is determined by context, e.g. the calling thread that contains the call, and so on.

1 [*Note:* Some lockable objects are "agent oblivious" in that they work for any execution agent model because they do not determine or store the agent's ID (e.g., an ordinary spin lock). — *end note*]

2 The standard library templates `unique_lock` (30.143.0.1), `lock_guard` (30.142.1.1), `lock`, `try_lock` (30.146.1), and `condition_variable_any` (30.177.1) all operate on user-supplied lockable objects. The `BasicLockable` requirements, the `Lockable` requirements, and the `TimedLockable` requirements list the requirements imposed by these library types in order to acquire or release ownership of a `lock` by a given execution agent. [*Note:* The nature of any lock ownership and any synchronization it may entail are not part of these requirements. — *end note*]

30.17.0.1 `BasicLockable` requirements [thread.req.lockable.basic]

1

A type `L` meets the `BasicLockable` requirements if the following expressions are well-formed and have the specified semantics (`m` denotes a value of type `L`).

`m.lock()`

1

Effects: Blocks until a lock can be acquired for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

`m.unlock()`

1 *Requires:* The current execution agent shall hold a lock on `m`.

2 *Effects:* Releases a lock on `m` held by the current execution agent.

3 *Throws:* Nothing.

30.19.0.1 `Lockable` requirements [thread.req.lockable.req]

1 A type `L` meets the `Lockable` requirements if it meets the `BasicLockable` requirements and the following expressions are well-formed and have the specified semantics (`m` denotes a value of type `L`).

`m.try_lock()`

2 *Effects:* attempts to acquire a lock for the current execution agent without blocking. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

3 *Return type:* `bool`.

4

Returns: `true` if the lock was acquired, `false` otherwise.

30.21.0.1 `TimedLockable` requirements [thread.req.lockable.timed]

1 A type `L` meets the `TimedLockable` requirements if it meets the `Lockable` requirements and the following expressions are well-formed and have the specified semantics (`m` denotes a value of type `L`, `rel_time` denotes a value of an instantiation of `duration` (20.585.2), and `abs_time` denotes a value of an instantiation of `time_point` (20.591.1)).

`m.try_lock_for(rel_time)`

2 *Effects:* attempts to acquire a lock for the current execution agent within the relative timeout (30.8.1) specified by `rel_time`. The function shall not return within the timeout specified by `rel_time` unless it has obtained a lock on `m` for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

3 *Return type:* `bool`.

4 *Returns:* `true` if the lock was acquired, `false` otherwise.

`m.try_lock_until(abs_time)`

5 *Effects:* attempts to acquire a lock for the current execution agent before the absolute timeout (30.8.1) specified by `abs_time`. The function shall not return before the timeout specified by `abs_time` unless it has obtained a lock on `m` for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

6 *Return type:* `bool`.

7 *Returns:* `true` if the lock was acquired, `false` otherwise.

30.21.1 `decay_copy` [thread.decaycopy]

1

In several places in this Clause the operation *DECAY_COPY(x)* is used. All such uses mean call the function `decay_copy(x)` and use the result, where `decay_copy` is defined as follows:

```
template <class T> decay_t<T> decay_copy(T&& v)
  { return std::forward<T>(v); }
```

30.25 Threads [thread.threads]

1 30.25 describes components that can be used to create and manage threads. [*Note:* These threads are intended to map one-to-one with operating system threads. — *end note*]

Header `<thread>` synopsis

```
namespace std {
  class thread;

  void swap(thread& x, thread& y) noexcept;

  namespace this_thread {
    thread::id get_id() noexcept;

    void yield() noexcept;
    template <class Clock, class Duration>
      void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);
    template <class Rep, class Period>
      void sleep_for(const chrono::duration<Rep, Period>& rel_time);
  }
}
```

30.25.1 Class `thread` [thread.thread.class]

1

The class `thread` provides a mechanism to create a new thread of execution, to join with a thread (i.e., wait for a thread to complete), and to perform other operations that manage and query the state of a thread. A `thread` object uniquely represents a particular thread of execution. That representation may be transferred to other `thread` objects in such a way that no two `thread` objects simultaneously represent the same thread of execution. A thread of execution is *detached* when no `thread` object represents that thread. Objects of class `thread` can be in a state that does not represent a thread of execution. [*Note:* A `thread` object does not represent a thread of execution after default construction, after being moved from, or after a successful call to `detach` or `join`. — *end note*]

```
namespace std {
  class thread {
  public:
    // types:
    class id;
    typedef implementation-defined native_handle_type; // See 30.6.1

    // construct/copy/destroy:
    thread() noexcept;
    template <class F, class ...Args> explicit thread(F&& f, Args&&... args);
    ~thread();
    thread(const thread&) = delete;
    thread(thread&&) noexcept;
    thread& operator=(const thread&) = delete;
    thread& operator=(thread&&) noexcept;

    // members:
    void swap(thread&) noexcept;
    bool joinable() const noexcept;
    void join();
    void detach();
    id get_id() const noexcept;
    native_handle_type native_handle(); // See 30.6.1

    // static members:
    static unsigned hardware_concurrency() noexcept;
  };
}
```

30.27.0.1 Class `thread::id` [thread.thread.id]

```
namespace std {
  class thread::id {
  public:
      id() noexcept;
  };

  bool operator==(thread::id x, thread::id y) noexcept;
  bool operator!=(thread::id x, thread::id y) noexcept;
  bool operator<(thread::id x, thread::id y) noexcept;
  bool operator<=(thread::id x, thread::id y) noexcept;
  bool operator>(thread::id x, thread::id y) noexcept;
  bool operator>=(thread::id x, thread::id y) noexcept;
```

```
  template<class charT, class traits>
    basic_ostream<charT, traits>&
      operator<< (basic_ostream<charT, traits>& out, thread::id id);

  // Hash support
  template <class T> struct hash;
  template <> struct hash<thread::id>;
}
```

1 An object of type `thread::id` provides a unique identifier for each thread of execution and a single distinct value for all `thread` objects that do not represent a thread of execution (30.25.1). Each thread of execution has an associated `thread::id` object that is not equal to the `thread::id` object of any other thread of execution and that is not equal to the `thread::id` object of any `std::thread` object that does not represent threads of execution.

1

`thread::id` shall be a trivially copyable class (Clause 9). The library may reuse the value of a `thread::id` of a terminated thread that can no longer be joined.

1 [*Note:* Relational operators allow `thread::id` objects to be used as keys in associative containers. — *end note*]

`id() noexcept;`

2 *Effects:* Constructs an object of type `id`.

3 *Postconditions:* The constructed object does not represent a thread of execution.

`bool operator==(thread::id x, thread::id y) noexcept;`

4 *Returns:* `true` only if `x` and `y` represent the same thread of execution or neither `x` nor `y` represents a thread of execution.

`bool operator!=(thread::id x, thread::id y) noexcept;`

5 *Returns:* `!(x == y)`

`bool operator<(thread::id x, thread::id y) noexcept;`

6 *Returns:* A value such that `operator<` is a total ordering as described in 25.98.

`bool operator<=(thread::id x, thread::id y) noexcept;`

7 *Returns:* `!(y < x)`

`bool operator>(thread::id x, thread::id y) noexcept;`

8 *Returns:* `y < x`

`bool operator>=(thread::id x, thread::id y) noexcept;`

9 *Returns:* `!(x < y)`

```
template<class charT, class traits>
  basic_ostream<charT, traits>&
    operator<< (basic_ostream<charT, traits>&& out, thread::id id);
```

10 *Effects:* Inserts an unspecified text representation of `id` into `out`. For two objects of type `thread::id` `x` and `y`, if `x == y` the `thread::id` objects shall have the same text representation and if `x != y` the `thread::id` objects shall have distinct text representations.

11 *Returns:* `out`

```
template <> struct hash<thread::id>;
```

12 The template specialization shall meet the requirements of class template `hash` (20.443.1).

30.31.0.1 `thread` constructors [thread.thread.constr]

```
thread() noexcept;
```

1 *Effects:* Constructs a `thread` object that does not represent a thread of execution.

2 *Postcondition:* `get_id() == id()`

```
template <class F, class ...Args> explicit thread(F&& f, Args&&... args);
```

1

Requires: `F` and each `Ti` in `Args` shall satisfy the `MoveConstructible` requirements. *`INVOKE`*`(`*`DECAY_COPY`*`( std::forward<F>(f)), `*`DECAY_COPY`*`(std::forward<Args>(args))...)` (20.295.1) shall be a valid expression.

1 *Remarks:* This constructor shall not participate in overload resolution if `decay_t<F>` is the same type as `std::thread`.

2

Effects: Constructs an object of type `thread`. The new thread of execution executes *`INVOKE`*`(`*`DECAY_COPY`*`( std::forward<F>(f)), `*`DECAY_COPY`*`(std::forward<Args>(args))...)` with the calls to *`DECAY_COPY`* being evaluated in the constructing thread. Any return value from this invocation is ignored. [*Note:* This implies that any exceptions not thrown from the invocation of the copy of `f` will be thrown in the constructing thread, not the new thread. — *end note*] If the invocation of *`INVOKE`*`(`*`DECAY_COPY`*`( std::forward<F>(f)), `*`DECAY_COPY`*`(std::forward<Args>(args))...)` terminates with an uncaught exception, `std::terminate` shall be called.

1 *Synchronization:* The completion of the invocation of the constructor synchronizes with the beginning of the invocation of the copy of `f`.

1 *Postconditions:* `get_id() != id()`. `*this` represents the newly started thread.

2 *Throws:* `system_error` if unable to start the new thread.

3 *Error conditions:*

— `resource_unavailable_try_again` — the system lacked the necessary resources to create another thread, or the system-imposed limit on the number of threads in a process would be exceeded.

```
thread(thread&& x) noexcept;
```

1 *Effects:* Constructs an object of type `thread` from `x`, and sets `x` to a default constructed state.

2 *Postconditions:* `x.get_id() == id()` and `get_id()` returns the value of `x.get_id()` prior to the start of construction.

30.60.0.1 `thread` destructor [thread.thread.destr]

```
~thread();
```

1

If `joinable()`, calls `std::terminate()`. Otherwise, has no effects. [*Note:* Either implicitly detaching or joining a `joinable()` thread in its destructor could result in difficult to debug correctness (for detach) or performance (for join) bugs encountered only when an exception is raised. Thus the programmer must ensure that the destructor is never executed while the thread is still joinable. — *end note*]

30.74.0.1 `thread` assignment [thread.thread.assign]

```
thread& operator=(thread&& x) noexcept;
```

1

Effects: If `joinable()`, calls `std::terminate()`. Otherwise, assigns the state of `x` to `*this` and sets `x` to a default constructed state.

1 *Postconditions:* `x.get_id() == id()` and `get_id()` returns the value of `x.get_id()` prior to the assignment.

2 *Returns:* `*this`

30.75.0.1 `thread` members [thread.thread.member]

```
void swap(thread& x) noexcept;
```

1 *Effects:* Swaps the state of `*this` and `x`.

```
bool joinable() const noexcept;
```

2 *Returns:* `get_id() != id()`

```
void join();
```

3 *Requires:* `joinable()` is `true`.

4

Effects: Blocks until the thread represented by `*this` has completed.

1

Synchronization: The completion of the thread represented by `*this` synchronizes with (1.859) the corresponding successful `join()` return. [*Note:* Operations on `*this` are not synchronized. — *end note*]

1 *Postconditions:* The thread represented by `*this` has completed. `get_id() == id()`.

2

Throws: `system_error` when an exception is required (30.3.2).

1 *Error conditions:*

(1.1) — `resource_deadlock_would_occur` — if deadlock is detected or `this->get_id() == std::this_thread::get_id()`.

(1.2) — `no_such_process` — if the thread is not valid.

(1.3) — `invalid_argument` — if the thread is not joinable.

```
void detach();
```

2 *Requires:* `joinable()` is `true`.

3

Effects: The thread represented by `*this` continues execution without the calling thread blocking. When `detach()` returns, `*this` no longer represents the possibly continuing thread of execution. When the thread previously represented by `*this` ends execution, the implementation shall release any owned resources.

1 *Postcondition:* `get_id() == id()`.

2 *Throws:* `system_error` when an exception is required (30.3.2).

3 *Error conditions:*

(3.1) — `no_such_process` — if the thread is not valid.

(3.2) — `invalid_argument` — if the thread is not joinable.

```
id get_id() const noexcept;
```

4 *Returns:* A default constructed `id` object if `*this` does not represent a thread, otherwise `this_thread::get_id()` for the thread of execution represented by `*this`.

30.85.0.1 `thread` static members [thread.thread.static]

```
unsigned hardware_concurrency() noexcept;
```

1 *Returns:* The number of hardware thread contexts. [*Note:* This value should only be considered to be a hint. — *end note*] If this value is not computable or well defined an implementation should return 0.

30.85.0.2 `thread` specialized algorithms [thread.thread.algorithm]

```
void swap(thread& x, thread& y) noexcept;
```

1 *Effects:* `x.swap(y)`

30.85.1 Namespace `this_thread` [thread.thread.this]

```
namespace std {
  namespace this_thread {
    thread::id get_id() noexcept;

    void yield() noexcept;
    template <class Clock, class Duration>
      void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);
    template <class Rep, class Period>
      void sleep_for(const chrono::duration<Rep, Period>& rel_time);
  }
}
```

```
thread::id this_thread::get_id() noexcept;
```

1 *Returns:* An object of type `thread::id` that uniquely identifies the current thread of execution. No other thread of execution shall have this id and this thread of execution shall always have this id. The object returned shall not compare equal to a default constructed `thread::id`.

```
void this_thread::yield() noexcept;
```

2

Effects: Offers the implementation the opportunity to reschedule.

1 *Synchronization:* None.

```
template <class Clock, class Duration>
  void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);
```

2 *Effects:* Blocks the calling thread for the absolute timeout (30.8.1) specified by `abs_time`.

3 *Synchronization:* None.

4 *Throws:* Timeout-related exceptions (30.8.1).

```
template <class Rep, class Period>
  void sleep_for(const chrono::duration<Rep, Period>& rel_time);
```

5

Effects: Blocks the calling thread for the relative timeout (30.8.1) specified by `rel_time`.

1 *Synchronization:* None.

2 *Throws:* Timeout-related exceptions (30.8.1).

30.90 Mutual exclusion [thread.mutex]

1 This section provides mechanisms for mutual exclusion: mutexes, locks, and call once. These mechanisms ease the production of race-free programs (1.859).

Header `<mutex>` synopsis

```
namespace std {
  class mutex;
  class recursive_mutex;
  class timed_mutex;
  class recursive_timed_mutex;

  struct defer_lock_t { };
  struct try_to_lock_t { };
  struct adopt_lock_t { };

  constexpr defer_lock_t  defer_lock { };
  constexpr try_to_lock_t try_to_lock { };
  constexpr adopt_lock_t  adopt_lock { };

  template <class Mutex> class lock_guard;
  template <class Mutex> class unique_lock;

  template <class Mutex>
    void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;

  template <class L1, class L2, class... L3> int try_lock(L1&, L2&, L3&...);
  template <class L1, class L2, class... L3> void lock(L1&, L2&, L3&...);

  struct once_flag {
    constexpr once_flag() noexcept;

    once_flag(const once_flag&) = delete;
    once_flag& operator=(const once_flag&) = delete;
  };

  template<class Callable, class ...Args>
    void call_once(once_flag& flag, Callable&& func, Args&&... args);
}
```

Header `<shared_mutex>` synopsis

```
namespace std {
  class shared_timed_mutex;
  template <class Mutex> class shared_lock;
  template <class Mutex>
    void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
}
```

30.90.1 Mutex requirements [thread.mutex.requirements]

30.90.1.1 In general [thread.mutex.requirements.general]

1

A mutex object facilitates protection against data races and allows safe synchronization of data between execution agents (30.16.1). An execution agent *owns* a mutex from the time it successfully calls one of the lock functions until it calls unlock. Mutexes can be either recursive or non-recursive, and can grant simultaneous ownership to one or many execution agents. Both recursive and non-recursive mutexes are supplied.

30.92.0.1 Mutex types [thread.mutex.requirements.mutex]

1 The *mutex types* are the standard library types `std::mutex`, `std::recursive_mutex`, `std::timed_mutex`, `std::recursive_timed_mutex`, and `std::shared_timed_mutex`. They shall meet the requirements set out in this section. In this description, `m` denotes an object of a mutex type.

2

The mutex types shall meet the `Lockable` requirements (30.19.0.1).

1

The mutex types shall be `DefaultConstructible` and `Destructible`. If initialization of an object of a mutex type fails, an exception of type `system_error` shall be thrown. The mutex types shall not be copyable or movable.

1

The error conditions for error codes, if any, reported by member functions of the mutex types shall be:

— `resource_unavailable_try_again` — if any native handle type manipulated is not available.

— `operation_not_permitted` — if the thread does not have the privilege to perform the operation.

— `device_or_resource_busy` — if any native handle type manipulated is already locked.

— `invalid_argument` — if any native handle type manipulated as part of mutex construction is incorrect.

1 The implementation shall provide lock and unlock operations, as described below. For purposes of determining the existence of a data race, these behave as atomic operations (1.859). The lock and unlock operations on a single mutex shall appear to occur in a single total order. [*Note:* this can be viewed as the modification order (1.859) of the mutex. — *end note*] [*Note:* Construction and destruction of an object of a mutex type need not be thread-safe; other synchronization should be used to ensure that mutex objects are initialized and visible to other threads. — *end note*]

2

The expression `m.lock()` shall be well-formed and have the following semantics:

1

Requires: If `m` is of type `std::mutex`, `std::timed_mutex`, or `std::shared_timed_mutex`, the calling thread does not own the mutex.

1 *Effects:* Blocks the calling thread until ownership of the mutex can be obtained for the calling thread.

2 *Postcondition:* The calling thread owns the mutex.

3 *Return type:* `void`

4 *Synchronization:* Prior `unlock()` operations on the same object shall *synchronize with* (1.859) this operation.

5 *Throws:* `system_error` when an exception is required (30.3.2).

6 *Error conditions:*

— `operation_not_permitted` — if the thread does not have the privilege to perform the operation.

— `resource_deadlock_would_occur` — if the implementation detects that a deadlock would occur.

— `device_or_resource_busy` — if the mutex is already locked and blocking is not possible.

1 The expression `m.try_lock()` shall be well-formed and have the following semantics:

2 *Requires:* If `m` is of type `std::mutex`, `std::timed_mutex`, or `std::shared_timed_mutex`, the calling thread does not own the mutex.

3 *Effects:* Attempts to obtain ownership of the mutex for the calling thread without blocking. If ownership is not obtained, there is no effect and `try_lock()` immediately returns. An implementation may fail to obtain the lock even if it is not held by any other thread. [*Note:* This spurious failure is normally uncommon, but allows interesting implementations based on a simple compare and exchange (Clause 29). — *end note*] An implementation should ensure that `try_lock()` does not consistently return `false` in the absence of contending mutex acquisitions.

1 *Return type:* `bool`

2 *Returns:* `true` if ownership of the mutex was obtained for the calling thread, otherwise `false`.

3 *Synchronization:* If `try_lock()` returns `true`, prior `unlock()` operations on the same object *synchronize with* (1.859) this operation. [*Note:* Since `lock()` does not synchronize with a failed subsequent `try_lock()`, the visibility rules are weak enough that little would be known about the state after a failure, even in the absence of spurious failures. — *end note*]

1 *Throws:* Nothing.

2

The expression `m.unlock()` shall be well-formed and have the following semantics:

1 *Requires:* The calling thread shall own the mutex.

2 *Effects:* Releases the calling thread's ownership of the mutex.

1 *Return type:* `void`

2 *Synchronization:* This operation synchronizes with (1.859) subsequent lock operations that obtain ownership on the same object.

1 *Throws:* Nothing.

30.125.0.0.1 Class `mutex` [thread.mutex.class]

```
namespace std {
  class mutex {
  public:
    constexpr mutex() noexcept;
    ~mutex();

    mutex(const mutex&) = delete;
    mutex& operator=(const mutex&) = delete;
```

```
    void lock();
    bool try_lock();
    void unlock();

    typedef implementation-defined native_handle_type; // See 30.6.1
    native_handle_type native_handle();                // See 30.6.1
  };
}
```

1

The class `mutex` provides a non-recursive mutex with exclusive ownership semantics. If one thread owns a mutex object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()`) or block (for `lock()`) until the owning thread has released ownership with a call to `unlock()`.

1 [*Note:* After a thread `A` has called `unlock()`, releasing a mutex, it is possible for another thread `B` to lock the same mutex, observe that it is no longer in use, unlock it, and destroy it, before thread `A` appears to have returned from its unlock call. Implementations are required to handle such scenarios correctly, as long as thread `A` doesn't access the mutex after the unlock call returns. These cases typically occur when a reference-counted object contains a mutex that is used to protect the reference count. — *end note*]

2 The class `mutex` shall satisfy all the `Mutex` requirements (30.90.1). It shall be a standard-layout class (Clause 9).

3

[*Note:* A program may deadlock if the thread that owns a `mutex` object calls `lock()` on that object. If the implementation can detect the deadlock, a `resource_deadlock_would_occur` error condition may be observed. — *end note*]

1

The behavior of a program is undefined if it destroys a `mutex` object owned by any thread or a thread terminates while owning a `mutex` object.

30.134.0.0.1 Class `recursive_mutex` [thread.mutex.recursive]

```
namespace std {
  class recursive_mutex {
  public:
    recursive_mutex();
    ~recursive_mutex();

    recursive_mutex(const recursive_mutex&) = delete;
    recursive_mutex& operator=(const recursive_mutex&) = delete;

    void lock();
    bool try_lock() noexcept;
    void unlock();

    typedef implementation-defined native_handle_type; // See 30.6.1
    native_handle_type native_handle();                // See 30.6.1
  };
}
```

1 The class `recursive_mutex` provides a recursive mutex with exclusive ownership semantics. If one thread owns a `recursive_mutex` object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()`) or block (for `lock()`) until the first thread has completely released ownership.

2 The class `recursive_mutex` shall satisfy all the Mutex requirements (30.90.1). It shall be a standard-layout class (Clause 9).

3

A thread that owns a `recursive_mutex` object may acquire additional levels of ownership by calling `lock()` or `try_lock()` on that object. It is unspecified how many levels of ownership may be acquired by a single thread. If a thread has already acquired the maximum level of ownership for a `recursive_mutex` object, additional calls to `try_lock()` shall fail, and additional calls to `lock()` shall throw an exception of type `system_error`. A thread shall call `unlock()` once for each level of ownership acquired by calls to `lock()` and `try_lock()`. Only when all levels of ownership have been released may ownership be acquired by another thread.

1 The behavior of a program is undefined if:

(1.1) — it destroys a `recursive_mutex` object owned by any thread or

(1.2) — a thread terminates while owning a `recursive_mutex` object.

30.135.0.1 Timed mutex types [thread.timedmutex.requirements]

1 The *timed mutex types* are the standard library types `std::timed_mutex`, `std::recursive_timed_mutex`, and `std::shared_timed_mutex`. They shall meet the requirements set out below. In this description, `m` denotes an object of a mutex type, `rel_time` denotes an object of an instantiation of `duration` (20.585.2), and `abs_time` denotes an object of an instantiation of `time_point` (20.591.1).

2 The timed mutex types shall meet the `TimedLockable` requirements (30.21.0.1).

3 The expression `m.try_lock_for(rel_time)` shall be well-formed and have the following semantics:

4 *Requires:* If `m` is of type `std::timed_mutex` or `std::shared_timed_mutex`, the calling thread does not own the mutex.

5 *Effects:* The function attempts to obtain ownership of the mutex within the relative timeout (30.8.1) specified by `rel_time`. If the time specified by `rel_time` is less than or equal to `rel_time.zero()`, the function attempts to obtain ownership without blocking (as if by calling `try_lock()`). The function shall return within the timeout specified by `rel_time` only if it has obtained ownership of the mutex object. [*Note:* As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — *end note*]

6 *Return type:* `bool`

7 *Returns:* `true` if ownership was obtained, otherwise `false`.

8 *Synchronization:* If `try_lock_for()` returns `true`, prior `unlock()` operations on the same object *synchronize with* (1.859) this operation.

9 *Throws:* Timeout-related exceptions (30.8.1).

10 The expression `m.try_lock_until(abs_time)` shall be well-formed and have the following semantics:

11 *Requires:* If `m` is of type `std::timed_mutex` or `std::shared_timed_mutex`, the calling thread does not own the mutex.

12 *Effects:* The function attempts to obtain ownership of the mutex. If `abs_time` has already passed, the function attempts to obtain ownership without blocking (as if by calling `try_lock()`). The function shall return before the absolute timeout (30.8.1) specified by `abs_time` only if it has obtained ownership of the mutex object. [*Note:* As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — *end note*]

13 *Return type:* `bool`

14 *Returns:* `true` if ownership was obtained, otherwise `false`.

15 *Synchronization:* If `try_lock_until()` returns `true`, prior `unlock()` operations on the same object *synchronize with* (1.859) this operation.

16 *Throws:* Timeout-related exceptions (30.8.1).

30.135.0.1.1 Class `timed_mutex` [thread.timedmutex.class]

```
namespace std {
  class timed_mutex {
  public:
    timed_mutex();
    ~timed_mutex();

    timed_mutex(const timed_mutex&) = delete;
    timed_mutex& operator=(const timed_mutex&) = delete;

    void lock();  // blocking
    bool try_lock();
    template <class Rep, class Period>
      bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
    template <class Clock, class Duration>
      bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
    void unlock();

    typedef implementation-defined native_handle_type; // See 30.6.1
    native_handle_type native_handle();                // See 30.6.1
  };
}
```

1 The class `timed_mutex` provides a non-recursive mutex with exclusive ownership semantics. If one thread owns a `timed_mutex` object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()`) or block (for `lock()`, `try_lock_for()`, and `try_lock_until()`) until the owning thread has released ownership with a call to `unlock()` or the call to `try_lock_for()` or `try_lock_until()` times out (having failed to obtain ownership).

2 The class `timed_mutex` shall satisfy all of the `TimedMutex` requirements (30.135.0.1). It shall be a standard-layout class (Clause 9).

3 The behavior of a program is undefined if:

(3.1) — it destroys a `timed_mutex` object owned by any thread,

(3.2) — a thread that owns a `timed_mutex` object calls `lock()`, `try_lock()`, `try_lock_for()`, or `try_lock_until()` on that object, or

(3.3) — a thread terminates while owning a `timed_mutex` object.

30.135.0.1.2 Class `recursive_timed_mutex` [thread.timedmutex.recursive]

```
namespace std {
  class recursive_timed_mutex {
  public:
    recursive_timed_mutex();
    ~recursive_timed_mutex();

    recursive_timed_mutex(const recursive_timed_mutex&) = delete;
    recursive_timed_mutex& operator=(const recursive_timed_mutex&) = delete;
```

```
    void lock();  // blocking
    bool try_lock() noexcept;
    template <class Rep, class Period>
      bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
    template <class Clock, class Duration>
      bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
    void unlock();

    typedef implementation-defined native_handle_type; // See 30.6.1
    native_handle_type native_handle();                // See 30.6.1
  };
}
```

1 The class `recursive_timed_mutex` provides a recursive mutex with exclusive ownership semantics. If one thread owns a `recursive_timed_mutex` object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()`) or block (for `lock()`, `try_lock_for()`, and `try_lock_until()`) until the owning thread has completely released ownership or the call to `try_lock_for()` or `try_lock_until()` times out (having failed to obtain ownership).

2 The class `recursive_timed_mutex` shall satisfy all of the `TimedMutex` requirements (30.135.0.1). It shall be a standard-layout class (Clause 9).

3 A thread that owns a `recursive_timed_mutex` object may acquire additional levels of ownership by calling `lock()`, `try_lock()`, `try_lock_for()`, or `try_lock_until()` on that object. It is unspecified how many levels of ownership may be acquired by a single thread. If a thread has already acquired the maximum level of ownership for a `recursive_timed_mutex` object, additional calls to `try_lock()`, `try_lock_for()`, or `try_lock_until()` shall fail, and additional calls to `lock()` shall throw an exception of type `system_error`. A thread shall call `unlock()` once for each level of ownership acquired by calls to `lock()`, `try_lock()`, `try_lock_for()`, and `try_lock_until()`. Only when all levels of ownership have been released may ownership of the object be acquired by another thread.

4 The behavior of a program is undefined if:

(4.1) — it destroys a `recursive_timed_mutex` object owned by any thread, or

(4.2) — a thread terminates while owning a `recursive_timed_mutex` object.

30.135.0.2 Shared timed mutex types [thread.sharedtimedmutex.requirements]

1 The standard library type `std::shared_timed_mutex` is a *shared timed mutex type*. Shared timed mutex types shall meet the requirements of timed mutex types (30.135.0.1), and additionally shall meet the requirements set out below. In this description, `m` denotes an object of a mutex type, `rel_type` denotes an object of an instantiation of `duration` (20.585.2), and `abs_time` denotes an object of an instantiation of `time_point` (20.591.1).

2 In addition to the exclusive lock ownership mode specified in 30.92.0.1, shared mutex types provide a *shared lock* ownership mode. Multiple execution agents can simultaneously hold a shared lock ownership of a shared mutex type. But no execution agent shall hold a shared lock while another execution agent holds an exclusive lock on the same shared mutex type, and vice-versa. The maximum number of execution agents which can share a shared lock on a single shared mutex type is unspecified, but shall be at least 10000. If more than the maximum number of execution agents attempt to obtain a shared lock, the excess execution agents shall block until the number of shared locks are reduced below the maximum amount by other execution agents releasing their shared lock.

3 The expression `m.lock_shared()` shall be well-formed and have the following semantics:

4 *Requires:* The calling thread has no ownership of the mutex.

5

Effects: Blocks the calling thread until shared ownership of the mutex can be obtained for the calling thread. If an exception is thrown then a shared lock shall not have been acquired for the current thread.

1 *Postcondition:* The calling thread has a shared lock on the mutex.

2 *Return type:* `void`.

3

Synchronization: Prior `unlock()` operations on the same object shall synchronize with (1.859) this operation.

1 *Throws:* `system_error` when an exception is required (30.3.2).

2 *Error conditions:*

(2.1) — `operation_not_permitted` — if the thread does not have the privilege to perform the operation.

(2.2) — `resource_deadlock_would_occur` — if the implementation detects that a deadlock would occur.

(2.3) — `device_or_resource_busy` — if the mutex is already locked and blocking is not possible.

3 The expression `m.unlock_shared()` shall be well-formed and have the following semantics:

4 *Requires:* The calling thread shall hold a shared lock on the mutex.

5 *Effects:* Releases a shared lock on the mutex held by the calling thread.

6 *Return type:* `void`.

7 *Synchronization:* This operation synchronizes with (1.859) subsequent `lock()` operations that obtain ownership on the same object.

8 *Throws:* Nothing.

9 The expression `m.try_lock_shared()` shall be well-formed and have the following semantics:

10 *Requires:* The calling thread has no ownership of the mutex.

11 *Effects:* Attempts to obtain shared ownership of the mutex for the calling thread without blocking. If shared ownership is not obtained, there is no effect and `try_lock_shared()` immediately returns. An implementation may fail to obtain the lock even if it is not held by any other thread.

12 *Return type:* `bool`.

13 *Returns:* `true` if the shared ownership lock was acquired, `false` otherwise.

14 *Synchronization:* If `try_lock_shared()` returns `true`, prior `unlock()` operations on the same object synchronize with (1.859) this operation.

15 *Throws:* Nothing.

16 The expression `m.try_lock_shared_for(rel_time)` shall be well-formed and have the following semantics:

17 *Requires:* The calling thread has no ownership of the mutex.

18 *Effects:* Attempts to obtain shared lock ownership for the calling thread within the relative timeout (30.8.1) specified by `rel_time`. If the time specified by `rel_time` is less than or equal to `rel_time.zero()`, the function attempts to obtain ownership without blocking (as if by calling `try_lock_shared()`). The function shall return within the timeout specified by `rel_time` only if it has obtained shared ownership of the mutex object. [*Note:* As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — *end note*] If an exception is thrown then a shared lock shall not have been acquired for the current thread.

19 *Return type:* `bool`.

20 *Returns:* `true` if the shared lock was acquired, `false` otherwise.

21 *Synchronization:* If `try_lock_shared_for()` returns `true`, prior `unlock()` operations on the same object synchronize with (1.859) this operation.

22 *Throws:* Timeout-related exceptions (30.8.1).

23 The expression `m.try_lock_shared_until(abs_time)` shall be well-formed and have the following semantics:

24 *Requires:* The calling thread has no ownership of the mutex.

25 *Effects:* The function attempts to obtain shared ownership of the mutex. If `abs_time` has already passed, the function attempts to obtain shared ownership without blocking (as if by calling `try_lock_shared()`). The function shall return before the absolute timeout (30.8.1) specified by `abs_time` only if it has obtained shared ownership of the mutex object. [*Note:* As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — *end note*] If an exception is thrown then a shared lock shall not have been acquired for the current thread.

26 *Return type:* `bool`.

27 *Returns:* `true` if the shared lock was acquired, `false` otherwise.

28 *Synchronization:* If `try_lock_shared_until()` returns `true`, prior `unlock()` operations on the same object synchronize with (1.859) this operation.

29 *Throws:* Timeout-related exceptions (30.8.1).

30.142.0.0.1 Class `shared_timed_mutex` [thread.sharedtimedmutex.class]

```
namespace std {
  class shared_timed_mutex {
  public:
    shared_timed_mutex();
    ~shared_timed_mutex();

    shared_timed_mutex(const shared_timed_mutex&) = delete;
    shared_timed_mutex& operator=(const shared_timed_mutex&) = delete;

    // Exclusive ownership
    void lock();  // blocking
    bool try_lock();
    template <class Rep, class Period>
      bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
    template <class Clock, class Duration>
      bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
    void unlock();

    // Shared ownership
    void lock_shared();  // blocking
    bool try_lock_shared();
    template <class Rep, class Period>
      bool
      try_lock_shared_for(const chrono::duration<Rep, Period>& rel_time);
    template <class Clock, class Duration>
      bool
      try_lock_shared_until(const chrono::time_point<Clock, Duration>& abs_time);
```

```
    void unlock_shared();
  };
}
```

1 The class `shared_timed_mutex` provides a non-recursive mutex with shared ownership semantics.

2 The class `shared_timed_mutex` shall satisfy all of the `SharedTimedMutex` requirements (30.135.0.2). It shall be a standard-layout class (Clause 9).

3 The behavior of a program is undefined if:

(3.1) — it destroys a `shared_timed_mutex` object owned by any thread,

(3.2) — a thread attempts to recursively gain any ownership of a `shared_timed_mutex`, or

(3.3) — a thread terminates while possessing any ownership of a `shared_timed_mutex`.

30.142.1 Locks [thread.lock]

1 A *lock* is an object that holds a reference to a lockable object and may unlock the lockable object during the lock's destruction (such as when leaving block scope). An execution agent may use a lock to aid in managing ownership of a lockable object in an exception safe manner. A lock is said to *own* a lockable object if it is currently managing the ownership of that lockable object for an execution agent. A lock does not manage the lifetime of the lockable object it references. [*Note:* Locks are intended to ease the burden of unlocking the lockable object under both normal and exceptional circumstances. — *end note*]

2 Some lock constructors take tag types which describe what should be done with the lockable object during the lock's construction.

```
namespace std {
  struct defer_lock_t  { };     // do not acquire ownership of the mutex
  struct try_to_lock_t { };     // try to acquire ownership of the mutex
                                // without blocking
  struct adopt_lock_t  { };     // assume the calling thread has already
                                // obtained mutex ownership and manage it

  constexpr defer_lock_t   defer_lock { };
  constexpr try_to_lock_t  try_to_lock { };
  constexpr adopt_lock_t   adopt_lock { };
}
```

30.142.1.1 Class template `lock_guard` [thread.lock.guard]

```
namespace std {
  template <class Mutex>
  class lock_guard {
  public:
    typedef Mutex mutex_type;

    explicit lock_guard(mutex_type& m);
    lock_guard(mutex_type& m, adopt_lock_t);
    ~lock_guard();

    lock_guard(lock_guard const&) = delete;
    lock_guard& operator=(lock_guard const&) = delete;

  private:
    mutex_type& pm; // exposition only
```

```
  };
}
```

1

An object of type `lock_guard` controls the ownership of a lockable object within a scope. A `lock_guard` object maintains ownership of a lockable object throughout the `lock_guard` object's lifetime (3.2563). The behavior of a program is undefined if the lockable object referenced by `pm` does not exist for the entire lifetime of the `lock_guard` object. The supplied `Mutex` type shall meet the `BasicLockable` requirements (30.17.0.1).

`explicit lock_guard(mutex_type& m);`

1 *Requires:* If `mutex_type` is not a recursive mutex, the calling thread does not own the mutex `m`.

2 *Effects:* `m.lock()`

3 *Postcondition:* `&pm == &m`

`lock_guard(mutex_type& m, adopt_lock_t);`

4 *Requires:* The calling thread owns the mutex `m`.

5 *Postcondition:* `&pm == &m`

6 *Throws:* Nothing.

`~lock_guard();`

7 *Effects:* `pm.unlock()`

30.143.0.1 Class template `unique_lock` [thread.lock.unique]

```
namespace std {
  template <class Mutex>
  class unique_lock {
  public:
    typedef Mutex mutex_type;

    // 30.145.0.0.1, construct/copy/destroy:
    unique_lock() noexcept;
    explicit unique_lock(mutex_type& m);
    unique_lock(mutex_type& m, defer_lock_t) noexcept;
    unique_lock(mutex_type& m, try_to_lock_t);
    unique_lock(mutex_type& m, adopt_lock_t);
    template <class Clock, class Duration>
      unique_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);
    template <class Rep, class Period>
      unique_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);
    ~unique_lock();

    unique_lock(unique_lock const&) = delete;
    unique_lock& operator=(unique_lock const&) = delete;

    unique_lock(unique_lock&& u) noexcept;
    unique_lock& operator=(unique_lock&& u);

    // 30.146.0.0.1, locking:
    void lock();
    bool try_lock();
```

```
    template <class Rep, class Period>
      bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
    template <class Clock, class Duration>
      bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);

    void unlock();

    // 30.146.0.0.2, modifiers:
    void swap(unique_lock& u) noexcept;
    mutex_type* release() noexcept;

    // 30.146.0.0.3, observers:
    bool owns_lock() const noexcept;
    explicit operator bool () const noexcept;
    mutex_type* mutex() const noexcept;

  private:
    mutex_type* pm; // exposition only
    bool owns;      // exposition only
  };

  template <class Mutex>
    void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;
}
```

1

An object of type `unique_lock` controls the ownership of a lockable object within a scope. Ownership of the lockable object may be acquired at construction or after construction, and may be transferred, after acquisition, to another `unique_lock` object. Objects of type `unique_lock` are not copyable but are movable. The behavior of a program is undefined if the contained pointer `pm` is not null and the lockable object pointed to by `pm` does not exist for the entire remaining lifetime (3.2563) of the `unique_lock` object. The supplied `Mutex` type shall meet the `BasicLockable` requirements (30.17.0.1).

1 [*Note:* `unique_lock<Mutex>` meets the `BasicLockable` requirements. If `Mutex` meets the `Lockable` requirements (30.19.0.1), `unique_lock<Mutex>` also meets the `Lockable` requirements; if `Mutex` meets the `TimedLockable` requirements (30.21.0.1), `unique_lock<Mutex>` also meets the `TimedLockable` requirements. — *end note*]

30.145.0.0.1 `unique_lock` constructors, destructor, and assignment [thread.lock.unique.cons]

`unique_lock() noexcept;`

1 *Effects:* Constructs an object of type `unique_lock`.

2 *Postconditions:* `pm == 0` and `owns == false`.

`explicit unique_lock(mutex_type& m);`

3 *Requires:* If `mutex_type` is not a recursive mutex the calling thread does not own the mutex.

4 *Effects:* Constructs an object of type `unique_lock` and calls `m.lock()`.

5 *Postconditions:* `pm == &m` and `owns == true`.

`unique_lock(mutex_type& m, defer_lock_t) noexcept;`

6 *Effects:* Constructs an object of type `unique_lock`.

7 *Postconditions:* `pm == &m` and `owns == false`.

```
unique_lock(mutex_type& m, try_to_lock_t);
```

8

Requires: The supplied `Mutex` type shall meet the `Lockable` requirements (30.19.0.1). If `mutex_type` is not a recursive mutex the calling thread does not own the mutex.

1 *Effects:* Constructs an object of type `unique_lock` and calls `m.try_lock()`.

2 *Postconditions:* `pm == &m` and `owns == res`, where `res` is the value returned by the call to `m.try_lock()`.

```
unique_lock(mutex_type& m, adopt_lock_t);
```

3 *Requires:* The calling thread own the mutex.

4 *Effects:* Constructs an object of type `unique_lock`.

5 *Postconditions:* `pm == &m` and `owns == true`.

6 *Throws:* Nothing.

```
template <class Clock, class Duration>
  unique_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);
```

7 *Requires:* If `mutex_type` is not a recursive mutex the calling thread does not own the mutex. The supplied `Mutex` type shall meet the `TimedLockable` requirements (30.21.0.1).

8 *Effects:* Constructs an object of type `unique_lock` and calls `m.try_lock_until(abs_time)`.

9 *Postconditions:* `pm == &m` and `owns == res`, where `res` is the value returned by the call to `m.try_lock_until(abs_time)`.

```
template <class Rep, class Period>
  unique_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);
```

10 *Requires:* If `mutex_type` is not a recursive mutex the calling thread does not own the mutex. The supplied `Mutex` type shall meet the `TimedLockable` requirements (30.21.0.1).

11 *Effects:* Constructs an object of type `unique_lock` and calls `m.try_lock_for(rel_time)`.

12 *Postconditions:* `pm == &m` and `owns == res`, where `res` is the value returned by the call to `m.try_lock_for(rel_time)`.

```
unique_lock(unique_lock&& u) noexcept;
```

13 *Postconditions:* `pm == u_p.pm` and `owns == u_p.owns` (where `u_p` is the state of `u` just prior to this construction), `u.pm == 0` and `u.owns == false`.

```
unique_lock& operator=(unique_lock&& u);
```

14 *Effects:* If `owns` calls `pm->unlock()`.

15 *Postconditions:* `pm == u_p.pm` and `owns == u_p.owns` (where `u_p` is the state of `u` just prior to this construction), `u.pm == 0` and `u.owns == false`.

16 [*Note:* With a recursive mutex it is possible for both `*this` and `u` to own the same mutex before the assignment. In this case, `*this` will own the mutex after the assignment and `u` will not. — *end note*]

17 *Throws:* Nothing.

```
~unique_lock();
```

18 *Effects:* If `owns` calls `pm->unlock()`.

30.146.0.0.1 `unique_lock` locking [thread.lock.unique.locking]

```
void lock();
```

1 *Effects:* `pm->lock()`

2 *Postcondition:* `owns == true`

3 *Throws:* Any exception thrown by `pm->lock()`. `system_error` if an exception is required (30.3.2). `system_error` with an error condition of `operation_not_permitted` if `pm` is 0. `system_error` with an error condition of `resource_deadlock_would_occur` if on entry `owns` is `true`.

```
bool try_lock();
```

4 *Requires:* The supplied `Mutex` shall meet the `Lockable` requirements (30.19.0.1).

5 *Effects:* `pm->try_lock()`

6 *Returns:* The value returned by the call to `try_lock()`.

7 *Postcondition:* `owns == res`, where `res` is the value returned by the call to `try_lock()`.

8 *Throws:* Any exception thrown by `pm->try_lock()`. `system_error` if an exception is required (30.3.2). `system_error` with an error condition of `operation_not_permitted` if `pm` is 0. `system_error` with an error condition of `resource_deadlock_would_occur` if on entry `owns` is `true`.

```
template <class Clock, class Duration>
  bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
```

9 *Requires:* The supplied `Mutex` type shall meet the `TimedLockable` requirements (30.21.0.1).

10 *Effects:* `pm->try_lock_until(abs_time)`

11 *Returns:* The value returned by the call to `try_lock_until(abs_time)`.

12 *Postcondition:* `owns == res`, where `res` is the value returned by the call to `try_lock_until(abs_time)`.

13 *Throws:* Any exception thrown by `pm->try_lock_until()`. `system_error` if an exception is required (30.3.2). `system_error` with an error condition of `operation_not_permitted` if `pm` is 0. `system_error` with an error condition of `resource_deadlock_would_occur` if on entry `owns` is `true`.

```
template <class Rep, class Period>
  bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
```

14 *Requires:* The supplied `Mutex` type shall meet the `TimedLockable` requirements (30.21.0.1).

15 *Effects:* `pm->try_lock_for(rel_time)`.

16 *Returns:* The value returned by the call to `try_lock_until(rel_time)`.

17 *Postcondition:* `owns == res`, where `res` is the value returned by the call to `try_lock_for(rel_time)`.

18 *Throws:* Any exception thrown by `pm->try_lock_for()`. `system_error` if an exception is required (30.3.2). `system_error` with an error condition of `operation_not_permitted` if `pm` is 0. `system_error` with an error condition of `resource_deadlock_would_occur` if on entry `owns` is `true`.

```
void unlock();
```

19 *Effects:* `pm->unlock()`

20 *Postcondition:* `owns == false`

21 *Throws:* `system_error` when an exception is required (30.3.2).

22 *Error conditions:*

(22.1) — `operation_not_permitted` — if on entry `owns` is false.

30.146.0.0.2 `unique_lock` modifiers [thread.lock.unique.mod]

```
void swap(unique_lock& u) noexcept;
```

1 *Effects:* Swaps the data members of `*this` and `u`.

```
mutex_type* release() noexcept;
```

2 *Returns:* The previous value of `pm`.

3 *Postconditions:* `pm == 0` and `owns == false`.

```
template <class Mutex>
  void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;
```

4 *Effects:* `x.swap(y)`

30.146.0.0.3 `unique_lock` observers [thread.lock.unique.obs]

```
bool owns_lock() const noexcept;
```

1 *Returns:* `owns`

```
explicit operator bool() const noexcept;
```

2 *Returns:* `owns`

```
mutex_type *mutex() const noexcept;
```

3 *Returns:* `pm`

30.146.0.1 Class template `shared_lock` [thread.lock.shared]

```
  namespace std {

  template <class Mutex>
  class shared_lock {
  public:
    typedef Mutex mutex_type;

    // Shared locking
    shared_lock() noexcept;
    explicit shared_lock(mutex_type& m);  // blocking
    shared_lock(mutex_type& m, defer_lock_t) noexcept;
    shared_lock(mutex_type& m, try_to_lock_t);
    shared_lock(mutex_type& m, adopt_lock_t);
    template <class Clock, class Duration>
      shared_lock(mutex_type& m,
                  const chrono::time_point<Clock, Duration>& abs_time);
    template <class Rep, class Period>
      shared_lock(mutex_type& m,
                  const chrono::duration<Rep, Period>& rel_time);
    ~shared_lock();

    shared_lock(shared_lock const&) = delete;
    shared_lock& operator=(shared_lock const&) = delete;

    shared_lock(shared_lock&& u) noexcept;
    shared_lock& operator=(shared_lock&& u) noexcept;
```

```
    void lock();  // blocking
    bool try_lock();
    template <class Rep, class Period>
      bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
    template <class Clock, class Duration>
      bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
    void unlock();

    // Setters
    void swap(shared_lock& u) noexcept;
    mutex_type* release() noexcept;

    // Getters
    bool owns_lock() const noexcept;
    explicit operator bool () const noexcept;
    mutex_type* mutex() const noexcept;

  private:
    mutex_type* pm; // exposition only
    bool owns;      // exposition only
  };

  template <class Mutex>
    void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;

  }  // std
```

1 An object of type `shared_lock` controls the shared ownership of a lockable object within a scope. Shared ownership of the lockable object may be acquired at construction or after construction, and may be transferred, after acquisition, to another `shared_lock` object. Objects of type `shared_lock` are not copyable but are movable. The behavior of a program is undefined if the contained pointer `pm` is not null and the lockable object pointed to by `pm` does not exist for the entire remaining lifetime (3.2563) of the `shared_lock` object. The supplied `Mutex` type shall meet the shared mutex requirements (30.135.0.2).

2 [*Note:* `shared_lock<Mutex>` meets the `TimedLockable` requirements (30.21.0.1). — *end note*]

30.146.0.1.1 `shared_lock` constructors, destructor, and assignment [thread.lock.shared.cons]

`shared_lock() noexcept;`

1 *Effects:* Constructs an object of type `shared_lock`.

2 *Postconditions:* `pm == nullptr` and `owns == false`.

`explicit shared_lock(mutex_type& m);`

3 *Requires:* The calling thread does not own the mutex for any ownership mode.

4 *Effects:* Constructs an object of type `shared_lock` and calls `m.lock_shared()`.

5 *Postconditions:* `pm == &m` and `owns == true`.

`shared_lock(mutex_type& m, defer_lock_t) noexcept;`

6 *Effects:* Constructs an object of type `shared_lock`.

7 *Postconditions:* `pm == &m` and `owns == false`.

`shared_lock(mutex_type& m, try_to_lock_t);`

8 *Requires:* The calling thread does not own the mutex for any ownership mode.

9 *Effects:* Constructs an object of type `shared_lock` and calls `m.try_lock_shared()`.

10 *Postconditions:* `pm == &m` and `owns == res` where `res` is the value returned by the call to `m.try_lock_shared()`.

```
shared_lock(mutex_type& m, adopt_lock_t);
```

11 *Requires:* The calling thread has shared ownership of the mutex.

12 *Effects:* Constructs an object of type `shared_lock`.

13 *Postconditions:* `pm == &m` and `owns == true`.

```
template <class Clock, class Duration>
  shared_lock(mutex_type& m,
              const chrono::time_point<Clock, Duration>& abs_time);
```

14 *Requires:* The calling thread does not own the mutex for any ownership mode.

15 *Effects:* Constructs an object of type `shared_lock` and calls `m.try_lock_shared_until(abs_time)`.

16 *Postconditions:* `pm == &m` and `owns == res` where `res` is the value returned by the call to `m.try_lock_shared_until(abs_time)`.

```
template <class Rep, class Period>
  shared_lock(mutex_type& m,
              const chrono::duration<Rep, Period>& rel_time);
```

17 *Requires:* The calling thread does not own the mutex for any ownership mode.

18 *Effects:* Constructs an object of type `shared_lock` and calls `m.try_lock_shared_for(rel_time)`.

19 *Postconditions:* `pm == &m` and `owns == res` where `res` is the value returned by the call to `m.try_lock_shared_for(rel_time)`.

```
~shared_lock();
```

20 *Effects:* If `owns` calls `pm->unlock_shared()`.

```
shared_lock(shared_lock&& sl) noexcept;
```

21 *Postconditions:* `pm == &sl_p.pm` and `owns == sl_p.owns` (where `sl_p` is the state of `sl` just prior to this construction), `sl.pm == nullptr` and `sl.owns == false`.

```
shared_lock& operator=(shared_lock&& sl) noexcept;
```

22 *Effects:* If `owns` calls `pm->unlock_shared()`.

23 *Postconditions:* `pm == &sl_p.pm` and `owns == sl_p.owns` (where `sl_p` is the state of `sl` just prior to this assignment), `sl.pm == nullptr` and `sl.owns == false`.

30.146.0.1.2 `shared_lock` locking [thread.lock.shared.locking]

```
void lock();
```

1 *Effects:* `pm->lock_shared()`.

2 *Postconditions:* `owns == true`.

3 *Throws:* Any exception thrown by `pm->lock_shared()`. `system_error` if an exception is required (30.3.2). `system_error` with an error condition of `operation_not_permitted` if `pm` is `nullptr`. `system_error` with an error condition of `resource_deadlock_would_occur` if on entry `owns` is `true`.

```
bool try_lock();
```

4 *Effects:* `pm->try_lock_shared()`.

5 *Returns:* The value returned by the call to `pm->try_lock_shared()`.

6 *Postconditions:* `owns == res`, where `res` is the value returned by the call to `pm->try_lock_shared()`.

7 *Throws:* Any exception thrown by `pm->try_lock_shared()`. `system_error` if an exception is required (30.3.2). `system_error` with an error condition of `operation_not_permitted` if `pm` is `nullptr`. `system_error` with an error condition of `resource_deadlock_would_occur` if on entry `owns` is `true`.

```
template <class Clock, class Duration>
  bool
  try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
```

8 *Effects:* `pm->try_lock_shared_until(abs_time)`.

9 *Returns:* The value returned by the call to `pm->try_lock_shared_until(abs_time)`.

10 *Postconditions:* `owns == res`, where `res` is the value returned by the call to `pm->try_lock_shared_until(abs_time)`.

11 *Throws:* Any exception thrown by `pm->try_lock_shared_until(abs_time)`. `system_error` if an exception is required (30.3.2). `system_error` with an error condition of `operation_not_permitted` if `pm` is `nullptr`. `system_error` with an error condition of `resource_deadlock_would_occur` if on entry `owns` is `true`.

```
template <class Rep, class Period>
  bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
```

12 *Effects:* `pm->try_lock_shared_for(rel_time)`.

13 *Returns:* The value returned by the call to `pm->try_lock_shared_for(rel_time)`.

14 *Postconditions:* `owns == res`, where `res` is the value returned by the call to `pm->try_lock_shared_for(rel_time)`.

15 *Throws:* Any exception thrown by `pm->try_lock_shared_for(rel_time)`. `system_error` if an exception is required (30.3.2). `system_error` with an error condition of `operation_not_permitted` if `pm` is `nullptr`. `system_error` with an error condition of `resource_deadlock_would_occur` if on entry `owns` is `true`.

```
void unlock();
```

16 *Effects:* `pm->unlock_shared()`.

17 *Postconditions:* `owns == false`.

18 *Throws:* `system_error` when an exception is required (30.3.2).

19 *Error conditions:*

(19.1) — `operation_not_permitted` — if on entry `owns` is `false`.

30.146.0.1.3 `shared_lock` modifiers [thread.lock.shared.mod]

```
void swap(shared_lock& sl) noexcept;
```

1 *Effects:* Swaps the data members of `*this` and `sl`.

```
mutex_type* release() noexcept;
```

2 *Returns:* The previous value of `pm`.

3 *Postconditions:* `pm == nullptr` and `owns == false`.

```
template <class Mutex>
  void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
```

4 *Effects:* `x.swap(y)`.

30.146.0.1.4 `shared_lock` observers [thread.lock.shared.obs]

```
bool owns_lock() const noexcept;
```

1 *Returns:* `owns`.

```
explicit operator bool () const noexcept;
```

2 *Returns:* `owns`.

```
mutex_type* mutex() const noexcept;
```

3 *Returns:* `pm`.

30.146.1 Generic locking algorithms [thread.lock.algorithm]

```
template <class L1, class L2, class... L3> int try_lock(L1&, L2&, L3&...);
```

1

Requires: Each template parameter type shall meet the `Lockable` requirements. [*Note:* The `unique_lock` class template meets these requirements when suitably instantiated. — *end note*]

1 *Effects:* Calls `try_lock()` for each argument in order beginning with the first until all arguments have been processed or a call to `try_lock()` fails, either by returning `false` or by throwing an exception. If a call to `try_lock()` fails, `unlock()` shall be called for all prior arguments and there shall be no further calls to `try_lock()`.

2 *Returns:* `-1` if all calls to `try_lock()` returned `true`, otherwise a 0-based index value that indicates the argument for which `try_lock()` returned `false`.

```
template <class L1, class L2, class... L3> void lock(L1&, L2&, L3&...);
```

3 *Requires:* Each template parameter type shall meet the `Lockable` requirements, [*Note:* The `unique_lock` class template meets these requirements when suitably instantiated. — *end note*]

4

Effects: All arguments are locked via a sequence of calls to `lock()`, `try_lock()`, or `unlock()` on each argument. The sequence of calls shall not result in deadlock, but is otherwise unspecified. [*Note:* A deadlock avoidance algorithm such as try-and-back-off must be used, but the specific algorithm is not specified to avoid over-constraining implementations. — *end note*] If a call to `lock()` or `try_lock()` throws an exception, `unlock()` shall be called for any argument that had been locked by a call to `lock()` or `try_lock()`.

30.150.1 Call once [thread.once]

The class `once_flag` is an opaque data structure that `call_once` uses to initialize data without causing a data race or deadlock.

30.150.1.1 Struct `once_flag` [thread.once.onceflag]

```
constexpr once_flag() noexcept;
```

1 *Effects:* Constructs an object of type `once_flag`.

2 *Synchronization:* The construction of a `once_flag` object is not synchronized.

3 *Postcondition:* The object's internal state is set to indicate to an invocation of `call_once` with the object as its initial argument that no function has been called.

30.150.1.2 Function `call_once` [thread.once.callonce]

```
template<class Callable, class ...Args>
  void call_once(once_flag& flag, Callable&& func, Args&&... args);
```

1 *Requires:* `Callable` and each `Ti` in `Args` shall satisfy the `MoveConstructible` requirements. *`INVOKE`*`(`*`DECAY_COPY`*`( std::forward<Callable>(func)), `*`DECAY_COPY`*`(std::forward<Args>(args))...)` (20.295.1) shall be a valid expression.

2 *Effects:* An execution of `call_once` that does not call its `func` is a *passive* execution. An execution of `call_once` that calls its `func` is an *active* execution. An active execution shall call *`INVOKE`*`(`*`DECAY_COPY`*`( std::forward<Callable>(func)), `*`DECAY_COPY`*`(std::forward<Args>(args))...)`. If such a call to `func` throws an exception the execution is *exceptional*, otherwise it is *returning*. An exceptional execution shall propagate the exception to the caller of `call_once`. Among all executions of `call_once` for any given `once_flag`: at most one shall be a returning execution; if there is a returning execution, it shall be the last active execution; and there are passive executions only if there is a returning execution. [*Note:* passive executions allow other threads to reliably observe the results produced by the earlier returning execution. — *end note*]

1 *Synchronization:* For any given `once_flag`: all active executions occur in a total order; completion of an active execution synchronizes with (1.859) the start of the next one in this total order; and the returning execution synchronizes with the return from all passive executions.

1 *Throws:* `system_error` when an exception is required (30.3.2), or any exception thrown by `func`.

2 [*Example:*

```
// global flag, regular function
void init();
std::once_flag flag;

void f() {
  std::call_once(flag, init);
}

// function static flag, function object
struct initializer {
  void operator()();
};

void g() {
  static std::once_flag flag2;
  std::call_once(flag2, initializer());
}

// object flag, member function
class information {
  std::once_flag verified;
  void verifier();
public:
  void verify() { std::call_once(verified, &information::verifier, *this); }
};
```

— *end example*]

30.157 Condition variables [thread.condition]

1

Condition variables provide synchronization primitives used to block a thread until notified by some other thread that some condition is met or until a system time is reached. Class `condition_variable` provides a condition variable that can only wait on an object of type `unique_lock<mutex>`, allowing maximum efficiency on some platforms. Class `condition_variable_any` provides a general condition variable that can wait on objects of user-supplied lock types.

1 Condition variables permit concurrent invocation of the `wait`, `wait_for`, `wait_until`, `notify_one` and `notify_all` member functions.

2

The execution of `notify_one` and `notify_all` shall be atomic. The execution of `wait`, `wait_for`, and `wait_until` shall be performed in three atomic parts:

1. the release of the mutex and entry into the waiting state;
2. the unblocking of the wait; and
3. the reacquisition of the lock.

1 The implementation shall behave as if all executions of `notify_one`, `notify_all`, and each part of the `wait`, `wait_for`, and `wait_until` executions are executed in a single unspecified total order consistent with the "happens before" order.

2 Condition variable construction and destruction need not be synchronized.

Header `condition_variable` synopsis

```
namespace std {
  class condition_variable;
  class condition_variable_any;

  void notify_all_at_thread_exit(condition_variable& cond, unique_lock<mutex> lk);

  enum class cv_status { no_timeout, timeout };
}
```

```
void notify_all_at_thread_exit(condition_variable& cond, unique_lock<mutex> lk);
```

3 *Requires:* `lk` is locked by the calling thread and either

(3.1) — no other thread is waiting on `cond`, or

(3.2) — `lk.mutex()` returns the same value for each of the lock arguments supplied by all concurrently waiting (via `wait`, `wait_for`, or `wait_until`) threads.

4 *Effects:* transfers ownership of the lock associated with `lk` into internal storage and schedules `cond` to be notified when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed. This notification shall be as if

```
lk.unlock();
cond.notify_all();
```

5 *Synchronization:* The implied `lk.unlock()` call is sequenced after the destruction of all objects with thread storage duration associated with the current thread.

6 *Note:* The supplied lock will be held until the thread exits, and care must be taken to ensure that this does not cause deadlock due to lock ordering issues. After calling `notify_all_at_thread_exit`

it is recommended that the thread should be exited as soon as possible, and that no blocking or time-consuming tasks are run on that thread.

7

Note: It is the user's responsibility to ensure that waiting threads do not erroneously assume that the thread has finished if they experience spurious wakeups. This typically requires that the condition being waited for is satisfied while holding the lock on `lk`, and that this lock is not released and reacquired prior to calling `notify_all_at_thread_exit`.

30.161.1 Class `condition_variable` [thread.condition.condvar]

```
namespace std {
  class condition_variable {
  public:

    condition_variable();
    ~condition_variable();

    condition_variable(const condition_variable&) = delete;
    condition_variable& operator=(const condition_variable&) = delete;

    void notify_one() noexcept;
    void notify_all() noexcept;
    void wait(unique_lock<mutex>& lock);
    template <class Predicate>
      void wait(unique_lock<mutex>& lock, Predicate pred);
    template <class Clock, class Duration>
      cv_status wait_until(unique_lock<mutex>& lock,
                           const chrono::time_point<Clock, Duration>& abs_time);
    template <class Clock, class Duration, class Predicate>
      bool wait_until(unique_lock<mutex>& lock,
                      const chrono::time_point<Clock, Duration>& abs_time,
                      Predicate pred);

    template <class Rep, class Period>
      cv_status wait_for(unique_lock<mutex>& lock,
                         const chrono::duration<Rep, Period>& rel_time);
    template <class Rep, class Period, class Predicate>
      bool wait_for(unique_lock<mutex>& lock,
                    const chrono::duration<Rep, Period>& rel_time,
                    Predicate pred);

    typedef implementation-defined native_handle_type; // See 30.6.1
    native_handle_type native_handle();                // See 30.6.1
  };
}
```

1 The class `condition_variable` shall be a standard-layout class (Clause 9).

`condition_variable();`

2 *Effects:* Constructs an object of type `condition_variable`.

3 *Throws:* `system_error` when an exception is required (30.3.2).

4 *Error conditions:*

(4.1) — `resource_unavailable_try_again` — if some non-memory resource limitation prevents initialization.

```
~condition_variable();
```

5

Requires: There shall be no thread blocked on `*this`. [*Note:* That is, all threads shall have been notified; they may subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait must happen before destruction. The user must take care to ensure that no threads wait on `*this` once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of `wait`, `wait_for`, or `wait_until` that take a predicate. — *end note*]

1 *Effects:* Destroys the object.

```
void notify_one() noexcept;
```

2 *Effects:* If any threads are blocked waiting for `*this`, unblocks one of those threads.

```
void notify_all() noexcept;
```

1 *Effects:* Unblocks all threads that are blocked waiting for `*this`.

```
void wait(unique_lock<mutex>& lock);
```

1

Requires: `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread, and either

— no other thread is waiting on this `condition_variable` object or

— `lock.mutex()` returns the same value for each of the `lock` arguments supplied by all concurrently waiting (via `wait`, `wait_for`, or `wait_until`) threads.

1 *Effects:*

— Atomically calls `lock.unlock()` and blocks on `*this`.

— When unblocked, calls `lock.lock()` (possibly blocking on the lock), then returns.

— The function will unblock when signaled by a call to `notify_one()` or a call to `notify_all()`, or spuriously.

1 *Remarks:* If the function fails to meet the postcondition, `std::terminate()` shall be called (15.308.1). [*Note:* This can happen if the re-locking of the mutex throws an exception. — *end note*]

2 *Postcondition:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread.

3 *Throws:* Nothing.

```
template <class Predicate>
  void wait(unique_lock<mutex>& lock, Predicate pred);
```

4 *Requires:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread, and either

(4.1) — no other thread is waiting on this `condition_variable` object or

(4.2) — `lock.mutex()` returns the same value for each of the `lock` arguments supplied by all concurrently waiting (via `wait`, `wait_for`, or `wait_until`) threads.

5 *Effects:* Equivalent to:

```
while (!pred())
  wait(lock);
```

6 *Remarks:* If the function fails to meet the postcondition, `std::terminate()` shall be called (15.308.1). [*Note:* This can happen if the re-locking of the mutex throws an exception. — *end note*]

7 *Postcondition:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread.

8 *Throws:* Timeout-related exceptions (30.8.1) or any exception thrown by `pred`.

```
template <class Clock, class Duration>
  cv_status wait_until(unique_lock<mutex>& lock,
                       const chrono::time_point<Clock, Duration>& abs_time);
```

9 *Requires:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread, and either

(9.1) — no other thread is waiting on this `condition_variable` object or

(9.2) — `lock.mutex()` returns the same value for each of the `lock` arguments supplied by all concurrently waiting (via `wait`, `wait_for`, or `wait_until`) threads.

10

Effects:

— Atomically calls `lock.unlock()` and blocks on `*this`.

— When unblocked, calls `lock.lock()` (possibly blocking on the lock), then returns.

— The function will unblock when signaled by a call to `notify_one()`, a call to `notify_all()`, expiration of the absolute timeout (30.8.1) specified by `abs_time`, or spuriously.

— If the function exits via an exception, `lock.lock()` shall be called prior to exiting the function.

1 *Remarks:* If the function fails to meet the postcondition, `std::terminate()` shall be called (15.308.1). [*Note:* This can happen if the re-locking of the mutex throws an exception. — *end note*]

2 *Postcondition:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread.

3

Returns: `cv_status::timeout` if the absolute timeout (30.8.1) specified by `abs_time` expired, otherwise `cv_status::no_timeout`.

1 *Throws:* Timeout-related exceptions (30.8.1).

```
template <class Rep, class Period>
  cv_status wait_for(unique_lock<mutex>& lock,
                     const chrono::duration<Rep, Period>& rel_time);
```

2 *Requires:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread, and either

(2.1) — no other thread is waiting on this `condition_variable` object or

(2.2) — `lock.mutex()` returns the same value for each of the `lock` arguments supplied by all concurrently waiting (via `wait`, `wait_for`, or `wait_until`) threads.

3 *Effects:* Equivalent to:

```
return wait_until(lock, chrono::steady_clock::now() + rel_time);
```

4 *Returns:* `cv_status::timeout` if the relative timeout (30.8.1) specified by `rel_time` expired, otherwise `cv_status::no_timeout`.

5 *Remarks:* If the function fails to meet the postcondition, `std::terminate()` shall be called (15.308.1). [*Note:* This can happen if the re-locking of the mutex throws an exception. — *end note*]

6 *Postcondition:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread.

7 *Throws:* Timeout-related exceptions (30.8.1).

```
template <class Clock, class Duration, class Predicate>
  bool wait_until(unique_lock<mutex>& lock,
                  const chrono::time_point<Clock, Duration>& abs_time,
                  Predicate pred);
```

8 *Requires:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread, and either

(8.1) — no other thread is waiting on this `condition_variable` object or

(8.2) — `lock.mutex()` returns the same value for each of the `lock` arguments supplied by all concurrently waiting (via `wait`, `wait_for`, or `wait_until`) threads.

9 *Effects:* Equivalent to:

```
while (!pred())
  if (wait_until(lock, abs_time) == cv_status::timeout)
    return pred();
return true;
```

10 *Remarks:* If the function fails to meet the postcondition, `std::terminate()` shall be called (15.308.1). [*Note:* This can happen if the re-locking of the mutex throws an exception. — *end note*]

11 *Postcondition:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread.

12 [*Note:* The returned value indicates whether the predicate evaluated to `true` regardless of whether the timeout was triggered. — *end note*]

13 *Throws:* Timeout-related exceptions (30.8.1) or any exception thrown by `pred`.

```
template <class Rep, class Period, class Predicate>
  bool wait_for(unique_lock<mutex>& lock,
                const chrono::duration<Rep, Period>& rel_time,
                Predicate pred);
```

14 *Requires:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread, and either

(14.1) — no other thread is waiting on this `condition_variable` object or

(14.2) — `lock.mutex()` returns the same value for each of the `lock` arguments supplied by all concurrently waiting (via `wait`, `wait_for`, or `wait_until`) threads.

15 *Effects:* Equivalent to:

```
return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));
```

16 [*Note:* There is no blocking if `pred()` is initially `true`, even if the timeout has already expired. — *end note*]

17 *Remarks:* If the function fails to meet the postcondition, `std::terminate()` shall be called (15.308.1). [*Note:* This can happen if the re-locking of the mutex throws an exception. — *end note*]

18 *Postcondition:* `lock.owns_lock()` is `true` and `lock.mutex()` is locked by the calling thread.

19 [*Note:* The returned value indicates whether the predicate evaluates to `true` regardless of whether the timeout was triggered. — *end note*]

20 *Throws:* Timeout-related exceptions (30.8.1) or any exception thrown by `pred`.

30.177.1 Class `condition_variable_any` [thread.condition.condvarany]

1

A `Lock` type shall meet the `BasicLockable` requirements (30.17.0.1). [*Note:* All of the standard mutex types meet this requirement. If a `Lock` type other than one of the standard mutex types or a `unique_lock` wrapper for a standard mutex type is used with `condition_variable_any`, the user must ensure that any necessary synchronization is in place with respect to the predicate associated with the `condition_variable_any` instance. — *end note*]

```
namespace std {
  class condition_variable_any {
  public:
    condition_variable_any();
    ~condition_variable_any();

    condition_variable_any(const condition_variable_any&) = delete;
    condition_variable_any& operator=(const condition_variable_any&) = delete;

    void notify_one() noexcept;
    void notify_all() noexcept;
    template <class Lock>
      void wait(Lock& lock);
    template <class Lock, class Predicate>
      void wait(Lock& lock, Predicate pred);

    template <class Lock, class Clock, class Duration>
      cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);
    template <class Lock, class Clock, class Duration, class Predicate>
      bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time,
        Predicate pred);
    template <class Lock, class Rep, class Period>
      cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);
    template <class Lock, class Rep, class Period, class Predicate>
      bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time,
        Predicate pred);
  };
}
```

`condition_variable_any();`

1 *Effects:* Constructs an object of type `condition_variable_any`.

2 *Throws:* `bad_alloc` or `system_error` when an exception is required (30.3.2).

3 *Error conditions:*

(3.1) — `resource_unavailable_try_again` — if some non-memory resource limitation prevents initialization.

(3.2) — `operation_not_permitted` — if the thread does not have the privilege to perform the operation.

`~condition_variable_any();`

4 *Requires:* There shall be no thread blocked on `*this`. [*Note:* That is, all threads shall have been notified; they may subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait must happen before destruction. The user must take care to ensure that no threads wait on

`*this` once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of `wait`, `wait_for`, or `wait_until` that take a predicate. — *end note*]

5 *Effects:* Destroys the object.

```
void notify_one() noexcept;
```

6 *Effects:* If any threads are blocked waiting for `*this`, unblocks one of those threads.

```
void notify_all() noexcept;
```

7 *Effects:* Unblocks all threads that are blocked waiting for `*this`.

```
template <class Lock>
  void wait(Lock& lock);
```

8 *Note:* if any of the `wait` functions exits via an exception, it is unspecified whether the `Lock` is held. One can use a `Lock` type that allows to query that, such as the `unique_lock` wrapper.

9 *Effects:*

(9.1) — Atomically calls `lock.unlock()` and blocks on `*this`.

(9.2) — When unblocked, calls `lock.lock()` (possibly blocking on the lock) and returns.

(9.3) — The function will unblock when signaled by a call to `notify_one()`, a call to `notify_all()`, or spuriously.

10 *Remarks:* If the function fails to meet the postcondition, `std::terminate()` shall be called (15.308.1). [*Note:* This can happen if the re-locking of the mutex throws an exception. — *end note*]

11 *Postcondition:* `lock` is locked by the calling thread.

12 *Throws:* Nothing.

```
template <class Lock, class Predicate>
  void wait(Lock& lock, Predicate pred);
```

13 *Effects:* Equivalent to:

```
while (!pred())
  wait(lock);
```

```
template <class Lock, class Clock, class Duration>
  cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);
```

14 *Effects:*

(14.1) — Atomically calls `lock.unlock()` and blocks on `*this`.

(14.2) — When unblocked, calls `lock.lock()` (possibly blocking on the lock) and returns.

(14.3) — The function will unblock when signaled by a call to `notify_one()`, a call to `notify_all()`, expiration of the absolute timeout (30.8.1) specified by `abs_time`, or spuriously.

(14.4) — If the function exits via an exception, `lock.lock()` shall be called prior to exiting the function.

15 *Remarks:* If the function fails to meet the postcondition, `std::terminate()` shall be called (15.308.1). [*Note:* This can happen if the re-locking of the mutex throws an exception. — *end note*]

16 *Postcondition:* `lock` is locked by the calling thread.

17 *Returns:* `cv_status::timeout` if the absolute timeout (30.8.1) specified by `abs_time` expired, otherwise `cv_status::no_timeout`.

18 *Throws:* Timeout-related exceptions (30.8.1).

```
template <class Lock, class Rep, class Period>
  cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);
```

19 *Effects:* Equivalent to:

```
return wait_until(lock, chrono::steady_clock::now() + rel_time);
```

20 *Returns:* `cv_status::timeout` if the relative timeout (30.8.1) specified by `rel_time` expired, otherwise `cv_status::no_timeout`.

21 *Remarks:* If the function fails to meet the postcondition, `std::terminate()` shall be called (15.308.1). [*Note:* This can happen if the re-locking of the mutex throws an exception. — *end note*]

22 *Postcondition:* `lock` is locked by the calling thread.

23 *Throws:* Timeout-related exceptions (30.8.1).

```
template <class Lock, class Clock, class Duration, class Predicate>
  bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time, Predicate pred);
```

24 *Effects:* Equivalent to:

```
while (!pred())
  if (wait_until(lock, abs_time) == cv_status::timeout)
    return pred();
return true;
```

25 [*Note:* There is no blocking if `pred()` is initially `true`, or if the timeout has already expired. — *end note*]

26 [*Note:* The returned value indicates whether the predicate evaluates to `true` regardless of whether the timeout was triggered. — *end note*]

```
template <class Lock, class Rep, class Period, class Predicate>
  bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time, Predicate pred);
```

27 *Effects:* Equivalent to:

```
return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));
```

30.179 Futures [futures]

30.179.1 Overview [futures.overview]

1 30.179 describes components that a C++ program can use to retrieve in one thread the result (value or exception) from a function that has run in the same thread or another thread. [*Note:* These components are not restricted to multi-threaded programs but can be useful in single-threaded programs as well. — *end note*]

Header `<future>` synopsis

```
namespace std {
  enum class future_errc {
    broken_promise = implementation-defined,
    future_already_retrieved = implementation-defined,
    promise_already_satisfied = implementation-defined,
    no_state = implementation-defined
  };

  enum class launch : unspecified {
    async = unspecified,
```

```
    deferred = unspecified,
    implementation-defined
  };

  enum class future_status {
    ready,
    timeout,
    deferred
  };

  template <> struct is_error_code_enum<future_errc> : public true_type { };
  error_code make_error_code(future_errc e) noexcept;
  error_condition make_error_condition(future_errc e) noexcept;

  const error_category& future_category() noexcept;

  class future_error;

  template <class R> class promise;
  template <class R> class promise<R&>;
  template <> class promise<void>;

  template <class R>
    void swap(promise<R>& x, promise<R>& y) noexcept;

  template <class R, class Alloc>
    struct uses_allocator<promise<R>, Alloc>;

  template <class R> class future;
  template <class R> class future<R&>;
  template <> class future<void>;

  template <class R> class shared_future;
  template <class R> class shared_future<R&>;
  template <> class shared_future<void>;

  template <class> class packaged_task;   // undefined
  template <class R, class... ArgTypes>
    class packaged_task<R(ArgTypes...)>;

  template <class R, class... ArgTypes>
    void swap(packaged_task<R(ArgTypes...)>&, packaged_task<R(ArgTypes...)>&) noexcept;

  template <class R, class Alloc>
    struct uses_allocator<packaged_task<R>, Alloc>;

  template <class F, class... Args>
    future<result_of_t<decay_t<F>(decay_t<Args>...)>>
    async(F&& f, Args&&... args);
  template <class F, class... Args>
    future<result_of_t<decay_t<F>(decay_t<Args>...)>>
    async(launch policy, F&& f, Args&&... args);
}
```

2 The `enum` type `launch` is a bitmask type (17.20.0.0.1) with `launch::async` and `launch::deferred` denoting

individual bits. [*Note:* Implementations can provide bitmasks to specify restrictions on task interaction by functions launched by `async()` applicable to a corresponding subset of available launch policies. Implementations can extend the behavior of the first overload of `async()` by adding their extensions to the launch policy under the "as if" rule. — *end note*]

3 The enum values of `future_errc` are distinct and not zero.

30.179.2 Error handling [futures.errors]

```
const error_category& future_category() noexcept;
```

1 *Returns:* A reference to an object of a type derived from class `error_category`.

2 The object's `default_error_condition` and equivalent virtual functions shall behave as specified for the class `error_category`. The object's `name` virtual function shall return a pointer to the string `"future"`.

```
error_code make_error_code(future_errc e) noexcept;
```

3 *Returns:* `error_code(static_cast<int>(e), future_category())`.

```
error_condition make_error_condition(future_errc e) noexcept;
```

4 *Returns:* `error_condition(static_cast<int>(e), future_category())`.

30.179.3 Class `future_error` [futures.future_error]

```
namespace std {
  class future_error : public logic_error {
  public:
    future_error(error_code ec);  // exposition only

    const error_code& code() const noexcept;
    const char*       what() const noexcept;
  };
}
```

```
const error_code& code() const noexcept;
```

1 *Returns:* The value of `ec` that was passed to the object's constructor.

```
const char* what() const noexcept;
```

2 *Returns:* An NTBS incorporating `code().message()`.

30.179.4 Shared state [futures.state]

1

Many of the classes introduced in this sub-clause use some state to communicate results. This *shared state* consists of some state information and some (possibly not yet evaluated) *result*, which can be a (possibly void) value or an exception. [*Note:* Futures, promises, and tasks defined in this clause reference such shared state. — *end note*]

1

[*Note:* The result can be any kind of object including a function to compute that result, as used by `async` when `policy` is `launch::deferred`. — *end note*]

1 An *asynchronous return object* is an object that reads results from a shared state. A *waiting function* of an asynchronous return object is one that potentially blocks to wait for the shared state to be made ready. If a

waiting function can return before the state is made ready because of a timeout (30.16.1), then it is a *timed waiting function*, otherwise it is a *non-timed waiting function*.

2 An *asynchronous provider* is an object that provides a result to a shared state. The result of a shared state is set by respective functions on the asynchronous provider. [*Note:* Such as promises or tasks. — *end note*] The means of setting the result of a shared state is specified in the description of those classes and functions that create such a state object.

3

When an asynchronous return object or an asynchronous provider is said to release its shared state, it means:

— if the return object or provider holds the last reference to its shared state, the shared state is destroyed; and

— the return object or provider gives up its reference to its shared state; and

— these actions will not block for the shared state to become ready, except that it may block if all of the following are true: the shared state was created by a call to `std::async`, the shared state is not yet ready, and this was the last reference to the shared state.

1 When an asynchronous provider is said to make its shared state ready, it means:

(1.1) — first, the provider marks its shared state as ready; and

(1.2) — second, the provider unblocks any execution agents waiting for its shared state to become ready.

2 When an asynchronous provider is said to abandon its shared state, it means:

(2.1) — first, if that state is not ready, the provider

(2.1.1) — stores an exception object of type `future_error` with an error condition of `broken_promise` within its shared state; and then

(2.1.2) — makes its shared state ready;

(2.2) — second, the provider releases its shared state.

3 A shared state is *ready* only if it holds a value or an exception ready for retrieval. Waiting for a shared state to become ready may invoke code to compute the result on the waiting thread if so specified in the description of the class or function that creates the state object.

4

Calls to functions that successfully set the stored result of a shared state synchronize with (1.859) calls to functions successfully detecting the ready state resulting from that setting. The storage of the result (whether normal or exceptional) into the shared state synchronizes with (1.859) the successful return from a call to a waiting function on the shared state.

1 Some functions (e.g., `promise::set_value_at_thread_exit`) delay making the shared state ready until the calling thread exits. The destruction of each of that thread's objects with thread storage duration (3.2291.1) is sequenced before making that shared state ready.

2 Access to the result of the same shared state may conflict (1.859). [*Note:* this explicitly specifies that the result of the shared state is visible in the objects that reference this state in the sense of data race avoidance (17.607.0.1). For example, concurrent accesses through references returned by `shared_future::get()` (30.203.1) must either use read-only operations or provide additional synchronization. — *end note*]

30.191.1 Class template promise [futures.promise]

```
namespace std {
  template <class R>
  class promise {
  public:
    promise();
    template <class Allocator>
      promise(allocator_arg_t, const Allocator& a);
    promise(promise&& rhs) noexcept;
    promise(const promise& rhs) = delete;
    ~promise();

    // assignment
    promise& operator=(promise&& rhs) noexcept;
    promise& operator=(const promise& rhs) = delete;
    void swap(promise& other) noexcept;

    // retrieving the result
    future<R> get_future();

    // setting the result
    void set_value(see below);
    void set_exception(exception_ptr p);

    // setting the result with deferred notification
    void set_value_at_thread_exit(const R& r);
    void set_value_at_thread_exit(see below);
    void set_exception_at_thread_exit(exception_ptr p);
  };
  template <class R>
    void swap(promise<R>& x, promise<R>& y) noexcept;
  template <class R, class Alloc>
    struct uses_allocator<promise<R>, Alloc>;
}
```

1 The implementation shall provide the template `promise` and two specializations, `promise<R&>` and `promise<void>`. These differ only in the argument type of the member function `set_value`, as set out in its description, below.

2 The `set_value`, `set_exception`, `set_value_at_thread_exit`, and `set_exception_at_thread_exit` member functions behave as though they acquire a single mutex associated with the promise object while updating the promise object.

```
template <class R, class Alloc>
  struct uses_allocator<promise<R>, Alloc>
    : true_type { };
```

1 *Requires:* `Alloc` shall be an Allocator (17.165.0.1).

```
promise();
template <class Allocator>
  promise(allocator_arg_t, const Allocator& a);
```

2

Effects: constructs a `promise` object and a shared state. The second constructor uses the allocator `a` to allocate memory for the shared state.

```
promise(promise&& rhs) noexcept;
```

1 *Effects:* constructs a new `promise` object and transfers ownership of the shared state of `rhs` (if any) to the newly-constructed object.

2 *Postcondition:* `rhs` has no shared state.

```
~promise();
```

3 *Effects:* Abandons any shared state (30.179.4).

```
promise& operator=(promise&& rhs) noexcept;
```

4 *Effects:* Abandons any shared state (30.179.4) and then as if `promise(std::move(rhs)).swap(*this)`.

5 *Returns:* `*this`.

```
void swap(promise& other) noexcept;
```

6 *Effects:* Exchanges the shared state of `*this` and `other`.

7 *Postcondition:* `*this` has the shared state (if any) that `other` had prior to the call to `swap`. `other` has the shared state (if any) that `*this` had prior to the call to `swap`.

```
future<R> get_future();
```

8 *Returns:* A `future<R>` object with the same shared state as `*this`.

9 *Throws:* `future_error` if `*this` has no shared state or if `get_future` has already been called on a `promise` with the same shared state as `*this`.

10 *Error conditions:*

(10.1) — `future_already_retrieved` if `get_future` has already been called on a `promise` with the same shared state as `*this`.

(10.2) — `no_state` if `*this` has no shared state.

```
void promise::set_value(const R& r);
void promise::set_value(R&& r);
void promise<R&>::set_value(R& r);
void promise<void>::set_value();
```

11 *Effects:* atomically stores the value `r` in the shared state and makes that state ready (30.179.4).

12 *Throws:*

(12.1) — `future_error` if its shared state already has a stored value or exception, or

(12.2) — for the first version, any exception thrown by the constructor selected to copy an object of `R`, or

(12.3) — for the second version, any exception thrown by the constructor selected to move an object of `R`.

13 *Error conditions:*

(13.1) — `promise_already_satisfied` if its shared state already has a stored value or exception.

(13.2) — `no_state` if `*this` has no shared state.

```
void set_exception(exception_ptr p);
```

14 *Effects:* atomically stores the exception pointer `p` in the shared state and makes that state ready (30.179.4).

15 *Throws:* `future_error` if its shared state already has a stored value or exception.

16 *Error conditions:*

(16.1) — `promise_already_satisfied` if its shared state already has a stored value or exception.

(16.2) — `no_state` if `*this` has no shared state.

```
void promise::set_value_at_thread_exit(const R& r);
void promise::set_value_at_thread_exit(R&& r);
void promise<R&>::set_value_at_thread_exit(R& r);
void promise<void>::set_value_at_thread_exit();
```

17 *Effects:* Stores the value `r` in the shared state without making that state ready immediately. Schedules that state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

18 *Throws:*

(18.1) — `future_error` if its shared state already has a stored value or exception, or

(18.2) — for the first version, any exception thrown by the constructor selected to copy an object of `R`, or

(18.3) — for the second version, any exception thrown by the constructor selected to move an object of `R`.

19 *Error conditions:*

(19.1) — `promise_already_satisfied` if its shared state already has a stored value or exception.

(19.2) — `no_state` if `*this` has no shared state.

```
void set_exception_at_thread_exit(exception_ptr p);
```

20 *Effects:* Stores the exception pointer `p` in the shared state without making that state ready immediately. Schedules that state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

21 *Throws:* `future_error` if an error condition occurs.

22 *Error conditions:*

(22.1) — `promise_already_satisfied` if its shared state already has a stored value or exception.

(22.2) — `no_state` if `*this` has no shared state.

```
template <class R>
  void swap(promise<R>& x, promise<R>& y);
```

23 *Effects:* `x.swap(y)`.

30.194.1 Class template `future` [futures.unique_future]

1 The class template `future` defines a type for asynchronous return objects which do not share their shared state with other asynchronous return objects. A default-constructed `future` object has no shared state. A `future` object with shared state can be created by functions on asynchronous providers (30.179.4) or by the move constructor and shares its shared state with the original asynchronous provider. The result (value or exception) of a `future` object can be set by calling a respective function on an object that shares the same shared state.

2 [*Note:* Member functions of `future` do not synchronize with themselves or with member functions of `shared_future`. — *end note*]

3

The effect of calling any member function other than the destructor, the move-assignment operator, or `valid` on a `future` object for which `valid() == false` is undefined. [*Note:* Implementations are encouraged to detect this case and throw an object of type `future_error` with an error condition of `future_errc::no_state`. — *end note*]

```
namespace std {
  template <class R>
  class future {
  public:
    future() noexcept;
    future(future &&) noexcept;
    future(const future& rhs) = delete;
    ~future();
    future& operator=(const future& rhs) = delete;
    future& operator=(future&&) noexcept;
    shared_future<R> share();

    // retrieving the value
    see below get();

    // functions to check state
    bool valid() const noexcept;

    void wait() const;
    template <class Rep, class Period>
      future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
    template <class Clock, class Duration>
      future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
  };
}
```

1 The implementation shall provide the template `future` and two specializations, `future<R&>` and `future<void>`. These differ only in the return type and return value of the member function `get`, as set out in its description, below.

`future() noexcept;`

2 *Effects:* constructs an *empty* `future` object that does not refer to a shared state.

3 *Postcondition:* `valid() == false`.

`future(future&& rhs) noexcept;`

4 *Effects:* move constructs a `future` object that refers to the shared state that was originally referred to by `rhs` (if any).

5 *Postconditions:*

(5.1) — `valid()` returns the same value as `rhs.valid()` prior to the constructor invocation.

(5.2) — `rhs.valid() == false`.

`~future();`

6

Effects:

— releases any shared state (30.179.4);

— destroys `*this`.

```
future& operator=(future&& rhs) noexcept;
```

1

Effects:

— releases any shared state (30.179.4).

— move assigns the contents of `rhs` to `*this`.

1 *Postconditions:*

(1.1) — `valid()` returns the same value as `rhs.valid()` prior to the assignment.

(1.2) — `rhs.valid() == false`.

```
shared_future<R> share();
```

2 *Returns:* `shared_future<R>(std::move(*this))`.

3 *Postcondition:* `valid() == false`.

```
R future::get();
R& future<R&>::get();
void future<void>::get();
```

4 *Note:* as described above, the template and its two required specializations differ only in the return type and return value of the member function `get`.

5 *Effects:* `wait()`s until the shared state is ready, then retrieves the value stored in the shared state.

6 *Returns:*

(6.1) — `future::get()` returns the value `v` stored in the object's shared state as `std::move(v)`.

(6.2) — `future<R&>::get()` returns the reference stored as value in the object's shared state.

(6.3) — `future<void>::get()` returns nothing.

7

Throws: the stored exception, if an exception was stored in the shared state.

1

Postcondition: `valid() == false`.

```
bool valid() const noexcept;
```

1

Returns: `true` only if `*this` refers to a shared state.

```
void wait() const;
```

1 *Effects:* blocks until the shared state is ready.

```
template <class Rep, class Period>
  future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
```

2 *Effects:* none if the shared state contains a deferred function (30.207.1), otherwise blocks until the shared state is ready or until the relative timeout (30.8.1) specified by `rel_time` has expired.

3 *Returns:*

(3.1) — `future_status::deferred` if the shared state contains a deferred function.

(3.2) — `future_status::ready` if the shared state is ready.

(3.3) — `future_status::timeout` if the function is returning because the relative timeout (30.8.1) specified by `rel_time` has expired.

4 *Throws:* timeout-related exceptions (30.8.1).

```
template <class Clock, class Duration>
  future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
```

5 *Effects:* none if the shared state contains a deferred function (30.207.1), otherwise blocks until the shared state is ready or until the absolute timeout (30.8.1) specified by `abs_time` has expired.

6 *Returns:*

(6.1) — `future_status::deferred` if the shared state contains a deferred function.

(6.2) — `future_status::ready` if the shared state is ready.

(6.3) — `future_status::timeout` if the function is returning because the absolute timeout (30.8.1) specified by `abs_time` has expired.

7 *Throws:* timeout-related exceptions (30.8.1).

30.203.1 Class template `shared_future` [futures.shared_future]

1 The class template `shared_future` defines a type for asynchronous return objects which may share their shared state with other asynchronous return objects. A default-constructed `shared_future` object has no shared state. A `shared_future` object with shared state can be created by conversion from a `future` object and shares its shared state with the original asynchronous provider (30.179.4) of the shared state. The result (value or exception) of a `shared_future` object can be set by calling a respective function on an object that shares the same shared state.

2

[*Note:* Member functions of `shared_future` do not synchronize with themselves, but they synchronize with the shared shared state. — *end note*]

1 The effect of calling any member function other than the destructor, the move-assignment operator, or `valid()` on a `shared_future` object for which `valid() == false` is undefined. [*Note:* Implementations are encouraged to detect this case and throw an object of type `future_error` with an error condition of `future_errc::no_state`. — *end note*]

```
namespace std {
  template <class R>
  class shared_future {
  public:
    shared_future() noexcept;
    shared_future(const shared_future& rhs);
    shared_future(future<R>&&) noexcept;
    shared_future(shared_future&& rhs) noexcept;
    ~shared_future();
    shared_future& operator=(const shared_future& rhs);
    shared_future& operator=(shared_future&& rhs) noexcept;

    // retrieving the value
    see below get() const;

    // functions to check state
    bool valid() const noexcept;
```

```
    void wait() const;
    template <class Rep, class Period>
      future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
    template <class Clock, class Duration>
      future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
  };
}
```

2 The implementation shall provide the template `shared_future` and two specializations, `shared_future<R&>` and `shared_future<void>`. These differ only in the return type and return value of the member function `get`, as set out in its description, below.

`shared_future() noexcept;`

3 *Effects:* constructs an *empty* `shared_future` object that does not refer to a shared state.

4 *Postcondition:* `valid() == false`.

`shared_future(const shared_future& rhs);`

5 *Effects:* constructs a `shared_future` object that refers to the same shared state as `rhs` (if any).

6 *Postcondition:* `valid()` returns the same value as `rhs.valid()`.

```
shared_future(future<R>&& rhs) noexcept;
shared_future(shared_future&& rhs) noexcept;
```

7 *Effects:* move constructs a `shared_future` object that refers to the shared state that was originally referred to by `rhs` (if any).

8 *Postconditions:*

(8.1) — `valid()` returns the same value as `rhs.valid()` returned prior to the constructor invocation.

(8.2) — `rhs.valid() == false`.

`~shared_future();`

9

Effects:

— releases any shared state (30.179.4);

— destroys `*this`.

`shared_future& operator=(shared_future&& rhs) noexcept;`

1 *Effects:*

(1.1) — releases any shared state (30.179.4);

(1.2) — move assigns the contents of `rhs` to `*this`.

2 *Postconditions:*

(2.1) — `valid()` returns the same value as `rhs.valid()` returned prior to the assignment.

(2.2) — `rhs.valid() == false`.

`shared_future& operator=(const shared_future& rhs);`

3 *Effects:*

(3.1) — releases any shared state (30.179.4);

(3.2) — assigns the contents of `rhs` to `*this`. [*Note:* As a result, `*this` refers to the same shared state as `rhs` (if any). — *end note*]

4 *Postconditions:* `valid() == rhs.valid()`.

```
const R& shared_future::get() const;
R& shared_future<R&>::get() const;
void shared_future<void>::get() const;
```

5 *Note:* as described above, the template and its two required specializations differ only in the return type and return value of the member function `get`.

6

Note: access to a value object stored in the shared state is unsynchronized, so programmers should apply only those operations on `R` that do not introduce a data race (1.859).

1 *Effects:* `wait()`s until the shared state is ready, then retrieves the value stored in the shared state.

2 *Returns:*

(2.1) — `shared_future::get()` returns a const reference to the value stored in the object's shared state. [*Note:* Access through that reference after the shared state has been destroyed produces undefined behavior; this can be avoided by not storing the reference in any storage with a greater lifetime than the `shared_future` object that returned the reference. — *end note*]

(2.2) — `shared_future<R&>::get()` returns the reference stored as value in the object's shared state.

(2.3) — `shared_future<void>::get()` returns nothing.

3 *Throws:* the stored exception, if an exception was stored in the shared state.

```
bool valid() const noexcept;
```

4 *Returns:* `true` only if `*this` refers to a shared state.

```
void wait() const;
```

5 *Effects:* blocks until the shared state is ready.

```
template <class Rep, class Period>
  future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
```

6 *Effects:* none if the shared state contains a deferred function (30.207.1), otherwise blocks until the shared state is ready or until the relative timeout (30.8.1) specified by `rel_time` has expired.

7 *Returns:*

(7.1) — `future_status::deferred` if the shared state contains a deferred function.

(7.2) — `future_status::ready` if the shared state is ready.

(7.3) — `future_status::timeout` if the function is returning because the relative timeout (30.8.1) specified by `rel_time` has expired.

8 *Throws:* timeout-related exceptions (30.8.1).

```
template <class Clock, class Duration>
  future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
```

9 *Effects:* none if the shared state contains a deferred function (30.207.1), otherwise blocks until the shared state is ready or until the absolute timeout (30.8.1) specified by `abs_time` has expired.

10 *Returns:*

(10.1) — `future_status::deferred` if the shared state contains a deferred function.

(10.2) — `future_status::ready` if the shared state is ready.

(10.3) — `future_status::timeout` if the function is returning because the absolute timeout (30.8.1) specified by `abs_time` has expired.

11 *Throws:* timeout-related exceptions (30.8.1).

30.207.1 Function template `async` [futures.async]

1

The function template `async` provides a mechanism to launch a function potentially in a new thread and provides the result of the function in a `future` object with which it shares a shared state.

```
template <class F, class... Args>
  future<result_of_t<decay_t<F>(decay_t<Args>...)>> async(F&& f, Args&&... args);
template <class F, class... Args>
  future<result_of_t<decay_t<F>(decay_t<Args>...)>> async(launch policy, F&& f, Args&&... args);
```

1 *Requires:* `F` and each `Ti` in `Args` shall satisfy the `MoveConstructible` requirements. *`INVOKE`*`(`*`DECAY_COPY`*`(std::forward<F>(f)), `*`DECAY_COPY`*`(std::forward<Args>(args))...)` (20.295.1, 30.31.0.1) shall be a valid expression.

2

Effects: The first function behaves the same as a call to the second function with a `policy` argument of `launch::async | launch::deferred` and the same arguments for `F` and `Args`. The second function creates a shared state that is associated with the returned `future` object. The further behavior of the second function depends on the `policy` argument as follows (if more than one of these conditions applies, the implementation may choose any of the corresponding policies):

— if `policy & launch::async` is non-zero — calls *`INVOKE`*`(`*`DECAY_COPY`*`(std::forward<F>(f)), `*`DECAY_COPY`*`(std::forward<Args>(args))...)` (20.295.1, 30.31.0.1) as if in a new thread of execution represented by a `thread` object with the calls to *`DECAY_COPY`*`()` being evaluated in the thread that called `async`. Any return value is stored as the result in the shared state. Any exception propagated from the execution of *`INVOKE`*`(`*`DECAY_COPY`*`(std::forward<F>(f)), `*`DECAY_COPY`*`(std::forward<Args>(args))...)` is stored as the exceptional result in the shared state. The `thread` object is stored in the shared state and affects the behavior of any asynchronous return objects that reference that state.

— if `policy & launch::deferred` is non-zero — Stores *`DECAY_COPY`*`(std::forward<F>(f))` and *`DECAY_COPY`*`(std::forward<Args>(args))...` in the shared state. These copies of `f` and `args` constitute a *deferred function*. Invocation of the deferred function evaluates *`INVOKE`*`(std::move(g), std::move(xyz))` where `g` is the stored value of *`DECAY_COPY`*`(std::forward<F>(f))` and `xyz` is the stored copy of *`DECAY_COPY`*`(std::forward<Args>(args))...`. Any return value is stored as the result in the shared state. Any exception propagated from the execution of the deferred function is stored as the exceptional result in the shared state. The shared state is not made ready until the function has completed. The first call to a non-timed waiting function (30.179.4) on an asynchronous return object referring to this shared state shall invoke the deferred function in the thread that called the waiting function. Once evaluation of *`INVOKE`*`(std::move(g), std::move(xyz))` begins, the function is no longer considered deferred. [*Note:* If this policy is specified together with other policies, such as when using a `policy` value of `launch::async | launch::deferred`, implementations should defer invocation or the selection of the policy when no more concurrency can be effectively exploited. — *end note*]

— If no value is set in the launch policy, or a value is set that is neither specified in this International Standard or by the implementation, the behaviour is undefined.

1

Returns: An object of type `future<result_of_t<decay_t<F>(decay_t<Args>...)>>` that refers to the shared state created by this call to `async`. [*Note:* If a future obtained from std::async is moved outside the local scope, other code that uses the future must be aware that the future's destructor may block for the shared state to become ready. — *end note*]

1

Synchronization: Regardless of the provided `policy` argument,

— the invocation of `async` synchronizes with (1.859) the invocation of `f`. [*Note:* This statement applies even when the corresponding `future` object is moved to another thread. — *end note*]; and

— the completion of the function `f` is sequenced before (1.859) the shared state is made ready. [*Note:* `f` might not be called at all, so its completion might never happen. — *end note*]

If the implementation chooses the `launch::async` policy,

— a call to a waiting function on an asynchronous return object that shares the shared state created by this `async` call shall block until the associated thread has completed, as if joined, or else time out (30.75.0.1);

— the associated thread completion synchronizes with (1.859) the return from the first function that successfully detects the ready status of the shared state or with the return from the last function that releases the shared state, whichever happens first.

1

Throws: `system_error` if `policy == launch::async` and the implementation is unable to start a new thread.

1

Error conditions:

— `resource_unavailable_try_again` — if `policy == launch::async` and the system is unable to start a new thread.

1 [*Example:*

```
int work1(int value);
int work2(int value);
int work(int value) {
  auto handle = std::async([=]{ return work2(value); });
  int tmp = work1(value);
  return tmp + handle.get();    // #1
}
```

[*Note:* Line #1 might not result in concurrency because the `async` call uses the default policy, which may use `launch::deferred`, in which case the lambda might not be invoked until the `get()` call; in that case, `work1` and `work2` are called on the same thread and there is no concurrency. — *end note*] — *end example*]

30.238.1 Class template packaged_task [futures.task]

1

The class template packaged_task defines a type for wrapping a function or callable object so that the return value of the function or callable object is stored in a future when it is invoked.

1 When the packaged_task object is invoked, its stored task is invoked and the result (whether normal or exceptional) stored in the shared state. Any futures that share the shared state will then be able to access the stored result.

```
namespace std {
  template<class> class packaged_task; // undefined

  template<class R, class... ArgTypes>
  class packaged_task<R(ArgTypes...)> {
  public:
    // construction and destruction
    packaged_task() noexcept;
    template <class F>
      explicit packaged_task(F&& f);
    template <class F, class Allocator>
      explicit packaged_task(allocator_arg_t, const Allocator& a, F&& f);
    ~packaged_task();

    // no copy
    packaged_task(const packaged_task&) = delete;
    packaged_task& operator=(const packaged_task&) = delete;

    // move support
    packaged_task(packaged_task&& rhs) noexcept;
    packaged_task& operator=(packaged_task&& rhs) noexcept;
    void swap(packaged_task& other) noexcept;

    bool valid() const noexcept;

    // result retrieval
    future<R> get_future();

    // execution
    void operator()(ArgTypes... );
    void make_ready_at_thread_exit(ArgTypes...);

    void reset();
  };
  template <class R, class... ArgTypes>
    void swap(packaged_task<R(ArgTypes...)>& x, packaged_task<R(ArgTypes...)>& y) noexcept;
  template <class R, class Alloc>
    struct uses_allocator<packaged_task<R>, Alloc>;
}
```

30.239.0.1 packaged_task member functions [futures.task.members]

```
packaged_task() noexcept;
```

1 *Effects:* constructs a packaged_task object with no shared state and no stored task.

```
template <class F>
```

```
  packaged_task(F&& f);
template <class F, class Allocator>
  explicit packaged_task(allocator_arg_t, const Allocator& a, F&& f);
```

2

Requires: `INVOKE(f, t1, t2, ..., tN, R)`, where `t1, t2, ..., tN` are values of the corresponding types in `ArgTypes...`, shall be a valid expression. Invoking a copy of `f` shall behave the same as invoking `f`.

1 *Remarks:* These constructors shall not participate in overload resolution if `decay_t<F>` is the same type as `std::packaged_task<R(ArgTypes...)>`.

2

Effects: constructs a new `packaged_task` object with a shared state and initializes the object's stored task with `std::forward<F>(f)`. The constructors that take an `Allocator` argument use it to allocate memory needed to store the internal data structures.

1

Throws: any exceptions thrown by the copy or move constructor of `f`, or `std::bad_alloc` if memory for the internal data structures could not be allocated.

```
packaged_task(packaged_task&& rhs) noexcept;
```

1 *Effects:* constructs a new `packaged_task` object and transfers ownership of `rhs`'s shared state to `*this`, leaving `rhs` with no shared state. Moves the stored task from `rhs` to `*this`.

2 *Postcondition:* `rhs` has no shared state.

```
packaged_task& operator=(packaged_task&& rhs) noexcept;
```

3 *Effects:*

(3.1) — releases any shared state (30.179.4).

(3.2) — `packaged_task(std::move(rhs)).swap(*this)`.

```
~packaged_task();
```

4 *Effects:* Abandons any shared state. (30.179.4).

```
void swap(packaged_task& other) noexcept;
```

5 *Effects:* exchanges the shared states and stored tasks of `*this` and `other`.

6 *Postcondition:* `*this` has the same shared state and stored task (if any) as `other` prior to the call to `swap`. `other` has the same shared state and stored task (if any) as `*this` prior to the call to `swap`.

```
bool valid() const noexcept;
```

7 *Returns:* `true` only if `*this` has a shared state.

```
future<R> get_future();
```

8 *Returns:* A `future` object that shares the same shared state as `*this`.

9 *Throws:* a `future_error` object if an error occurs.

10

Error conditions:

— `future_already_retrieved` if `get_future` has already been called on a `packaged_task` object with the same shared state as `*this`.

— `no_state` if `*this` has no shared state.

```
void operator()(ArgTypes... args);
```

1 *Effects:* *INVOKE*`(f, t1, t2, ..., tN, R)`, where `f` is the stored task of `*this` and `t1, t2, ..., tN` are the values in `args...`. If the task returns normally, the return value is stored as the asynchronous result in the shared state of `*this`, otherwise the exception thrown by the task is stored. The shared state of `*this` is made ready, and any threads blocked in a function waiting for the shared state of `*this` to become ready are unblocked.

2 *Throws:* a `future_error` exception object if there is no shared state or the stored task has already been invoked.

3 *Error conditions:*

(3.1) — `promise_already_satisfied` if the stored task has already been invoked.

(3.2) — `no_state` if `*this` has no shared state.

```
void make_ready_at_thread_exit(ArgTypes... args);
```

4 *Effects:* *INVOKE*`(f, t1, t2, ..., tN, R)`, where `f` is the stored task and `t1, t2, ..., tN` are the values in `args...`. If the task returns normally, the return value is stored as the asynchronous result in the shared state of `*this`, otherwise the exception thrown by the task is stored. In either case, this shall be done without making that state ready (30.179.4) immediately. Schedules the shared state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

5 *Throws:* `future_error` if an error condition occurs.

6 *Error conditions:*

(6.1) — `promise_already_satisfied` if the stored task has already been invoked.

(6.2) — `no_state` if `*this` has no shared state.

```
void reset();
```

7 *Effects:* as if `*this = packaged_task(std::move(f))`, where `f` is the task stored in `*this`. [*Note:* This constructs a new shared state for `*this`. The old state is abandoned (30.179.4). — *end note*]

1 *Throws:*

(1.1) — `bad_alloc` if memory for the new shared state could not be allocated.

(1.2) — any exception thrown by the move constructor of the task stored in the shared state.

(1.3) — `future_error` with an error condition of `no_state` if `*this` has no shared state.

30.247.0.1 `packaged_task` globals [futures.task.nonmembers]

```
template <class R, class... ArgTypes>
  void swap(packaged_task<R(ArgTypes...)>& x, packaged_task<R(ArgTypes...)>& y) noexcept;
```

1 *Effects:* `x.swap(y)`

```
template <class R, class Alloc>
  struct uses_allocator<packaged_task<R>, Alloc>
    : true_type { };
```

2 *Requires:* `Alloc` shall be an Allocator (17.165.0.1).

Annex A (informative) Grammar summary [gram]

1 This summary of C++ syntax is intended to be an aid to comprehension. It is not an exact statement of the language. In particular, the grammar described here accepts a superset of valid C++ constructs. Disambiguation rules (6.556, 7.40, 10.52) must be applied to distinguish expressions from declarations. Further, access control, ambiguity, and type rules must be used to weed out syntactically valid but meaningless constructs.

A.1 Keywords [gram.key]

1 New context-dependent keywords are introduced into a program by `typedef` (7.235.1), `namespace` (7.1149.1), class (Clause 9), enumeration (7.1001), and `template` (Clause 14) declarations.

typedef-name:
    identifier
namespace-name:
    original-namespace-name
    namespace-alias

original-namespace-name:
    identifier

namespace-alias:
    identifier

class-name:
    identifier
    simple-template-id
enum-name:
    identifier

template-name:
    identifier

Note that a *typedef-name* naming a class is also a *class-name* (9.172).

A.2 Lexical conventions [gram.lex]

hex-quad:
    hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit

universal-character-name:
    `\u` *hex-quad*
    `\U` *hex-quad hex-quad*

preprocessing-token:
    header-name
    identifier
    pp-number
    character-literal
    user-defined-character-literal
    string-literal
    user-defined-string-literal
    preprocessing-op-or-punc
    each non-white-space character that cannot be one of the above

token:
- *identifier*
- *keyword*
- *literal*
- *operator*
- *punctuator*

header-name:
- `<` *h-char-sequence* `>`
- `"` *q-char-sequence* `"`

h-char-sequence:
- *h-char*
- *h-char-sequence h-char*

h-char:
- any member of the source character set except new-line and `>`

q-char-sequence:
- *q-char*
- *q-char-sequence q-char*

q-char:
- any member of the source character set except new-line and `"`

pp-number:
- *digit*
- `.` *digit*
- *pp-number digit*
- *pp-number identifier-nondigit*
- *pp-number* `'` *digit*
- *pp-number* `'` *nondigit*
- *pp-number* `e` *sign*
- *pp-number* `E` *sign*
- *pp-number* `.`

identifier:
- *identifier-nondigit*
- *identifier identifier-nondigit*
- *identifier digit*

identifier-nondigit:
- *nondigit*
- *universal-character-name*
- other implementation-defined characters

nondigit: one of

```
a b c d e f g h i j k l m
n o p q r s t u v w x y z
A B C D E F G H I J K L M
N O P Q R S T U V W X Y Z _
```

digit: one of

```
0 1 2 3 4 5 6 7 8 9
```

preprocessing-op-or-punc: one of

```
{     }         [         ]         #         ##        (         )
<:    :>        <%        %>        %:        %:%:      ;         :         ...
new   delete    ?         ::        .         .*
+     -         *         /         %         ^         &         |         ~
!     =         <         >         +=        -=        *=        /=        %=
^=    &=        |=        <<        >>        >>=       <<=       ==        !=
<=    >=        &&        ||        ++        --        ,         ->*       ->
and   and_eq    bitand    bitor     compl     not       not_eq
or    or_eq     xor       xor_eq
```

literal:
- *integer-literal*
- *character-literal*
- *floating-literal*
- *string-literal*
- *boolean-literal*
- *pointer-literal*
- *user-defined-literal*

integer-literal:
- *decimal-literal integer-suffix*$_{opt}$
- *octal-literal integer-suffix*$_{opt}$
- *hexadecimal-literal integer-suffix*$_{opt}$
- *binary-literal integer-suffix*$_{opt}$

decimal-literal:
- *nonzero-digit*
- *decimal-literal* '$_{opt}$ *digit*

octal-literal:
- `0`
- *octal-literal* '$_{opt}$ *octal-digit*

hexadecimal-literal:
- `0x` *hexadecimal-digit*
- `0X` *hexadecimal-digit*
- *hexadecimal-literal* '$_{opt}$ *hexadecimal-digit*

binary-literal:
- `0b` *binary-digit*
- `0B` *binary-digit*
- *binary-literal* '$_{opt}$ *binary-digit*

nonzero-digit: one of
`1 2 3 4 5 6 7 8 9`

octal-digit: one of
`0 1 2 3 4 5 6 7`

hexadecimal-digit: one of
`0 1 2 3 4 5 6 7 8 9`
`a b c d e f`
`A B C D E F`

binary-digit:
`0`
`1`

integer-suffix:
- *unsigned-suffix long-suffix*$_{opt}$
- *unsigned-suffix long-long-suffix*$_{opt}$
- *long-suffix unsigned-suffix*$_{opt}$
- *long-long-suffix unsigned-suffix*$_{opt}$

unsigned-suffix: one of
`u U`
long-suffix: one of
`l L`
long-long-suffix: one of
`ll LL`
character-literal:
`'` *c-char-sequence* `'`
`u'` *c-char-sequence* `'`
`U'` *c-char-sequence* `'`
`L'` *c-char-sequence* `'`
c-char-sequence:
c-char
c-char-sequence c-char
c-char:
any member of the source character set except
the single-quote `'`, backslash `\`, or new-line character
escape-sequence
universal-character-name
escape-sequence:
simple-escape-sequence
octal-escape-sequence
hexadecimal-escape-sequence
simple-escape-sequence: one of
`\'` `\"` `\?` `\\`
`\a` `\b` `\f` `\n` `\r` `\t` `\v`
octal-escape-sequence:
`\` *octal-digit*
`\` *octal-digit octal-digit*
`\` *octal-digit octal-digit octal-digit*
hexadecimal-escape-sequence:
`\x` *hexadecimal-digit*
hexadecimal-escape-sequence hexadecimal-digit
floating-literal:
fractional-constant exponent-part$_{opt}$ *floating-suffix*$_{opt}$
digit-sequence exponent-part floating-suffix$_{opt}$
fractional-constant:
digit-sequence$_{opt}$ `.` *digit-sequence*
digit-sequence `.`
exponent-part:
`e` *sign*$_{opt}$ *digit-sequence*
`E` *sign*$_{opt}$ *digit-sequence*
sign: one of
`+ -`
digit-sequence:
digit
digit-sequence `'`$_{opt}$ *digit*
floating-suffix: one of
`f l F L`
string-literal:
encoding-prefix$_{opt}$`"` *s-char-sequence*$_{opt}$`"`
encoding-prefix$_{opt}$`R` *raw-string*

encoding-prefix:
`u8`
`u`
`U`
`L`

s-char-sequence:
s-char
s-char-sequence s-char

s-char:
any member of the source character set except
the double-quote `"`, backslash `\`, or new-line character
escape-sequence
universal-character-name

raw-string:
`"` *d-char-sequence*$_{opt}$`(` *r-char-sequence*$_{opt}$`)` *d-char-sequence*$_{opt}$`"`

r-char-sequence:
r-char
r-char-sequence r-char

r-char:
any member of the source character set, except
a right parenthesis `)` followed by the initial *d-char-sequence*
(which may be empty) followed by a double quote `"`.

d-char-sequence:
d-char
d-char-sequence d-char

d-char:
any member of the basic source character set except:
space, the left parenthesis `(`, the right parenthesis `)`, the backslash `\`,
and the control characters representing horizontal tab,
vertical tab, form feed, and newline.

boolean-literal:
`false`
`true`

pointer-literal:
`nullptr`

user-defined-literal:
user-defined-integer-literal
user-defined-floating-literal
user-defined-string-literal
user-defined-character-literal

user-defined-integer-literal:
decimal-literal ud-suffix
octal-literal ud-suffix
hexadecimal-literal ud-suffix
binary-literal ud-suffix

user-defined-floating-literal:
fractional-constant exponent-part$_{opt}$ *ud-suffix*
digit-sequence exponent-part ud-suffix

user-defined-string-literal:
string-literal ud-suffix

user-defined-character-literal:
character-literal ud-suffix

ud-suffix:
  identifier

A.3 Basic concepts [gram.basic]

translation-unit:

Annex B (informative) Implementation quantities [implimits]

1

Because computers are finite, C++ implementations are inevitably limited in the size of the programs they can successfully process. Every implementation shall document those limitations where known. This documentation may cite fixed limits where they exist, say how to compute variable limits as a function of available resources, or say that fixed limits do not exist or are unknown.

1

The limits may constrain quantities that include those described below or others. The bracketed number following each quantity is recommended as the minimum for that quantity. However, these quantities are only guidelines and do not determine compliance.

— Nesting levels of compound statements, iteration control structures, and selection control structures [256].

— Nesting levels of conditional inclusion [256].

— Pointer, array, and function declarators (in any combination) modifying a class, arithmetic, or incomplete type in a declaration [256].

— Nesting levels of parenthesized expressions within a full-expression [256].

— Number of characters in an internal identifier or macro name [1 024].

— Number of characters in an external identifier [1 024].

— External identifiers in one translation unit [65 536].

— Identifiers with block scope declared in one block [1 024].

— Macro identifiers simultaneously defined in one translation unit [65 536].

— Parameters in one function definition [256].

— Arguments in one function call [256].

— Parameters in one macro definition [256].

— Arguments in one macro invocation [256].

— Characters in one logical source line [65 536].

— Characters in a string literal (after concatenation) [65 536].

— Size of an object [262 144].

— Nesting levels for `#include` files [256].

— Case labels for a `switch` statement (excluding those for any nested `switch` statements) [16 384].

— Data members in a single class [16 384].

— Enumeration constants in a single enumeration [4 096].

— Levels of nested class definitions in a single *member-specification* [256].

— Functions registered by `atexit()` [32].

— Functions registered by `at_quick_exit()` [32].

— Direct and indirect base classes [16 384].

— Direct base classes for a single class [1 024].

— Members declared in a single class [4 096].

— Final overriding virtual functions in a class, accessible or not [16 384].

— Direct and indirect virtual bases of a class [1 024].

— Static members of a class [1 024].

— Friend declarations in a class [4 096].

— Access control declarations in a class [4 096].

— Member initializers in a constructor definition [6 144].

— Scope qualifications of one identifier [256].

— Nested external specifications [1 024].

— Recursive `constexpr` function invocations [512].

— Full-expressions evaluated within a core constant expression [1 048 576].

— Template arguments in a template declaration [1 024].

— Recursively nested template instantiations, including substitution during template argument deduction (14.2114.1) [1 024].

— Handlers per `try` block [256].

— Throw specifications on a single function declaration [256].

— Number of placeholders (20.379.0.1) [10].

Annex C (informative) Compatibility [diff]

C.1 C++ and ISO C [diff.iso]

1 This subclause lists the differences between C++ and ISO C, by the chapters of this document.

C.1.1 Clause 2: lexical conventions [diff.lex]

2.287
Change: New Keywords
New keywords are added to C++; see 2.287.
Rationale: These keywords were added in order to implement the new semantics of C++.
Effect on original feature: Change to semantics of well-defined feature. Any ISO C programs that used any of these keywords as identifiers are not valid C++ programs.
Difficulty of converting: Syntactic transformation. Converting one specific program is easy. Converting a large collection of related programs takes more work.
How widely used: Common.

2.356.1
Change: Type of character literal is changed from `int` to `char`
Rationale: This is needed for improved overloaded function argument type matching. For example:

```
int function( int i );
int function( char c );

function( 'x' );
```

It is preferable that this call match the second version of function rather than the first.
Effect on original feature: Change to semantics of well-defined feature. ISO C programs which depend on

```
sizeof('x') == sizeof(int)
```

will not work the same as C++ programs.
Difficulty of converting: Simple.
How widely used: Programs which depend upon `sizeof('x')` are probably rare.

Subclause 2.453.1:
Change: String literals made const
The type of a string literal is changed from "array of `char`" to "array of `const char`." The type of a `char16_t` string literal is changed from "array of *some-integer-type*" to "array of `const char16_t`." The type of a `char32_t` string literal is changed from "array of *some-integer-type*" to "array of `const char32_t`." The type of a wide string literal is changed from "array of `wchar_t`" to "array of `const wchar_t`."
Rationale: This avoids calling an inappropriate overloaded function, which might expect to be able to modify its argument.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Syntactic transformation. The fix is to add a cast:

```
char* p = "abc";              // valid in C, invalid in C++
void f(char*) {
  char* p = (char*)"abc";     // OK: cast added
```

```
  f(p);
  f((char*)"def");              // OK: cast added
}
```

How widely used: Programs that have a legitimate reason to treat string literals as pointers to potentially modifiable memory are probably rare.

C.1.2 Clause 3: basic concepts [diff.basic]

3.43
Change: C++ does not have "tentative definitions" as in C E.g., at file scope,

```
int i;
int i;
```

is valid in C, invalid in C++. This makes it impossible to define mutually referential file-local static objects, if initializers are restricted to the syntactic forms of C. For example,

```
struct X { int i; struct X* next; };

static struct X a;
static struct X b = { 0, &a };
static struct X a = { 1, &b };
```

Rationale: This avoids having different initialization rules for fundamental types and user-defined types.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation.
Rationale: In C++, the initializer for one of a set of mutually-referential file-local static objects must invoke a function call to achieve the initialization.
How widely used: Seldom.

3.464
Change: A `struct` is a scope in C++, not in C
Rationale: Class scope is crucial to C++, and a struct is a class.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: C programs use `struct` extremely frequently, but the change is only noticeable when `struct`, enumeration, or enumerator names are referred to outside the `struct`. The latter is probably rare.

3.1459 [also 7.519.1]
Change: A name of file scope that is explicitly declared `const`, and not explicitly declared `extern`, has internal linkage, while in C it would have external linkage
Rationale: Because `const` objects can be used as compile-time values in C++, this feature urges programmers to provide explicit initializer values for each `const`. This feature allows the user to put `const`objects in header files that are included in many compilation units.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation
How widely used: Seldom

3.1721
Change: Main cannot be called recursively and cannot have its address taken
Rationale: The main function may require special actions.
Effect on original feature: Deletion of semantically well-defined feature

Difficulty of converting: Trivial: create an intermediary function such as `mymain(argc, argv)`.
How widely used: Seldom

3.2955
Change: C allows "compatible types" in several places, C++ does not For example, otherwise-identical `struct` types with different tag names are "compatible" in C but are distinctly different types in C++.
Rationale: Stricter type checking is essential for C++.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. The "typesafe linkage" mechanism will find many, but not all, of such problems. Those problems not found by typesafe linkage will continue to function properly, according to the "layout compatibility rules" of this International Standard.
How widely used: Common.

C.1.3 Clause 4: standard conversions [diff.conv]

4.579
Change: Converting `void*` to a pointer-to-object type requires casting

```
char a[10];
void* b=a;
void foo() {
  char* c=b;
}
```

ISO C will accept this usage of pointer to void being assigned to a pointer to object type. C++ will not.
Rationale: C++ tries harder than C to enforce compile-time type safety.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Could be automated. Violations will be diagnosed by the C++ translator. The fix is to add a cast. For example:

```
char* c = (char*) b;
```

How widely used: This is fairly widely used but it is good programming practice to add the cast when assigning pointer-to-void to pointer-to-object. Some ISO C translators will give a warning if the cast is not used.

C.1.4 Clause 5: expressions [diff.expr]

5.955.1
Change: Implicit declaration of functions is not allowed
Rationale: The type-safe nature of C++.
Effect on original feature: Deletion of semantically well-defined feature. Note: the original feature was labeled as "obsolescent" in ISO C.
Difficulty of converting: Syntactic transformation. Facilities for producing explicit function declarations are fairly widespread commercially.
How widely used: Common.

5.2075.1, 5.2765
Change: Types must be declared in declarations, not in expressions In C, a sizeof expression or cast expression may create a new type. For example,

```
p = (void*)(struct x {int i;} *)0;
```

declares a new type, struct x .
Rationale: This prohibition helps to clarify the location of declarations in the source code.

Effect on original feature: Deletion of a semantically well-defined feature.
Difficulty of converting: Syntactic transformation.
How widely used: Seldom.

5.3337, 5.3483, 5.3602

Change: The result of a conditional expression, an assignment expression, or a comma expression may be an lvalue
Rationale: C++ is an object-oriented language, placing relatively more emphasis on lvalues. For example, functions may return lvalues.
Effect on original feature: Change to semantics of well-defined feature. Some C expressions that implicitly rely on lvalue-to-rvalue conversions will yield different results. For example,

```
char arr[100];
sizeof(0, arr)
```

yields `100` in C++ and `sizeof(char*)` in C.
Difficulty of converting: Programs must add explicit casts to the appropriate rvalue.
How widely used: Rare.

C.1.5 Clause 6: statements [diff.stat]

6.72.1, 6.413.1
Change: It is now invalid to jump past a declaration with explicit or implicit initializer (except across entire block not entered)
Rationale: Constructors used in initializers may allocate resources which need to be de-allocated upon leaving the block. Allowing jump past initializers would require complicated run-time determination of allocation. Furthermore, any use of the uninitialized object could be a disaster. With this simple compile-time rule, C++ assures that if an initialized variable is in scope, then it has assuredly been initialized.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Seldom.

6.270.2
Change: It is now invalid to return (explicitly or implicitly) from a function which is declared to return a value without actually returning a value
Rationale: The caller and callee may assume fairly elaborate return-value mechanisms for the return of class objects. If some flow paths execute a return without specifying any value, the implementation must embody many more complications. Besides, promising to return a value of a given type, and then not returning such a value, has always been recognized to be a questionable practice, tolerated only because very-old C had no distinction between void functions and int functions.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. Add an appropriate return value to the source code, such as zero.
How widely used: Seldom. For several years, many existing C implementations have produced warnings in this case.

C.1.6 Clause 7: declarations [diff.dcl]

7.49.1
Change: In C++, the `static` or `extern` specifiers can only be applied to names of objects or functions Using these specifiers with type declarations is illegal in C++. In C, these specifiers are ignored when used on type declarations.

Example:

```
static struct S {                // valid C, invalid in C++
  int i;
};
```

Rationale: Storage class specifiers don't have any meaning when associated with a type. In C++, class members can be declared with the `static` storage class specifier. Allowing storage class specifiers on type declarations could render the code confusing for users.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation.
How widely used: Seldom.

7.235.1
Change: A C++ typedef name must be different from any class type name declared in the same scope (except if the typedef is a synonym of the class name with the same name). In C, a typedef name and a struct tag name declared in the same scope can have the same name (because they have different name spaces)

Example:

```
typedef struct name1 { /*...*/ } name1;          // valid C and C++
struct name { /*...*/ };
typedef int name;                // valid C, invalid C++
```

Rationale: For ease of use, C++ doesn't require that a type name be prefixed with the keywords `class`, `struct` or `union` when used in object declarations or type casts.

Example:

```
class name { /*...*/ };
name i;                          // i has type class name
```

Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. One of the 2 types has to be renamed.
How widely used: Seldom.

7.519.1 [see also 3.1459]
Change: const objects must be initialized in C++ but can be left uninitialized in C
Rationale: A const object cannot be assigned to so it must be initialized to hold a useful value.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Seldom.

7.519.1
Change: Banning implicit int

In C++ a *decl-specifier-seq* must contain a *type-specifier*, unless it is followed by a declarator for a constructor, a destructor, or a conversion function. In the following example, the left-hand column presents valid C; the right-hand column presents equivalent C++:

```
void f(const parm);              void f(const int parm);
const n = 3;                     const int n = 3;
main()                           int main()
    /* ... */                        /* ... */
```

Rationale: In C++, implicit int creates several opportunities for ambiguity between expressions involving function-like casts and declarations. Explicit declaration is increasingly considered to be proper style. Liaison with WG14 (C) indicated support for (at least) deprecating implicit int in the next revision of C.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation. Could be automated.
How widely used: Common.

7.832.0.1
Change: The keyword `auto` cannot be used as a storage class specifier.

```
void f() {
  auto int x;      // valid C, invalid C++
}
```

Rationale: Allowing the use of `auto` to deduce the type of a variable from its initializer results in undesired interpretations of `auto` as a storage class specifier in certain contexts.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation.
How widely used: Rare.

7.1001
Change: C++ objects of enumeration type can only be assigned values of the same enumeration type. In C, objects of enumeration type can be assigned values of any integral type

Example:

```
enum color { red, blue, green };
enum color c = 1;                // valid C, invalid C++
```

Rationale: The type-safe nature of C++.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation. (The type error produced by the assignment can be automatically corrected by applying an explicit cast.)
How widely used: Common.

7.1001
Change: In C++, the type of an enumerator is its enumeration. In C, the type of an enumerator is `int`.

Example:

```
enum e { A };
sizeof(A) == sizeof(int)         // in C
sizeof(A) == sizeof(e)           // in C++
/* and sizeof(int) is not necessarily equal to sizeof(e) */
```

Rationale: In C++, an enumeration is a distinct type.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Seldom. The only time this affects existing C code is when the size of an enumerator is taken. Taking the size of an enumerator is not a common C coding practice.

C.1.7 Clause 8: declarators [diff.decl]

8.360.1

Change: In C++, a function declared with an empty parameter list takes no arguments. In C, an empty parameter list means that the number and type of the function arguments are unknown.

Example:

```
int f();            // means int f(void) in C++
                    // int f( unknown ) in C
```

Rationale: This is to avoid erroneous function calls (i.e., function calls with the wrong number or type of arguments).
Effect on original feature: Change to semantics of well-defined feature. This feature was marked as "obsolescent" in C.
Difficulty of converting: Syntactic transformation. The function declarations using C incomplete declaration style must be completed to become full prototype declarations. A program may need to be updated further if different calls to the same (non-prototype) function have different numbers of arguments or if the type of corresponding arguments differed.
How widely used: Common.

8.360.1 [see 5.2075.1]

Change: In C++, types may not be defined in return or parameter types. In C, these type definitions are allowed

Example:

```
void f( struct S { int a; } arg ) {}     // valid C, invalid C++
enum E { A, B, C } f() {}                // valid C, invalid C++
```

Rationale: When comparing types in different compilation units, C++ relies on name equivalence when C relies on structural equivalence. Regarding parameter types: since the type defined in an parameter list would be in the scope of the function, the only legal calls in C++ would be from within the function itself.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. The type definitions must be moved to file scope, or in header files.
How widely used: Seldom. This style of type definitions is seen as poor coding style.

8.706

Change: In C++, the syntax for function definition excludes the "old-style" C function. In C, "old-style" syntax is allowed, but deprecated as "obsolescent."
Rationale: Prototypes are essential to type safety.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation.
How widely used: Common in old programs, but already known to be obsolescent.

8.2115.1

Change: In C++, when initializing an array of character with a string, the number of characters in the string (including the terminating `'\0'`) must not exceed the number of elements in the array. In C, an array can be initialized with a string even if the array is not large enough to contain the string-terminating `'\0'`

Example:

```
char array[4] = "abcd";          // valid C, invalid C++
```

Rationale: When these non-terminated arrays are manipulated by standard string routines, there is potential for major catastrophe.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. The arrays must be declared one element bigger to contain the string terminating `'\0'`.
How widely used: Seldom. This style of array initialization is seen as poor coding style.

C.1.8 Clause 9: classes [diff.class]

9.172 [see also 7.235.1]
Change: In C++, a class declaration introduces the class name into the scope where it is declared and hides any object, function or other declaration of that name in an enclosing scope. In C, an inner scope declaration of a struct tag name never hides the name of an object or function in an outer scope

Example:

```
int x[99];
void f() {
  struct x { int a; };
  sizeof(x);  /* size of the array in C */
  /* size of the struct in C++ */
}
```

Rationale: This is one of the few incompatibilities between C and C++ that can be attributed to the new C++ name space definition where a name can be declared as a type and as a non-type in a single scope causing the non-type name to hide the type name and requiring that the keywords `class`, `struct`, `union` or `enum` be used to refer to the type name. This new name space definition provides important notational conveniences to C++ programmers and helps making the use of the user-defined types as similar as possible to the use of fundamental types. The advantages of the new name space definition were judged to outweigh by far the incompatibility with C described above.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation. If the hidden name that needs to be accessed is at global scope, the `::` C++ operator can be used. If the hidden name is at block scope, either the type or the struct tag has to be renamed.
How widely used: Seldom.

9.921
Change: Bit-fields of type plain `int` are signed.
Rationale: Leaving the choice of signedness to implementations could lead to inconsistent definitions of template specializations. For consistency, the implementation freedom was eliminated for non-dependent types, too.
Effect on original feature: The choise is implementation-defined in C, but not so in C++.
Difficulty of converting: Syntactic transformation.
How widely used: Seldom.

9.960
Change: In C++, the name of a nested class is local to its enclosing class. In C the name of the nested class belongs to the same scope as the name of the outermost enclosing class.

Example:

```
struct X {
  struct Y { /* ... */ } y;
};
```

```
struct Y yy;                    // valid C, invalid C++
```

Rationale: C++ classes have member functions which require that classes establish scopes. The C rule would leave classes as an incomplete scope mechanism which would prevent C++ programmers from maintaining locality within a class. A coherent set of scope rules for C++ based on the C rule would be very complicated and C++ programmers would be unable to predict reliably the meanings of nontrivial examples involving nested or local functions.
Effect on original feature: Change of semantics of well-defined feature.
Difficulty of converting: Semantic transformation. To make the struct type name visible in the scope of the enclosing struct, the struct tag could be declared in the scope of the enclosing struct, before the enclosing struct is defined. Example:

```
struct Y;                       // struct Y and struct X are at the same scope
struct X {
  struct Y { /* ... */ } y;
};
```

All the definitions of C struct types enclosed in other struct definitions and accessed outside the scope of the enclosing struct could be exported to the scope of the enclosing struct. Note: this is a consequence of the difference in scope rules, which is documented in 3.464.
How widely used: Seldom.

9.992
Change: In C++, a typedef name may not be redeclared in a class definition after being used in that definition

Example:

```
typedef int I;
struct S {
  I i;
  int I;                    // valid C, invalid C++
};
```

Rationale: When classes become complicated, allowing such a redefinition after the type has been used can create confusion for C++ programmers as to what the meaning of 'I' really is.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. Either the type or the struct member has to be renamed.
How widely used: Seldom.

C.1.9 Clause 12: special member functions [diff.special]

12.1577
Change: Copying volatile objects

The implicitly-declared copy constructor and implicitly-declared copy assignment operator cannot make a copy of a volatile lvalue. For example, the following is valid in ISO C:

```
struct X { int i; };
volatile struct X x1 = {0};
struct X x2(x1);                // invalid C++
struct X x3;
x3 = x1;                        // also invalid C++
```

Rationale: Several alternatives were debated at length. Changing the parameter to `volatile const X&` would greatly complicate the generation of efficient code for class objects. Discussion of providing two alternative signatures for these implicitly-defined operations raised unanswered concerns about creating ambiguities and complicating the rules that specify the formation of these operators according to the bases and members.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. If volatile semantics are required for the copy, a user-declared constructor or assignment must be provided. [*Note:* This user-declared constructor may be explicitly defaulted. — *end note*] If non-volatile semantics are required, an explicit `const_cast` can be used.
How widely used: Seldom.

C.1.10 Clause 16: preprocessing directives [diff.cpp]

16.238
Change: Whether `__STDC__` is defined and if so, what its value is, are implementation-defined
Rationale: C++ is not identical to ISO C. Mandating that `__STDC__` be defined would require that translators make an incorrect claim. Each implementation must choose the behavior that will be most useful to its marketplace.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Programs and headers that reference `__STDC__` are quite common.

C.2 C++ and ISO C++ 2003 [diff.cpp03]

1 This subclause lists the differences between C++ and ISO C++ 2003 (ISO/IEC 14882:2003, *Programming Languages — C++*), by the chapters of this document.

C.2.1 Clause 2: lexical conventions [diff.cpp03.lex]

2.214
Change: New kinds of string literals
Rationale: Required for new features.
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. Specifically, macros named `R`, `u8`, `u8R`, `u`, `uR`, `U`, `UR`, or `LR` will not be expanded when adjacent to a string literal but will be interpreted as part of the string literal. For example,

```
#define u8 "abc"
const char* s = u8"def";        // Previously "abcdef", now "def"
```

2.214
Change: User-defined literal string support
Rationale: Required for new features.
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard, as the following example illustrates.

```
#define _x "there"
"hello"_x         // #1
```

Previously, #1 would have consisted of two separate preprocessing tokens and the macro `_x` would have been expanded. In this International Standard, #1 consists of a single preprocessing tokens, so the macro is not expanded.

2.287
Change: New keywords

Rationale: Required for new features.
Effect on original feature: Added to Table 4, the following identifiers are new keywords: `alignas`, `alignof`, `char16_t`, `char32_t`, `constexpr`, `decltype`, `noexcept`, `nullptr`, `static_assert`, and `thread_local`. Valid C++ 2003 code using these identifiers is invalid in this International Standard.

2.300.1
Change: Type of integer literals
Rationale: C99 compatibility.
Effect on original feature: Certain integer literals larger than can be represented by `long` could change from an unsigned integer type to `signed long long`.

C.2.2 Clause 4: standard conversions [diff.cpp03.conv]

4.579
Change: Only literals are integer null pointer constants
Rationale: Removing surprising interactions with templates and constant expressions
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard, as the following example illustrates:

```
void f(void *);  // #1
void f(...);     // #2
template<int N> void g() {
  f(0*N);        // calls #2; used to call #1
}
```

C.2.3 Clause 5: expressions [diff.cpp03.expr]

5.2851
Change: Specify rounding for results of integer `/` and `%`
Rationale: Increase portability, C99 compatibility.
Effect on original feature: Valid C++ 2003 code that uses integer division rounds the result toward 0 or toward negative infinity, whereas this International Standard always rounds the result toward 0.

C.2.4 Clause 7: declarations [diff.cpp03.dcl.dcl]

7.40
Change: Remove `auto` as a storage class specifier
Rationale: New feature.
Effect on original feature: Valid C++ 2003 code that uses the keyword `auto` as a storage class specifier may be invalid in this International Standard. In this International Standard, `auto` indicates that the type of a variable is to be deduced from its initializer expression.

C.2.5 Clause 8: declarators [diff.cpp03.dcl.decl]

8.2435.1
Change: Narrowing restrictions in aggregate initializers
Rationale: Catches bugs.
Effect on original feature: Valid C++ 2003 code may fail to compile in this International Standard. For example, the following code is valid in C++ 2003 but invalid in this International Standard because `double` to `int` is a narrowing conversion:

```
int x[] = { 2.0 };
```

C.2.6 Clause 12: special member functions [diff.cpp03.special]

12.30, 12.807, 12.1577
Change: Implicitly-declared special member functions are defined as deleted when the implicit definition

would have been ill-formed.
Rationale: Improves template argument deduction failure.
Effect on original feature: A valid C++ 2003 program that uses one of these special member functions in a context where the definition is not required (e.g., in an expression that is not potentially evaluated) becomes ill-formed.

12.807 (destructors)
Change: User-declared destructors have an implicit exception specification.
Rationale: Clarification of destructor requirements.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard. In particular, destructors that throw exceptions will call `std::terminate()` (without calling `std::unexpected()`) if their exception specification is `noexcept` or `noexcept(true)`. For a throwing virtual destructor of a derived class, `std::terminate()` can be avoided only if the base class virtual destructor has an exception specification that is not `noexcept` and not `noexcept(true)`.

C.2.7 Clause 14: templates [diff.cpp03.temp]

14.97
Change: Remove `export`
Rationale: No implementation consensus.
Effect on original feature: A valid C++ 2003 declaration containing `export` is ill-formed in this International Standard.

14.326
Change: Remove whitespace requirement for nested closing template right angle brackets
Rationale: Considered a persistent but minor annoyance. Template aliases representing nonclass types would exacerbate whitespace issues.
Effect on original feature: Change to semantics of well-defined expression. A valid C++ 2003 expression containing a right angle bracket ("`>`") followed immediately by another right angle bracket may now be treated as closing two templates. For example, the following code is valid in C++ 2003 because "`>>`" is a right-shift operator, but invalid in this International Standard because "`>>`" closes two templates.

```
template <class T> struct X { };
template <int N> struct Y { };
X< Y< 1 >> 2 > > x;
```

14.1532.0.1
Change: Allow dependent calls of functions with internal linkage
Rationale: Overly constrained, simplify overload resolution rules.
Effect on original feature: A valid C++ 2003 program could get a different result than this International Standard.

C.2.8 Clause 17: library introduction [diff.cpp03.library]

17 – 30
Change: New reserved identifiers
Rationale: Required by new features.
Effect on original feature: Valid C++ 2003 code that uses any identifiers added to the C++ standard library by this International Standard may fail to compile or produce different results in This International Standard. A comprehensive list of identifiers used by the C++ standard library can be found in the Index of Library Names in this International Standard.

17.48.0.1
Change: New headers
Rationale: New functionality.

Effect on original feature: The following C++ headers are new: `<array>`, `<atomic>`, `<chrono>`, `<codecvt>`, `<condition_variable>`, `<forward_list>`, `<future>`, `<initializer_list>`, `<mutex>`, `<random>`, `<ratio>`, `<regex>`, `<scoped_allocator>`, `<system_error>`, `<thread>`, `<tuple>`, `<typeindex>`, `<type_traits>`, `<unordered_map>`, and `<unordered_set>`. In addition the following C compatibility headers are new: `<ccomplex>`, `<cfenv>`, `<cinttypes>`, `<cstdalign>`, `<cstdbool>`, `<cstdint>`, `<ctgmath>`, and `<cuchar>`. Valid C++ 2003 code that `#include`s headers with these names may be invalid in this International Standard.

17.143.0.1
Effect on original feature: Function `swap` moved to a different header
Rationale: Remove dependency on `<algorithm>` for `swap`.
Effect on original feature: Valid C++ 2003 code that has been compiled expecting swap to be in `<algorithm>` may have to instead include `<utility>`.

17.295.0.0.1
Change: New reserved namespace
Rationale: New functionality.
Effect on original feature: The global namespace `posix` is now reserved for standardization. Valid C++ 2003 code that uses a top-level namespace `posix` may be invalid in this International Standard.

17.563.0.1
Change: Additional restrictions on macro names
Rationale: Avoid hard to diagnose or non-portable constructs.
Effect on original feature: Names of attribute identifiers may not be used as macro names. Valid C++ 2003 code that defines `override`, `final`, `carries_dependency`, or `noreturn` as macros is invalid in this International Standard.

C.2.9 Clause 18: language support library [diff.cpp03.language.support]

18.159.1.1
Change: Linking `new` and `delete` operators
Rationale: The two throwing single-object signatures of `operator new` and `operator delete` are now specified to form the base functionality for the other operators. This clarifies that replacing just these two signatures changes others, even if they are not explicitly changed.
Effect on original feature: Valid C++ 2003 code that replaces global `new` or `delete` operators may execute differently in this International Standard. For example, the following program should write `"custom deallocation"` twice, once for the single-object delete and once for the array delete.

```
#include <cstdio>
#include <cstdlib>
#include <new>

void* operator new(std::size_t size) throw(std::bad_alloc) {
  return std::malloc(size);
}

void operator delete(void* ptr) throw() {
  std::puts("custom deallocation");
  std::free(ptr);
}

int main() {
  int* i = new int;
  delete i;                    // single-object delete
  int* a = new int[3];
  delete [] a;                 // array delete
```

```
  return 0;
}
```

18.159.1.1
Change: `operator new` may throw exceptions other than `std::bad_alloc`
Rationale: Consistent application of `noexcept`.
Effect on original feature: Valid C++ 2003 code that assumes that global `operator new` only throws `std::bad_alloc` may execute differently in this International Standard.

C.2.10 Clause 19: diagnostics library [diff.cpp03.diagnostics]

19.12
Change: Thread-local error numbers
Rationale: Support for new thread facilities.
Effect on original feature: Valid but implementation-specific C++ 2003 code that relies on `errno` being the same across threads may change behavior in this International Standard.

C.2.11 Clause 20: general utilities library [diff.cpp03.utilities]

20.85.1
Change: Minimal support for garbage-collected regions
Rationale: Required by new feature.
Effect on original feature: Valid C++ 2003 code, compiled without traceable pointer support, that interacts with newer C++ code using regions declared reachable may have different runtime behavior.

20.339.1, 20.339.2, 20.339.3, 20.357.1, 20.357.2, 20.357.3
Change: Standard function object types no longer derived from `std::unary_function` or `std::binary_function`
Rationale: Superseded by new feature.
Effect on original feature: Valid C++ 2003 code that depends on function object types being derived from `unary_function` or `binary_function` will execute differently in this International Standard.

C.2.12 Clause 21: strings library [diff.cpp03.strings]

21.26
Change: `basic_string` requirements no longer allow reference-counted strings
Rationale: Invalidation is subtly different with reference-counted strings. This change regularizes behavior for this International Standard.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard.

21.31.1
Change: Loosen `basic_string` invalidation rules
Rationale: Allow small-string optimization.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard. Some `const` member functions, such as `data` and `c_str`, no longer invalidate iterators.

C.2.13 Clause 23: containers library [diff.cpp03.containers]

23.2
Change: Complexity of `size()` member functions now constant
Rationale: Lack of specification of complexity of `size()` resulted in divergent implementations with inconsistent performance characteristics.
Effect on original feature: Some container implementations that conform to C++ 2003 may not conform to the specified `size()` requirements in this International Standard. Adjusting containers such as `std::list` to the stricter requirements may require incompatible changes.

23.2
Change: Requirements change: relaxation
Rationale: Clarification.
Effect on original feature: Valid C++ 2003 code that attempts to meet the specified container requirements may now be over-specified. Code that attempted to be portable across containers may need to be adjusted as follows:

— not all containers provide `size()`; use `empty()` instead of `size() == 0`;

— not all containers are empty after construction (`array`);

— not all containers have constant complexity for `swap()` (`array`).

23.2
Change: Requirements change: default constructible
Rationale: Clarification of container requirements.
Effect on original feature: Valid C++ 2003 code that attempts to explicitly instantiate a container using a user-defined type with no default constructor may fail to compile.

23.224.1, 23.294.1
Change: Signature changes: from `void` return types
Rationale: Old signature threw away useful information that may be expensive to recalculate.
Effect on original feature: The following member functions have changed:

— `erase(iter)` for `set`, `multiset`, `map`, `multimap`

— `erase(begin, end)` for `set`, `multiset`, `map`, `multimap`

— `insert(pos, num, val)` for `vector`, `deque`, `list`, `forward_list`

— `insert(pos, beg, end)` for `vector`, `deque`, `list`, `forward_list`

Valid C++ 2003 code that relies on these functions returning `void` (e.g., code that creates a pointer to member function that points to one of these functions) will fail to compile with this International Standard.

23.224.1, 23.294.1
Change: Signature changes: from `iterator` to `const_iterator` parameters
Rationale: Overspecification. *Effects:* The signatures of the following member functions changed from taking an `iterator` to taking a `const_iterator`:

— `insert(iter, val)` for `vector`, `deque`, `list`, `set`, `multiset`, `map`, `multimap`

— `insert(pos, beg, end)` for `vector`, `deque`, `list`, `forward_list`

— `erase(iter)` for `set`, `multiset`, `map`, `multimap`

— `erase(begin, end)` for `set`, `multiset`, `map`, `multimap`

— all forms of `list::splice`

— all forms of `list::merge`

Valid C++ 2003 code that uses these functions may fail to compile with this International Standard.

23.224.1, 23.294.1
Change: Signature changes: `resize`
Rationale: Performance, compatibility with move semantics.
Effect on original feature: For `vector`, `deque`, and `list` the fill value passed to `resize` is now passed by reference instead of by value, and an additional overload of `resize` has been added. Valid C++ 2003 code that uses this function may fail to compile with this International Standard.

C.2.14 Clause 25: algorithms library [diff.cpp03.algorithms]

25.1

Change: Result state of inputs after application of some algorithms
Rationale: Required by new feature.
Effect on original feature: A valid C++ 2003 program may detect that an object with a valid but unspecified state has a different valid but unspecified state with this International Standard. For example, `std::remove` and `std::remove_if` may leave the tail of the input sequence with a different set of values than previously.

C.2.15 Clause 26: numerics library [diff.cpp03.numerics]

26.11

Change: Specified representation of complex numbers
Rationale: Compatibility with C99.
Effect on original feature: Valid C++ 2003 code that uses implementation-specific knowledge about the binary representation of the required template specializations of `std::complex` may not be compatible with this International Standard.

C.2.16 Clause 27: Input/output library [diff.cpp03.input.output]

27.117.0.0.2, 27.190.0.2, 27.84.0.1

Change: Specify use of explicit in existing boolean conversion operators
Rationale: Clarify intentions, avoid workarounds.
Effect on original feature: Valid C++ 2003 code that relies on implicit boolean conversions will fail to compile with this International Standard. Such conversions occur in the following conditions:

— passing a value to a function that takes an argument of type `bool`;

— using `operator==` to compare to `false` or `true`;

— returning a value from a function with a return type of `bool`;

— initializing members of type `bool` via aggregate initialization;

— initializing a `const bool&` which would bind to a temporary.

27.59.0.1.1

Change: Change base class of `std::ios_base::failure`
Rationale: More detailed error messages.
Effect on original feature: `std::ios_base::failure` is no longer derived directly from `std::exception`, but is now derived from `std::system_error`, which in turn is derived from `std::runtime_error`. Valid C++ 2003 code that assumes that `std::ios_base::failure` is derived directly from `std::exception` may execute differently in this International Standard.

27.58.1

Change: Flag types in `std::ios_base` are now bitmasks with values defined as constexpr static members
Rationale: Required for new features.
Effect on original feature: Valid C++ 2003 code that relies on `std::ios_base` flag types being represented as `std::bitset` or as an integer type may fail to compile with this International Standard. For example:

```
#include <iostream>

int main() {
  int flag = std::ios_base::hex;
  std::cout.setf(flag);          // error: setf does not take argument of type int
  return 0;
}
```

C.3 C++ and ISO C++ 2011 [diff.cpp11]

1 This subclause lists the differences between C++ and ISO C++ 2011 (ISO/IEC 14882:2011, *Programming Languages — C++*), by the chapters of this document.

C.3.1 Clause 2: lexical conventions [diff.cpp11.lex]

2.266
Change: *pp-number* can contain one or more single quotes.
Rationale: Necessary to enable single quotes as digit separators.
Effect on original feature: Valid C++ 2011 code may fail to compile or may change meaning in this International Standard. For example, the following code is valid both in C++ 2011 and in this International Standard, but the macro invocation produces different outcomes because the single quotes delimit a character literal in C++ 2011, whereas they are digit separators in this International Standard:

```
#define M(x, ...) __VA_ARGS__
int x[2] = { M(1'2,3'4) };
// int x[2] = {};       — C++ 2011
// int x[2] = { 3'4 };  — this International Standard
```

C.3.2 Clause 3: basic concepts [diff.cpp11.basic]

3.2428.0.1
Change: New usual (non-placement) deallocator
Rationale: Required for sized deallocation.
Effect on original feature: Valid C++ 2011 code could declare a global placement allocation function and deallocation function as follows:

```
void operator new(std::size_t, std::size_t);
void operator delete(void*, std::size_t) noexcept;
```

In this International Standard, however, the declaration of `operator delete` might match a predefined usual (non-placement) `operator delete` (3.2331.1). If so, the program is ill-formed, as it was for class member allocation functions and deallocation functions (5.2221.1).

C.3.3 Clause 7: declarations [diff.cpp11.dcl.dcl]

7.328.1
Change: `constexpr` non-static member functions are not implicitly `const` member functions.
Rationale: Necessary to allow `constexpr` member functions to mutate the object.
Effect on original feature: Valid C++ 2011 code may fail to compile in this International Standard. For example, the following code is valid in C++ 2011 but invalid in this International Standard because it declares the same member function twice with different return types:

```
struct S {
  constexpr const int &f();
  int &f();
};
```

C.3.4 Clause 27: input/output library [diff.cpp11.input.output]

27.310.1
Change: `gets` is not defined.
Rationale: Use of `gets` is considered dangerous.
Effect on original feature: Valid C++ 2011 code that uses the `gets` function may fail to compile in this International Standard.

C.4 C standard library [diff.library]

1

This subclause summarizes the contents of the C++ standard library included from the Standard C library. It also summarizes the explicit changes in definitions, declarations, or behavior from the Standard C library noted in other subclauses (17.48.0.1, 18.2, 21.261).

1 The C++ standard library provides 57 standard macros from the C library, as shown in Table 150.

2 The header names (enclosed in < and >) indicate that the macro may be defined in more than one header. All such definitions are equivalent (3.91).

Table 150 — Standard macros

assert	HUGE_VAL	NULL <cstring>	SIGINT	va_end
BUFSIZ	LC_ALL	NULL <ctime>	SIGSEGV	va_start
CLOCKS_PER_SEC	LC_COLLATE	NULL <cwchar>	SIGTERM	WCHAR_MAX
EDOM	LC_CTYPE	offsetof	SIG_DFL	WCHAR_MIN
EILSEQ	LC_MONETARY	RAND_MAX	SIG_ERR	WEOF <cwchar>
EOF	LC_NUMERIC	SEEK_CUR	SIG_IGN	WEOF <cwctype>
ERANGE	LC_TIME	SEEK_END	stderr	_IOFBF
errno	L_tmpnam	SEEK_SET	stdin	_IOLBF
EXIT_FAILURE	MB_CUR_MAX	setjmp	stdout	_IONBF
EXIT_SUCCESS	NULL <clocale>	SIGABRT	TMP_MAX	
FILENAME_MAX	NULL <cstddef>	SIGFPE	va_arg	
FOPEN_MAX	NULL <cstdlib>	SIGILL	va_copy	

3 The C++ standard library provides 57 standard values from the C library, as shown in Table 151.

Table 151 — Standard values

CHAR_BIT	FLT_DIG	INT_MIN	MB_LEN_MAX
CHAR_MAX	FLT_EPSILON	LDBL_DIG	SCHAR_MAX

C.6.1 Modifications to headers [diff.mods.to.headers]

1

For compatibility with the Standard C library, the C++ standard library provides the C headers enumerated in D.9, but their use is deprecated in C++.

C.11.1 Modifications to definitions [diff.mods.to.definitions]

C.11.1.1 Types `char16_t` and `char32_t` [diff.char16]

1 The types `char16_t` and `char32_t` are distinct types rather than typedefs to existing integral types.

C.11.1.2 Type `wchar_t` [diff.wchar.t]

1 `wchar_t` is a keyword in this International Standard (2.287). It does not appear as a type name defined in any of `<cstddef>`, `<cstdlib>`, or `<cwchar>` (21.261).

C.11.1.3 Header `<iso646.h>` [diff.header.iso646.h]

1 The tokens `and`, `and_eq`, `bitand`, `bitor`, `compl`, `not_eq`, `not`, `or`, `or_eq`, `xor`, and `xor_eq` are keywords in this International Standard (2.287). They do not appear as macro names defined in `<ciso646>`.

C.11.1.4 Macro `NULL` [diff.null]

1

The macro `NULL`, defined in any of `<clocale>`, `<cstddef>`, `<cstdio>`, `<cstdlib>`, `<cstring>`, `<ctime>`, or `<cwchar>`, is an implementation-defined C++ null pointer constant in this International Standard (18.2).

C.32.1 Modifications to declarations [diff.mods.to.declarations]

1 Header `<cstring>`: The following functions have different declarations:

(1.1) — `strchr`

(1.2) — `strpbrk`

(1.3) — `strrchr`

(1.4) — `strstr`

(1.5) — `memchr`

21.261 describes the changes.

C.32.2 Modifications to behavior [diff.mods.to.behavior]

1 Header `<cstdlib>`: The following functions have different behavior:

(1.1) — `atexit`

(1.2) — `exit`

(1.3) — `abort`

18.127 describes the changes.

2 Header `<csetjmp>`: The following functions have different behavior:

(2.1) — `longjmp`

18.295 describes the changes.

C.32.2.1 Macro `offsetof(type, member-designator)` [diff.offsetof]

1

The macro `offsetof`, defined in `<cstddef>`, accepts a restricted set of `type` arguments in this International Standard. 18.2 describes the change.

C.33.0.1 Memory allocation functions [diff.malloc]

1 The functions `calloc`, `malloc`, and `realloc` are restricted in this International Standard. 20.116.1 describes the changes.

Annex D (normative) Compatibility features [depr]

1 This Clause describes features of the C++ Standard that are specified for compatibility with existing implementations.

2

These are deprecated features, where *deprecated* is defined as: Normative for the current edition of the Standard, but having been identified as a candidate for removal from future revisions. An implementation may declare library names and entities described in this section with the `deprecated` attribute (7.1576.1).

D.3 Increment operator with `bool` operand [depr.incr.bool]

1 The use of an operand of type `bool` with the `++` operator is deprecated (see 5.2054.1 and 5.1264.1).

D.4 `register` keyword [depr.register]

1

The use of the `register` keyword as a *storage-class-specifier* (7.49.1) is deprecated.

D.6 Implicit declaration of copy functions [depr.impldec]

1

The implicit definition of a copy constructor as defaulted is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor. The implicit definition of a copy assignment operator as defaulted is deprecated if the class has a user-declared copy constructor or a user-declared destructor (12.807, 12.1577). In a future revision of this International Standard, these implicit definitions could become deleted (8.706).

D.8 Dynamic exception specifications [depr.except.spec]

1 The use of *dynamic-exception-specification*s is deprecated.

D.9 C standard library headers [depr.c.headers]

1

For compatibility with the C standard library and the C Unicode TR, the C++ standard library provides the 26 *C headers*, as shown in Table 155.

Table 155 — C headers

`<assert.h>`	`<inttypes.h>`	`<signal.h>`	`<stdio.h>`	`<wchar.h>`
`<complex.h>`	`<iso646.h>`	`<stdalign.h>`	`<stdlib.h>`	`<wctype.h>`
`<ctype.h>`	`<limits.h>`	`<stdarg.h>`	`<string.h>`	
`<errno.h>`	`<locale.h>`	`<stdbool.h>`	`<tgmath.h>`	
`<fenv.h>`	`<math.h>`	`<stddef.h>`	`<time.h>`	
`<float.h>`	`<setjmp.h>`	`<stdint.h>`	`<uchar.h>`	

1

Every C header, each of which has a name of the form `name.h`, behaves as if each name placed in the standard library namespace by the corresponding `c`*`name`* header is placed within the global namespace scope. It is unspecified whether these names are first declared or defined within namespace scope (3.736.1) of the namespace `std` and are then injected into the global namespace scope by explicit *using-declarations* (7.1311.1).

1

[*Example:* The header `<cstdlib>` assuredly provides its declarations and definitions within the namespace `std`. It may also provide these names within the global namespace. The header `<stdlib.h>` assuredly provides the same declarations and definitions within the global namespace, much as in the C Standard. It may also provide these names within the namespace `std`. — *end example*]

D.53 Old iostreams members [depr.ios.members]

1 The following member names are in addition to names specified in Clause 27:

```
namespace std {
  class ios_base {
  public:
    typedef T1 io_state;
    typedef T2 open_mode;
    typedef T3 seek_dir;
    typedef implementation-defined streamoff;
    typedef implementation-defined streampos;
    // remainder unchanged
  };
}
```

2 The type `io_state` is a synonym for an integer type (indicated here as `T1`) that permits certain member functions to overload others on parameters of type `iostate` and provide the same behavior.

3 The type `open_mode` is a synonym for an integer type (indicated here as `T2`) that permits certain member functions to overload others on parameters of type `openmode` and provide the same behavior.

4 The type `seek_dir` is a synonym for an integer type (indicated here as `T3`) that permits certain member functions to overload others on parameters of type `seekdir` and provide the same behavior.

5 The type `streamoff` is an implementation-defined type that satisfies the requirements of off_type in 27.2.2.

6 The type `streampos` is an implementation-defined type that satisfies the requirements of pos_type in 27.2.2.

7 An implementation may provide the following additional member function, which has the effect of calling `sbumpc()` (27.96.0.2.3):

```
namespace std {
  template<class charT, class traits = char_traits<charT> >
  class basic_streambuf {
  public:
    void stossc();
    // remainder unchanged
  };
}
```

8 An implementation may provide the following member functions that overload signatures specified in Clause 27:

```
namespace std {
  template<class charT, class traits> class basic_ios {
  public:
    void clear(io_state state);
```

```
    void setstate(io_state state);
    void exceptions(io_state);
    // remainder unchanged
  };

  class ios_base {
  public:
    // remainder unchanged
  };

  template<class charT, class traits = char_traits<charT> >
  class basic_streambuf {
  public:
    pos_type pubseekoff(off_type off, ios_base::seek_dir way,
              ios_base::open_mode which = ios_base::in | ios_base::out);
    pos_type pubseekpos(pos_type sp,
              ios_base::open_mode which);
    // remainder unchanged
  };

  template <class charT, class traits = char_traits<charT> >
  class basic_filebuf : public basic_streambuf<charT,traits> {
  public:
    basic_filebuf<charT,traits>* open
    (const char* s, ios_base::open_mode mode);
    // remainder unchanged
  };

  template <class charT, class traits = char_traits<charT> >
  class basic_ifstream : public basic_istream<charT,traits> {
  public:
    void open(const char* s, ios_base::open_mode mode);
    // remainder unchanged
  };

  template <class charT, class traits = char_traits<charT> >
  class basic_ofstream : public basic_ostream<charT,traits> {
  public:
    void open(const char* s, ios_base::open_mode mode);
    // remainder unchanged
  };
}
```

9 The effects of these functions is to call the corresponding member function specified in Clause 27.

D.54 `char*` streams [depr.str.strstreams]

1 The header `<strstream>` defines three types that associate stream buffers with character array objects and assist reading and writing such objects.

D.54.1 Class `strstreambuf` [depr.strstreambuf]

```
namespace std {
  class strstreambuf : public basic_streambuf<char> {
  public:
    explicit strstreambuf(streamsize alsize_arg = 0);
```

```
    strstreambuf(void* (*palloc_arg)(size_t), void (*pfree_arg)(void*));
    strstreambuf(char* gnext_arg, streamsize n, char* pbeg_arg = 0);
    strstreambuf(const char* gnext_arg, streamsize n);

    strstreambuf(signed char* gnext_arg, streamsize n,
                 signed char* pbeg_arg = 0);
    strstreambuf(const signed char* gnext_arg, streamsize n);
    strstreambuf(unsigned char* gnext_arg, streamsize n,
                 unsigned char* pbeg_arg = 0);
    strstreambuf(const unsigned char* gnext_arg, streamsize n);

    virtual ~strstreambuf();

    void  freeze(bool freezefl = true);
    char* str();
    int   pcount();

  protected:
    virtual int_type overflow (int_type c = EOF);
    virtual int_type pbackfail(int_type c = EOF);
    virtual int_type underflow();
    virtual pos_type seekoff(off_type off, ios_base::seekdir way,
                             ios_base::openmode which
                               = ios_base::in | ios_base::out);
    virtual pos_type seekpos(pos_type sp, ios_base::openmode which
                               = ios_base::in | ios_base::out);
    virtual streambuf* setbuf(char* s, streamsize n);

  private:
    typedef T1 strstate;              // exposition only
    static const strstate allocated;  // exposition only
    static const strstate constant;   // exposition only
    static const strstate dynamic;    // exposition only
    static const strstate frozen;     // exposition only
    strstate strmode;                 // exposition only
    streamsize alsize;                // exposition only
    void* (*palloc)(size_t);          // exposition only
    void (*pfree)(void*);             // exposition only
  };
}
```

1 The class `strstreambuf` associates the input sequence, and possibly the output sequence, with an object of some *character* array type, whose elements store arbitrary values. The array object has several attributes.

2 [*Note:* For the sake of exposition, these are represented as elements of a bitmask type (indicated here as `T1`) called `strstate`. The elements are:

(2.1) — `allocated`, set when a dynamic array object has been allocated, and hence should be freed by the destructor for the `strstreambuf` object;

(2.2) — `constant`, set when the array object has `const` elements, so the output sequence cannot be written;

(2.3) — `dynamic`, set when the array object is allocated (or reallocated) as necessary to hold a character sequence that can change in length;

(2.4) — `frozen`, set when the program has requested that the array object not be altered, reallocated, or freed.

— *end note*]

3 [*Note:* For the sake of exposition, the maintained data is presented here as:

(3.1) — `strstate strmode`, the attributes of the array object associated with the `strstreambuf` object;

(3.2) — `int alsize`, the suggested minimum size for a dynamic array object;

(3.3) — `void* (*palloc)(size_t)`, points to the function to call to allocate a dynamic array object;

(3.4) — `void (*pfree)(void*)`, points to the function to call to free a dynamic array object.

— *end note*]

4 Each object of class `strstreambuf` has a *seekable area*, delimited by the pointers `seeklow` and `seekhigh`. If `gnext` is a null pointer, the seekable area is undefined. Otherwise, `seeklow` equals `gbeg` and `seekhigh` is either `pend`, if `pend` is not a null pointer, or `gend`.

D.54.1.1 `strstreambuf` constructors [depr.strstreambuf.cons]

```
explicit strstreambuf(streamsize alsize_arg = 0);
```

1 *Effects:* Constructs an object of class `strstreambuf`, initializing the base class with `streambuf()`. The postconditions of this function are indicated in Table 156.

Table 156 — `strstreambuf(streamsize)` effects

Element	Value
`strmode`	`dynamic`
`alsize`	`alsize_arg`
`palloc`	a null pointer
`pfree`	a null pointer

```
strstreambuf(void* (*palloc_arg)(size_t), void (*pfree_arg)(void*));
```

2 *Effects:* Constructs an object of class `strstreambuf`, initializing the base class with `streambuf()`. The postconditions of this function are indicated in Table 157.

Table 157 — `strstreambuf(void* (*)(size_t), void (*)(void*))` effects

Element	Value
`strmode`	`dynamic`
`alsize`	an unspecified value
`palloc`	`palloc_arg`
`pfree`	`pfree_arg`

```
strstreambuf(char* gnext_arg, streamsize n, char* pbeg_arg = 0);
strstreambuf(signed char* gnext_arg, streamsize n,
             signed char* pbeg_arg = 0);
strstreambuf(unsigned char* gnext_arg, streamsize n,
             unsigned char* pbeg_arg = 0);
```

3 *Effects:* Constructs an object of class `strstreambuf`, initializing the base class with `streambuf()`. The postconditions of this function are indicated in Table 158.

4

Table 158 — `strstreambuf(charT*, streamsize, charT*)` effects

Element	Value
`strmode`	0
`alsize`	an unspecified value
`palloc`	a null pointer
`pfree`	a null pointer

`gnext_arg` shall point to the first element of an array object whose number of elements `N` is determined as follows:

— If `n > 0`, `N` is `n`.

— If `n == 0`, `N` is `std::strlen(gnext_arg)`.

— If `n < 0`, `N` is `INT_MAX`.[337]

1 If `pbeg_arg` is a null pointer, the function executes:

```
setg(gnext_arg, gnext_arg, gnext_arg + N);
```

2 Otherwise, the function executes:

```
setg(gnext_arg, gnext_arg, pbeg_arg);
setp(pbeg_arg,  pbeg_arg + N);
```

```
strstreambuf(const char* gnext_arg, streamsize n);
strstreambuf(const signed char* gnext_arg, streamsize n);
strstreambuf(const unsigned char* gnext_arg, streamsize n);
```

3 *Effects:* Behaves the same as `strstreambuf((char*)gnext_arg,n)`, except that the constructor also sets `constant` in `strmode`.

```
virtual ~strstreambuf();
```

4

Effects: Destroys an object of class `strstreambuf`. The function frees the dynamically allocated array object only if `strmode & allocated != 0` and `strmode & frozen == 0`. (D.56.0.2 describes how a dynamically allocated array object is freed.)

D.56.0.1 Member functions [depr.strstreambuf.members]

```
void freeze(bool freezefl = true);
```

1 *Effects:* If `strmode` & `dynamic` is non-zero, alters the freeze status of the dynamic array object as follows:

(1.1) — If `freezefl` is `true`, the function sets `frozen` in `strmode`.

(1.2) — Otherwise, it clears `frozen` in `strmode`.

```
char* str();
```

2 *Effects:* Calls `freeze()`, then returns the beginning pointer for the input sequence, `gbeg`.

3 *Remarks:* The return value can be a null pointer.

337) The function signature `strlen(const char*)` is declared in `<cstring>`. (21.261). The macro `INT_MAX` is defined in `<climits>` (18.41).

```
int pcount() const;
```

4 *Effects:* If the next pointer for the output sequence, `pnext`, is a null pointer, returns zero. Otherwise, returns the current effective length of the array object as the next pointer minus the beginning pointer for the output sequence, `pnext - pbeg`.

D.56.0.2 `strstreambuf` overridden virtual functions [depr.strstreambuf.virtuals]

```
int_type overflow(int_type c = EOF);
```

1 *Effects:* Appends the character designated by `c` to the output sequence, if possible, in one of two ways:

(1.1) — If `c != EOF` and if either the output sequence has a write position available or the function makes a write position available (as described below), assigns `c` to `*pnext++`.
Returns `(unsigned char)c`.

(1.2) — If `c == EOF`, there is no character to append.
Returns a value other than `EOF`.

2 Returns `EOF` to indicate failure.

3 *Remarks:* The function can alter the number of write positions available as a result of any call.

4 To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements `n` to hold the current array object (if any), plus at least one additional write position. How many additional write positions are made available is otherwise unspecified.[338] If `palloc` is not a null pointer, the function calls `(*palloc)(n)` to allocate the new dynamic array object. Otherwise, it evaluates the expression `new charT[n]`. In either case, if the allocation fails, the function returns `EOF`. Otherwise, it sets `allocated` in `strmode`.

5 To free a previously existing dynamic array object whose first element address is `p`: If `pfree` is not a null pointer, the function calls `(*pfree)(p)`. Otherwise, it evaluates the expression `delete[]p`.

6 If `strmode & dynamic == 0`, or if `strmode & frozen != 0`, the function cannot extend the array (reallocate it with greater length) to make a write position available.

```
int_type pbackfail(int_type c = EOF);
```

7 Puts back the character designated by `c` to the input sequence, if possible, in one of three ways:

(7.1) — If `c != EOF`, if the input sequence has a putback position available, and if `(char)c == gnext[-1]`, assigns `gnext - 1` to `gnext`.
Returns `c`.

(7.2) — If `c != EOF`, if the input sequence has a putback position available, and if `strmode` & `constant` is zero, assigns `c` to `*--gnext`.
Returns `c`.

(7.3) — If `c == EOF` and if the input sequence has a putback position available, assigns `gnext - 1` to `gnext`.
Returns a value other than `EOF`.

8 Returns `EOF` to indicate failure.

9 *Remarks:* If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

```
int_type underflow();
```

338) An implementation should consider `alsize` in making this decision.

10 *Effects:* Reads a character from the *input sequence*, if possible, without moving the stream position past it, as follows:

(10.1) — If the input sequence has a read position available, the function signals success by returning `(unsigned char)*gnext`.

(10.2) — Otherwise, if the current write next pointer `pnext` is not a null pointer and is greater than the current read end pointer `gend`, makes a *read position* available by assigning to `gend` a value greater than `gnext` and no greater than `pnext`.

Returns `(unsigned char*)gnext`.

11 Returns `EOF` to indicate failure.

12 *Remarks:* The function can alter the number of read positions available as a result of any call.

```
pos_type seekoff(off_type off, seekdir way, openmode which = in | out);
```

13 *Effects:* Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 159.

Table 159 — `seekoff` positioning

Conditions	Result
`(which & ios::in) != 0`	positions the input sequence
`(which & ios::out) != 0`	positions the output sequence
`(which & (ios::in | ios::out)) == (ios::in | ios::out))` and `way ==` either `ios::beg` or `ios::end`	positions both the input and the output sequences
Otherwise	the positioning operation fails.

14 For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines `newoff` as indicated in Table 160.

Table 160 — `newoff` values

Condition	`newoff` Value
`way == ios::beg`	0
`way == ios::cur`	the next pointer minus the beginning pointer (`xnext - xbeg`).
`way == ios::end`	`seekhigh` minus the beginning pointer (`seekhigh - xbeg`).

15 If `(newoff + off) < (seeklow - xbeg)` or `(seekhigh - xbeg) < (newoff + off)`, the positioning operation fails. Otherwise, the function assigns `xbeg + newoff + off` to the next pointer `xnext`.

16 *Returns:* `pos_type(newoff)`, constructed from the resultant offset `newoff` (of type `off_type`), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is `pos_type(off_type(-1))`.

```
pos_type seekpos(pos_type sp, ios_base::openmode which
                 = ios_base::in | ios_base::out);
```

17 *Effects:* Alters the stream position within one of the controlled sequences, if possible, to correspond to the stream position stored in `sp` (as described below).

(17.1) — If `(which & ios::in) != 0`, positions the input sequence.

(17.2) — If `(which & ios::out) != 0`, positions the output sequence.

(17.3) — If the function positions neither sequence, the positioning operation fails.

18 For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines `newoff` from `sp.offset()`:

(18.1) — If `newoff` is an invalid stream position, has a negative value, or has a value greater than (`seekhigh - seeklow`), the positioning operation fails

(18.2) — Otherwise, the function adds `newoff` to the beginning pointer `xbeg` and stores the result in the next pointer `xnext`.

19 *Returns:* `pos_type(newoff)`, constructed from the resultant offset `newoff` (of type `off_type`), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is `pos_type(off_type(-1))`.

```
streambuf<char>* setbuf(char* s, streamsize n);
```

20 *Effects:* Implementation defined, except that `setbuf(0, 0)` has no effect.

D.56.1 Class `istrstream` [depr.istrstream]

```
namespace std {
  class istrstream : public basic_istream<char> {
  public:
    explicit istrstream(const char* s);
    explicit istrstream(char* s);
    istrstream(const char* s, streamsize n);
    istrstream(char* s, streamsize n);
    virtual ~istrstream();

    strstreambuf* rdbuf() const;
    char* str();
  private:
    strstreambuf sb;  // exposition only
  };
}
```

1 The class `istrstream` supports the reading of objects of class `strstreambuf`. It supplies a `strstreambuf` object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

(1.1) — `sb`, the `strstreambuf` object.

D.56.1.1 `istrstream` constructors [depr.istrstream.cons]

```
explicit istrstream(const char* s);
explicit istrstream(char* s);
```

1 *Effects:* Constructs an object of class `istrstream`, initializing the base class with `istream(&sb)` and initializing `sb` with `strstreambuf(s,0))`. `s` shall designate the first element of an NTBS.

```
istrstream(const char* s, streamsize n);
```

2 *Effects:* Constructs an object of class `istrstream`, initializing the base class with `istream(&sb)` and initializing `sb` with `strstreambuf(s,n))`. `s` shall designate the first element of an array whose length is `n` elements, and `n` shall be greater than zero.

D.56.1.2 Member functions [depr.istrstream.members]

```
strstreambuf* rdbuf() const;
```

1 *Returns:* `const_cast<strstreambuf*>(&sb)`.

```
char* str();
```

2 *Returns:* `rdbuf()->str()`.

D.56.2 Class `ostrstream` [depr.ostrstream]

```
namespace std {
  class ostrstream : public basic_ostream<char> {
  public:
    ostrstream();
    ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);
    virtual ~ostrstream();

    strstreambuf* rdbuf() const;
    void freeze(bool freezefl = true);
    char* str();
    int pcount() const;
  private:
    strstreambuf sb;  // exposition only
  };
}
```

1 The class `ostrstream` supports the writing of objects of class `strstreambuf`. It supplies a `strstreambuf` object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

(1.1) — `sb`, the `strstreambuf` object.

D.56.2.1 `ostrstream` constructors [depr.ostrstream.cons]

```
ostrstream();
```

1 *Effects:* Constructs an object of class `ostrstream`, initializing the base class with `ostream(&sb)` and initializing `sb` with `strstreambuf())`.

```
ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);
```

2 *Effects:* Constructs an object of class `ostrstream`, initializing the base class with `ostream(&sb)`, and initializing `sb` with one of two constructors:

(2.1) — If `(mode & app) == 0`, then `s` shall designate the first element of an array of `n` elements. The constructor is `strstreambuf(s, n, s)`.

(2.2) — If `(mode & app) != 0`, then `s` shall designate the first element of an array of `n` elements that contains an NTBS whose first element is designated by `s`. The constructor is `strstreambuf(s, n, s + std::strlen(s))`.[339]

339) The function signature `strlen(const char*)` is declared in `<cstring>` (21.261).

D.56.2.2 Member functions [depr.ostrstream.members]

`strstreambuf* rdbuf() const;`

1 *Returns:* `(strstreambuf*)&sb` .

`void freeze(bool freezefl = true);`

2 *Effects:* Calls `rdbuf()->freeze(freezefl)`.

`char* str();`

3 *Returns:* `rdbuf()->str()`.

`int pcount() const;`

4 *Returns:* `rdbuf()->pcount()`.

D.56.3 Class `strstream` [depr.strstream]

```
namespace std {
  class strstream
    : public basic_iostream<char> {
  public:
    // Types
    typedef char                                char_type;
    typedef typename char_traits<char>::int_type int_type;
    typedef typename char_traits<char>::pos_type pos_type;
    typedef typename char_traits<char>::off_type off_type;

    // constructors/destructor
    strstream();
    strstream(char* s, int n,
              ios_base::openmode mode = ios_base::in|ios_base::out);
    virtual ~strstream();

    // Members:
    strstreambuf* rdbuf() const;
    void freeze(bool freezefl = true);
    int pcount() const;
    char* str();

  private:
  strstreambuf sb;  // exposition only
  };
}
```

1 The class `strstream` supports reading and writing from objects of class `strstreambuf`. It supplies a `strstreambuf` object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

(1.1) — `sb`, the `strstreambuf` object.

D.56.3.1 `strstream` constructors [depr.strstream.cons]

`strstream();`

1 *Effects:* Constructs an object of class `strstream`, initializing the base class with `iostream(&sb)`.

```
strstream(char* s, int n,
          ios_base::openmode mode = ios_base::in|ios_base::out);
```

2 *Effects:* Constructs an object of class `strstream`, initializing the base class with `iostream(&sb)` and initializing `sb` with one of the two constructors:

(2.1) — If `(mode & app) == 0`, then `s` shall designate the first element of an array of `n` elements. The constructor is `strstreambuf(s,n,s)`.

(2.2) — If `(mode & app) != 0`, then `s` shall designate the first element of an array of `n` elements that contains an NTBS whose first element is designated by `s`. The constructor is `strstreambuf(s,n,s + std::strlen(s))`.

D.56.3.2 `strstream` destructor [depr.strstream.dest]

```
virtual ~strstream();
```

1 *Effects:* Destroys an object of class `strstream`.

```
strstreambuf* rdbuf() const;
```

2 *Returns:* `&sb`.

D.56.3.3 `strstream` operations [depr.strstream.oper]

```
void freeze(bool freezefl = true);
```

1 *Effects:* Calls `rdbuf()->freeze(freezefl)`.

```
char* str();
```

2 *Returns:* `rdbuf()->str()`.

```
int pcount() const;
```

3 *Returns:* `rdbuf()->pcount()`.

D.57 Function objects [depr.function.objects]

D.57.1 Base [depr.base]

1 The class templates `unary_function` and `binary_function` are deprecated. A program shall not declare specializations of these templates.

```
namespace std {
  template <class Arg, class Result>
  struct unary_function {
    typedef Arg    argument_type;
    typedef Result result_type;
  };
}

namespace std {
  template <class Arg1, class Arg2, class Result>
  struct binary_function {
    typedef Arg1   first_argument_type;
    typedef Arg2   second_argument_type;
    typedef Result result_type;
  };
}
```

D.57.2 Function adaptors [depr.adaptors]

1 The adaptors ptr_fun, mem_fun, mem_fun_ref, and their corresponding return types are deprecated. [*Note:* The function template `bind` 20.357.4 provides a better solution. — *end note*]

D.57.2.1 Adaptors for pointers to functions [depr.function.pointer.adaptors]

1 To allow pointers to (unary and binary) functions to work with function adaptors the library provides:

```
template <class Arg, class Result>
class pointer_to_unary_function : public unary_function<Arg, Result> {
public:
  explicit pointer_to_unary_function(Result (*f)(Arg));
  Result operator()(Arg x) const;
};
```

2 `operator()` returns `f(x)`.

```
template <class Arg, class Result>
  pointer_to_unary_function<Arg, Result> ptr_fun(Result (*f)(Arg));
```

3 *Returns:* `pointer_to_unary_function<Arg, Result>(f)`.

```
template <class Arg1, class Arg2, class Result>
class pointer_to_binary_function :
  public binary_function<Arg1,Arg2,Result> {
public:
  explicit pointer_to_binary_function(Result (*f)(Arg1, Arg2));
  Result operator()(Arg1 x, Arg2 y) const;
};
```

4 `operator()` returns `f(x,y)`.

```
template <class Arg1, class Arg2, class Result>
  pointer_to_binary_function<Arg1,Arg2,Result>
    ptr_fun(Result (*f)(Arg1, Arg2));
```

5 *Returns:* `pointer_to_binary_function<Arg1,Arg2,Result>(f)`.

6 [*Example:*

```
int compare(const char*, const char*);
replace_if(v.begin(), v.end(),
  not1(bind2nd(ptr_fun(compare), "abc")), "def");
```

replaces each `abc` with `def` in sequence `v`. — *end example*]

D.57.2.2 Adaptors for pointers to members [depr.member.pointer.adaptors]

1 The purpose of the following is to provide the same facilities for pointer to members as those provided for pointers to functions in D.57.2.1.

```
template <class S, class T> class mem_fun_t
        : public unary_function<T*, S> {
public:
  explicit mem_fun_t(S (T::*p)());
  S operator()(T* p) const;
};
```

2 `mem_fun_t` calls the member function it is initialized with given a pointer argument.

```
template <class S, class T, class A> class mem_fun1_t
      : public binary_function<T*, A, S> {
public:
  explicit mem_fun1_t(S (T::*p)(A));
  S operator()(T* p, A x) const;
};
```

3 `mem_fun1_t` calls the member function it is initialized with given a pointer argument and an additional argument of the appropriate type.

```
template<class S, class T> mem_fun_t<S,T>
   mem_fun(S (T::*f)());
template<class S, class T, class A> mem_fun1_t<S,T,A>
   mem_fun(S (T::*f)(A));
```

4 `mem_fun(&X::f)` returns an object through which `X::f` can be called given a pointer to an `X` followed by the argument required for `f` (if any).

```
template <class S, class T> class mem_fun_ref_t
      : public unary_function<T, S> {
public:
  explicit mem_fun_ref_t(S (T::*p)());
  S operator()(T& p) const;
};
```

5 `mem_fun_ref_t` calls the member function it is initialized with given a reference argument.

```
template <class S, class T, class A> class mem_fun1_ref_t
      : public binary_function<T, A, S> {
public:
  explicit mem_fun1_ref_t(S (T::*p)(A));
  S operator()(T& p, A x) const;
};
```

6 `mem_fun1_ref_t` calls the member function it is initialized with given a reference argument and an additional argument of the appropriate type.

```
template<class S, class T> mem_fun_ref_t<S,T>
   mem_fun_ref(S (T::*f)());
template<class S, class T, class A> mem_fun1_ref_t<S,T,A>
   mem_fun_ref(S (T::*f)(A));
```

7 `mem_fun_ref(&X::f)` returns an object through which `X::f` can be called given a reference to an `X` followed by the argument required for `f` (if any).

```
template <class S, class T> class const_mem_fun_t
      : public unary_function<const T*, S> {
public:
  explicit const_mem_fun_t(S (T::*p)() const);
  S operator()(const T* p) const;
};
```

8 `const_mem_fun_t` calls the member function it is initialized with given a pointer argument.

```
template <class S, class T, class A> class const_mem_fun1_t
      : public binary_function<const T*, A, S> {
public:
  explicit const_mem_fun1_t(S (T::*p)(A) const);
```

```
  S operator()(const T* p, A x) const;
};
```

9 `const_mem_fun1_t` calls the member function it is initialized with given a pointer argument and an additional argument of the appropriate type.

```
template<class S, class T> const_mem_fun_t<S,T>
   mem_fun(S (T::*f)() const);
template<class S, class T, class A> const_mem_fun1_t<S,T,A>
   mem_fun(S (T::*f)(A) const);
```

10 `mem_fun(&X::f)` returns an object through which `X::f` can be called given a pointer to an `X` followed by the argument required for `f` (if any).

```
template <class S, class T> class const_mem_fun_ref_t
      : public unary_function<T, S> {
public:
  explicit const_mem_fun_ref_t(S (T::*p)() const);
  S operator()(const T& p) const;
};
```

11 `const_mem_fun_ref_t` calls the member function it is initialized with given a reference argument.

```
template <class S, class T, class A> class const_mem_fun1_ref_t
      : public binary_function<T, A, S> {
public:
  explicit const_mem_fun1_ref_t(S (T::*p)(A) const);
  S operator()(const T& p, A x) const;
};
```

12 `const_mem_fun1_ref_t` calls the member function it is initialized with given a reference argument and an additional argument of the appropriate type.

```
template<class S, class T> const_mem_fun_ref_t<S,T>
   mem_fun_ref(S (T::*f)() const);
template<class S, class T, class A> const_mem_fun1_ref_t<S,T,A>
    mem_fun_ref(S (T::*f)(A) const);
```

13 `mem_fun_ref(&X::f)` returns an object through which `X::f` can be called given a reference to an `X` followed by the argument required for `f` (if any).

D.58 Binders [depr.lib.binders]

The binders `binder1st`, `bind1st`, `binder2nd`, and `bind2nd` are deprecated. [*Note:* The function template `bind` (20.358.0.1) provides a better solution. — *end note*]

D.58.1 Class template `binder1st` [depr.lib.binder.1st]

```
template <class Fn>
class binder1st
  : public unary_function<typename Fn::second_argument_type,
                          typename Fn::result_type> {
protected:
  Fn                      op;
  typename Fn::first_argument_type value;
public:
  binder1st(const Fn& x,
            const typename Fn::first_argument_type& y);
```

```
    typename Fn::result_type
      operator()(const typename Fn::second_argument_type& x) const;
    typename Fn::result_type
      operator()(typename Fn::second_argument_type& x) const;
  };
```

1 The constructor initializes `op` with `x` and `value` with `y`.

2 `operator()` returns `op(value,x)`.

D.58.2 `bind1st` [depr.lib.bind.1st]

```
template <class Fn, class T>
  binder1st<Fn> bind1st(const Fn& fn, const T& x);
```

1 *Returns:* `binder1st<Fn>(fn, typename Fn::first_argument_type(x))`.

D.58.3 Class template `binder2nd` [depr.lib.binder.2nd]

```
  template <class Fn>
  class binder2nd
    : public unary_function<typename Fn::first_argument_type,
                            typename Fn::result_type> {
  protected:
    Fn                       op;
    typename Fn::second_argument_type value;
  public:
    binder2nd(const Fn& x,
              const typename Fn::second_argument_type& y);
    typename Fn::result_type
      operator()(const typename Fn::first_argument_type& x) const;
    typename Fn::result_type
      operator()(typename Fn::first_argument_type& x) const;
  };
```

1 The constructor initializes `op` with `x` and `value` with `y`.

2 `operator()` returns `op(x,value)`.

D.58.4 `bind2nd` [depr.lib.bind.2nd]

```
template <class Fn, class T>
  binder2nd<Fn> bind2nd(const Fn& op, const T& x);
```

1 *Returns:* `binder2nd<Fn>(op, typename Fn::second_argument_type(x))`.

2 [*Example:*

```
find_if(v.begin(), v.end(), bind2nd(greater<int>(), 5));
```

finds the first integer in vector `v` greater than 5;

```
find_if(v.begin(), v.end(), bind1st(greater<int>(), 5));
```

finds the first integer in `v` less than 5. — *end example*]

D.59 `auto_ptr` [depr.auto.ptr]

The class template `auto_ptr` is deprecated. [*Note:* The class template `unique_ptr` (20.127.1) provides a better solution. — *end note*]

D.59.1 Class template auto_ptr [auto.ptr]

1 The class template auto_ptr stores a pointer to an object obtained via new and deletes that object when it itself is destroyed (such as when leaving block scope 6.419).

2 The class template auto_ptr_ref is for exposition only. An implementation is permitted to provide equivalent functionality without providing a template with this name. The template holds a reference to an auto_ptr. It is used by the auto_ptr conversions to allow auto_ptr objects to be passed to and returned from functions.

```
namespace std {
  template <class Y> struct auto_ptr_ref;    // exposition only

  template <class X> class auto_ptr {
  public:
    typedef X element_type;

    // D.60.0.1 construct/copy/destroy:
    explicit auto_ptr(X* p =0) throw();
    auto_ptr(auto_ptr&) throw();
    template<class Y> auto_ptr(auto_ptr<Y>&) throw();
    auto_ptr& operator=(auto_ptr&) throw();
    template<class Y> auto_ptr& operator=(auto_ptr<Y>&) throw();
    auto_ptr& operator=(auto_ptr_ref<X> r) throw();
   ~auto_ptr() throw();

    // D.61.0.1 members:
    X& operator*() const throw();
    X* operator->() const throw();
    X* get() const throw();
    X* release() throw();
    void reset(X* p =0) throw();

    // D.61.0.2 conversions:
    auto_ptr(auto_ptr_ref<X>) throw();
    template<class Y> operator auto_ptr_ref<Y>() throw();
    template<class Y> operator auto_ptr<Y>() throw();
  };

  template <> class auto_ptr<void>
  {
  public:
    typedef void element_type;
  };
}
```

3

The class template auto_ptr provides a semantics of strict ownership. An auto_ptr owns the object it holds a pointer to. Copying an auto_ptr copies the pointer and transfers ownership to the destination. If more than one auto_ptr owns the same object at the same time the behavior of the program is undefined. [*Note:* The uses of auto_ptr include providing temporary exception-safety for dynamically allocated memory, passing ownership of dynamically allocated memory to a function, and returning dynamically allocated memory from a function. Instances of auto_ptr meet the requirements of MoveConstructible and MoveAssignable, but do not meet the requirements of CopyConstructible and CopyAssignable. — *end note*]

D.60.0.1 auto_ptr constructors [auto.ptr.cons]

`explicit auto_ptr(X* p =0) throw();`

1 *Postconditions:* `*this` holds the pointer `p`.

`auto_ptr(auto_ptr& a) throw();`

2 *Effects:* Calls `a.release()`.

3 *Postconditions:* `*this` holds the pointer returned from `a.release()`.

`template<class Y> auto_ptr(auto_ptr<Y>& a) throw();`

4 *Requires:* `Y*` can be implicitly converted to `X*`.

5 *Effects:* Calls `a.release()`.

6 *Postconditions:* `*this` holds the pointer returned from `a.release()`.

`auto_ptr& operator=(auto_ptr& a) throw();`

7

Requires: The expression `delete get()` is well formed.

1 *Effects:* `reset(a.release())`.

2 *Returns:* `*this`.

`template<class Y> auto_ptr& operator=(auto_ptr<Y>& a) throw();`

3 *Requires:* `Y*` can be implicitly converted to `X*`. The expression `delete get()` is well formed.

4 *Effects:* `reset(a.release())`.

5 *Returns:* `*this`.

`~auto_ptr() throw();`

6 *Requires:* The expression `delete get()` is well formed.

7 *Effects:* `delete get()`.

D.61.0.1 `auto_ptr` members [auto.ptr.members]

`X& operator*() const throw();`

1 *Requires:* `get() != 0`

2 *Returns:* `*get()`

`X* operator->() const throw();`

3 *Returns:* `get()`

`X* get() const throw();`

4 *Returns:* The pointer `*this` holds.

`X* release() throw();`

5 *Returns:* `get()`

6 *Postcondition:* `*this` holds the null pointer.

`void reset(X* p=0) throw();`

7 *Effects:* If `get() != p` then `delete get()`.

8 *Postconditions:* `*this` holds the pointer `p`.

D.61.0.2 `auto_ptr` conversions [auto.ptr.conv]

```
auto_ptr(auto_ptr_ref<X> r) throw();
```

1 *Effects:* Calls `p.release()` for the `auto_ptr p` that `r` holds.

2 *Postconditions:* `*this` holds the pointer returned from `release()`.

```
template<class Y> operator auto_ptr_ref<Y>() throw();
```

3 *Returns:* An `auto_ptr_ref<Y>` that holds `*this`.

```
template<class Y> operator auto_ptr<Y>() throw();
```

4 *Effects:* Calls `release()`.

5 *Returns:* An `auto_ptr<Y>` that holds the pointer returned from `release()`.

```
auto_ptr& operator=(auto_ptr_ref<X> r) throw()
```

6 *Effects:* Calls `reset(p.release())` for the `auto_ptr p` that `r` holds a reference to.

7 *Returns:* `*this`

D.62 Violating *exception-specifications* [exception.unexpected]

D.62.1 Type `unexpected_handler` [unexpected.handler]

```
typedef void (*unexpected_handler)();
```

1 The type of a *handler function* to be called by `unexpected()` when a function attempts to throw an exception not listed in its *dynamic-exception-specification*.

2 *Required behavior:* An `unexpected_handler` shall not return. See also 15.370.1.

3 *Default behavior:* The implementation's default `unexpected_handler` calls `std::terminate()`.

D.62.2 `set_unexpected` [set.unexpected]

```
unexpected_handler set_unexpected(unexpected_handler f) noexcept;
```

1 *Effects:* Establishes the function designated by `f` as the current `unexpected_handler`.

2 *Remark:* It is unspecified whether a null pointer value designates the default `unexpected_handler`.

3 *Returns:* The previous `unexpected_handler`.

D.62.3 `get_unexpected` [get.unexpected]

```
unexpected_handler get_unexpected() noexcept;
```

1 *Returns:* The current `unexpected_handler`. [*Note:* This may be a null pointer value. — *end note*]

D.62.4 `unexpected` [unexpected]

```
[[noreturn]] void unexpected();
```

1 *Remarks:* Called by the implementation when a function exits via an exception not allowed by its *exception-specification* (15.370.1), in effect after evaluating the throw-expression (D.62.1). May also be called directly by the program.

2 *Effects:* Calls the current `unexpected_handler` function. [*Note:* A default `unexpected_handler` is always considered a callable handler in this context. — *end note*]

D.63 Random shuffle [depr.alg.random.shuffle]

The function templates `random_shuffle` are deprecated.

```
template<class RandomAccessIterator>
  void random_shuffle(RandomAccessIterator first,
                      RandomAccessIterator last);

template<class RandomAccessIterator, class RandomNumberGenerator>
  void random_shuffle(RandomAccessIterator first,
                      RandomAccessIterator last,
                      RandomNumberGenerator&& rng);
```

1 *Effects:* Permutes the elements in the range `[first,last)` such that each possible permutation of those elements has equal probability of appearance.

2 *Requires:* `RandomAccessIterator` shall satisfy the requirements of `ValueSwappable` (17.143.0.1). The random number generating function object `rng` shall have a return type that is convertible to `iterator_traits<RandomAccessIterator>::difference_type`, and the call `rng(n)` shall return a randomly chosen value in the interval `[0,n)`, for `n > 0` of type `iterator_traits<RandomAccessIterator>::difference_type`.

3 *Complexity:* Exactly `(last - first) - 1` swaps.

4

Remarks: To the extent that the implementation of these functions makes use of random numbers, the implementation shall use the following sources of randomness:

The underlying source of random numbers for the first form of the function is implementation-defined. An implementation may use the `rand` function from the standard C library.

In the second form of the function, the function object `rng` shall serve as the implementation's source of randomness.

Annex E (normative) Universal character names for identifier characters [charname]

E.1 Ranges of characters allowed [charname.allowed]

```
00A8, 00AA, 00AD, 00AF, 00B2-00B5, 00B7-00BA, 00BC-00BE, 00C0-00D6, 00D8-00F6, 00F8-00FF

0100-167F, 1681-180D, 180F-1FFF

Annex F (informative) Cross references [xref]

This annex lists each section label and the corresponding section number, in alphabetical order by label. All of the section labels are the same as in the 2003 standard, except:

— labels that begin with `lib.` in the 2003 standard have had the `lib.` removed so that they do not all appear in the same part of this list. For example, in the 2003 standard, the non-modifying sequence algorithms were found in a section with the label `[lib.alg.nonmodifying]`. The label for that section is now `[alg.nonmodifying]`.

— the label for Annex B has been changed from `[limits]` to `[implimits]`. The label `[limits]` refers to section 18.41.2.
